The electricity use of Manitoba Hydro's Residential Basic sector has grown 121 GWh per year (1.8%) for the past ten years. During this time, the number of Residential Basic customers has grown by 1.0% per year with average use growing 0.8% per year (MH Rebuttal page 10, lines 3-7). Although some jurisdictions are projecting lower growth rates, the average use per customer is projected to continue to grow in Manitoba, albeit more slowly, at a rate of 0.3% per year over the next 20 years (MH Rebuttal page 10, lines 13-14). Increasing saturations of electric space and water heating have been and are expected to continue to contribute to this increase in average use in Manitoba.

Manitoba Hydro recognizes the economic benefit to the customer, the utility and Province when customers with access to natural gas choose to heat with natural gas. This was outlined in Manitoba Hydro's August 2012 "Economic, Load and Environmental Impacts of Fuel Switching in Manitoba" report. Manitoba Hydro's Heating Fuel Choice Initiative, introduced to address this trend, is a multi-faceted approach to educate all stakeholders involved in the fuel choice decision including homeowners, heating contractors, homebuilders and land developers. Economic comparisons, technical information and a variety of convenient on-bill financing options are promoted to customers to assist them in making the optimal heating fuel choice, particularly in the new home market (PUB/MH I-253b).

Under the 2013 Load Forecast, Manitoba Hydro identified a projected reduction of 366 GWh by 2032/33 arising from this initiative and Mr. Kuczek testified to plans for increased educational efforts and an additional 100 GWh adjustment anticipated for the 2014 Load Forecast (Tr. p. 394, lines 2-6). This represents achieving over 50% of the potential energy impacts assuming the campaign was 100% successful. (MH Exhibit #122). Manitoba Hydro continues to monitor the market and adjust its approach and is exploring additional strategies to ensure these market objectives are achieved. Manitoba Hydro will look at other intervention strategies including the possibility of service extensions and allowances in the event that the targets set out for the Heating Fuel Choice initiative are not achieved (Tr. p. 547, lines 12-19).

Both Mr. Todd and Mr. Chernick addressed the potential to use service extension policies and/or incentives to reduce the number of homes with electric heat in natural gas available areas. While Mr. Chernick in his written report questioned the effectiveness of Manitoba Hydro's education campaign, it became apparent on cross-examination, that these conclusions were based on a cursory review of Manitoba Hydro's overall initiative, which did not take into account the targeted strategy, and financial and technical supports available to customers noted in the response to PUB/MH I-253b. Manitoba Hydro has indicated at both this and the recent past General Rate and Cost of Service proceedings that expanded strategies, such as service policies, are being explored and will be undertaken to ensure customers understand their heating fuel options and make the optimal choice.

3.2 Reducing Growth in Electric Space and Water Heating Market Share

Manitoba Hydro submits that its projections for influencing market share of electric space and water heating are realistic given Manitoba's market conditions combined with existing and emerging Federal and Provincial regulations.

3.2.1 Space Heating

Manitoba Hydro believes there are significant economic benefits for the customer, the utility and the Province when customers who have access to natural gas service, choose natural gas equipment for their space heating (MH Exhibit #189 – Tab 6 – Page 38). In setting targets for future market share of natural gas space heating in Winnipeg and the South Gas Available area, Manitoba Hydro acknowledges two key considerations:

- Customer choice – even with full information, some customers may choose electric space heat for reasons other than economic or global environmental impact such as perceptions related to renewability, or safety and support of the local economy (GAC/MH I-077).
- Economic access to natural gas in the South Gas Available area – In Winnipeg, most customers have natural gas service near to their homes, in both existing and new developments. However, not all customers in the South Gas Available area have natural gas service adjacent to their home or to a proposed new development and therefore the cost of extending the natural gas main must be considered. As Ms. Morrison noted at Transcript page 939, the analysis of economic access to natural gas is based upon the assumption that the customer has access to a natural gas line in front of their house, or already connected to the home.

Under the 2013 Load Forecast, Manitoba Hydro projects nearly 100% of new single detached homes in Winnipeg will choose natural gas space heat and that in the South Gas Available Area the trend towards electric space heating will reverse such that less than 1/3 of new single detached homes will heat with electricity by 2020/21, reducing further to less than ¼ of new single detached homes in the years beyond 2020/21 (PUB/MH I-253a).

3.2.2 Water Heating

Manitoba Hydro recognizes that water heating fuel choice may represent an opportunity to manage increasing electricity demand. However, the Corporation also recognizes that there are other considerations for customers when examining the economics of fuel choice for water heating. Where customers have an existing natural gas service and currently use a conventional natural gas water heater, there are economic benefits to the customer to "stay with natural gas". However, as outlined in MH Exhibit #189 – Tab 6 – Page 45, the economics differ where the customer's choices are between a side-vent natural gas water heater and an electric water heater such as in new homes.

> "Customers are better positioned economically when using electricity for water heating due to the high upfront capital cost of the side-vent natural gas tank (which the customer would be saving if they switched to electric). This is common in new home construction where chimneys are no longer required for venting high efficiency natural gas furnaces, thereby limiting natural gas water heater options to the higher capital cost side-vent options."

Manitoba Hydro also outlined in its response to GAC/MH I-071, circumstances where the economics for a customer with an existing natural gas water heater may see choosing an electric water heater as more attractive. As noted in this response, the customer will assess their choices based upon their individual circumstances, including the age and condition of their existing water heater. For example if a customer's existing natural gas water heater is relatively new and the venting requirements can be met by sleeving the chimney, the customer saves $450 by choosing to sleeve the chimney instead of installing a new electric water heater. However, if the existing natural gas water heater is near end of life and venting adjustments are required, installing a new conventional natural gas water heater and sleeving the chimney costs $450 more than installing an electric water heater.

The upfront capital cost difference between natural gas and electric water heating options is expected to become even greater in the future as the Federal Government pursues increased efficiency regulations for natural gas water heaters. (MH Exhibit #189 – Tab 6 – Page 50)

> "NRCan is proposing a minimum efficiency factor (EF) of 0.67 for residential natural gas water heaters effective April 1, 2016, and a minimum EF of 0.8 effective January 1, 2020. This regulation is aggressive considering most residential water heaters currently available on the market have an EF between 0.57 and 0.60."

Higher efficiency natural gas water heaters come at a much higher price than even the side-vent natural gas water heaters, where:

> "A preliminary market review indicated that water heaters with an EF of 0.67 can cost approximately $800 more than a side vent natural gas hot water tank… water heaters currently available in Manitoba that offer an EF of 0.80 are condensing natural gas water heaters which can cost up to an additional $3000 compared to a side vent natural gas water tank."

> "The large incremental product costs … are anticipated to further accelerate the market conversion to electric water heating"

These regulations will apply to all natural gas water heaters, for both existing and new homes. As a result, and notwithstanding Manitoba Hydro's pursuit of increased marketing efforts in an attempt to reduce the projected market share of electric water heating, Manitoba Hydro believes its projections for electric and natural gas water heating are reasonable.

3.3 Conclusion

Based upon these emerging market factors and Manitoba Hydro's accelerating efforts under its Heating Fuel Choice Initiative, Manitoba Hydro is confident in the projected reduction of 366 GWh by 2032/33 as outlined in the 2013 Load Forecast, and the further 100 GWh identified by Mr. Kuczek in his presentation of March 4, 2014 (MH Exhibit #87, slide 12). However, even with these efforts, the average use per customer is projected to continue to grow in Manitoba over the next 20 years.

4.0 DSM

4.1 Manitoba Hydro is aggressively pursuing DSM opportunities under the recently released 2014 PS plan

Manitoba Hydro has a long history of aggressively pursuing economic DSM opportunities through a broad and comprehensive strategy. This was acknowledged by GAC in its final argument, and by Mr. Dunsky in his evidence who testified:

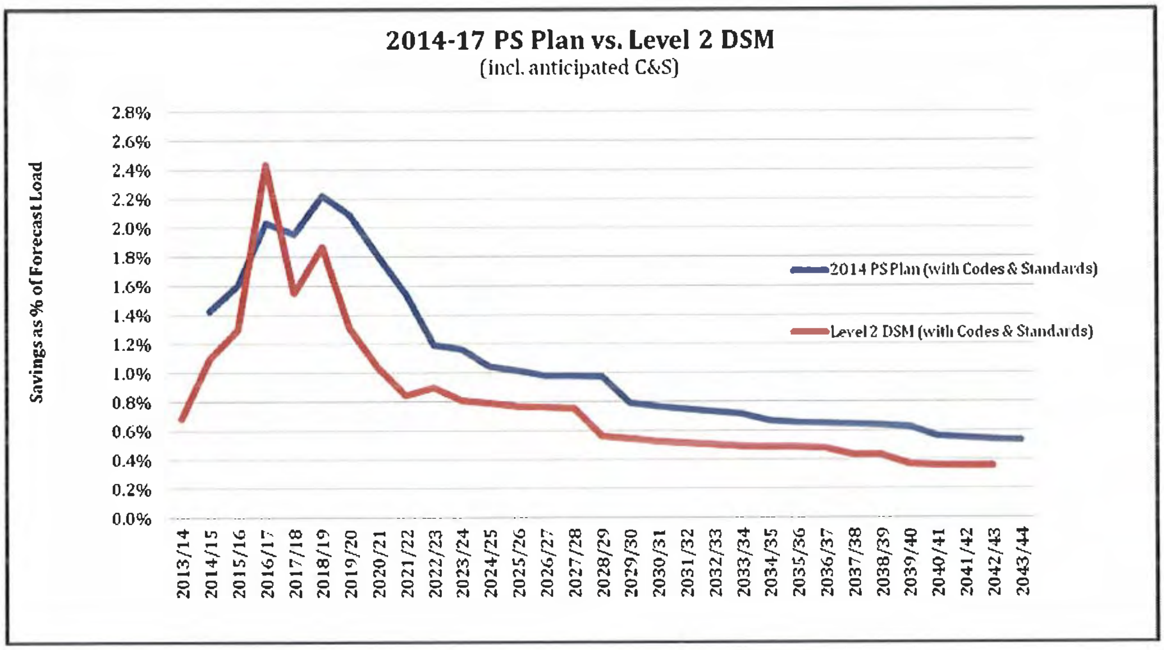
> "...Manitoba Hydro has a very strong history with -- with energy efficiency, dating back a fairly long time. It had, in previous years, received very strong ratings, several awards." (Tr. p. 7977-7988)

This success is demonstrated through the energy savings achieved to date of 2,269 GWh (MH Exhibit #203) which has allowed participating customers to save $660 million cumulatively on their electricity bills since launching its first program in 1989. Manitoba Hydro is committed to continuing its aggressive pursuit of all economic DSM opportunities in its overall efforts to meet Manitoba's future electricity demand in the most economic manner and to assist customers with managing their energy bills. As outlined in Manitoba Hydro's Rebuttal Evidence (MH Exhibit #85, pages 27-28), Manitoba Hydro has identified additional DSM opportunities and subsequent to the filing of the NFAT submission has analyzed three increased levels of DSM beyond the existing DSM portfolio included in the original submission. These increased levels of DSM represent significant increases over the program as outlined in the 2013 Power Smart Plan; with enhanced scenarios ranging from 2.2 to 4.6 times the program savings outlined in the 2013 Power Smart Plan (MH Exhibit #85, page 29).

Following the development of the higher levels of DSM for the scenario analysis, and as pursuant to the Energy Savings Act, Manitoba Hydro consulted with the Province of Manitoba (Tr. p. 9855, lines 18-22) in the creation of the 3-year 2014-2017 Power Smart Plan (MH Exhibit #153) which involves DSM savings of 411 MW and 1064 GWh over the three year period. This represents Manitoba Hydro's current Corporate approved DSM plan which Manitoba Hydro will be pursuing over the next three years. The energy savings to be achieved in the 2014-2017 Plan represent 4% of the forecast load by 2016/17, offsetting 86% of projected load growth during the period. One of the new initiatives contributing to increased program savings is a load displacement program involving economic customer-sited generation where low-cost or no-cost energy streams may be converted into heat and electricity, displacing energy that customers would otherwise purchase from Manitoba Hydro (MH Exhibit #153, p. 40). Incentives provided under the load displacement program will be determined with consideration of all related benefit streams, both energy and non-energy. Incentives may be structured as one-time payments to reduce capital costs, ongoing payments to reduce operating and fuel-related costs, or a combination of the two. The 2014 – 2017 Power Smart Plan does not contemplate a feed-in tariff arrangement.

Subsequent to the release of the 3-year plan, Manitoba Hydro developed the 2014 - 2017 Power Smart Plan 15-Year Supplemental Report (MH Exhibit #180). This Supplemental 15 year report is used for internal resource planning purposes and involves energy savings of 1,136 MW and 3,978 GWh by 2028/29. The energy savings represent 13% of the load forecast by 2028/29, offsetting 66% of projected load growth during the period.

The Figure below, which was filed as Manitoba Hydro Exhibit # 202 provides a comparison of the Level 2 DSM included in the NFAT analysis and the 2014 – 2017 Power Smart Plan.



MH Exhibit # 202

The energy savings to be achieved through the 2014 – 2017 Power Smart Plan (15-Year Supplemental Report) is similar to the Level 2 DSM analysis presented during the course of this hearing. Manitoba Hydro Exhibit # 202 provides a comparison of the projected energy savings (GWh) under the 2014 – 2017 Power Smart Plan (15-Year Supplemental Report) and the Level 2 DSM analysis as a percent of forecast load. This comparison reflects the forecast for energy savings expected to be achieved through both programming and codes & standards investments and efforts. The 2014 – 2017 Power Smart Plan (15-Year Supplemental Report) differs from the Level 2 DSM analysis as the latter was developed at a high level and for analysis purposes during the NFAT process. DSM Level 2 was analyzed based upon the 2013 Load Forecast and associated Codes & Standards projections. The 2014 -2017 Power Smart Plan (15-Year Supplemental Report) reflects more detailed analysis resulting in programming refinements (Tr. p. 8899 - 9900) and updated codes and standards adjustments (Tr. p. 393) as noted by Mr. Kuczek. The 2014 – 2017 Power Smart Plan (15-Year Supplemental Report) reflects more detailed analysis resulting in programming refinements (Tr. p. 8899-9900) and updated codes and standards adjustments (Tr. p. 393) as noted by Mr. Kuczek.

The Curtailable Rates Program is included within the 2014 – 2017 Power Smart Plan, with projected capacity savings re-earned each year (one year life). However, as outlined in Manitoba Hydro's Rebuttal Evidence (MH Exhibit # 85, p. 47), Manitoba Hydro does not include the demand benefits available from the Curtailable Rates Program in the assessment and development of its Resources Plan. There are no energy savings forecast to be achieved through the Curtailable Rates Program.

The 2014 – 2017 Power Smart Plan (15-Year Supplemental Report) includes forecast energy and demand savings from approved and potential programs (e.g. conservation rates and fuel switching). As noted by Mr. Kuczek during the hearing, the fuel switching and conservation rates programs are not approved internally at this time. These programs require further analysis and discussion both internally and externally. The plan includes the programs as placeholders and represents Manitoba Hydro's forecast of the timing, cost and energy savings which will be achieved through these initiatives (Tr. p. 9902, lines 14-25).

Manitoba Hydro is well positioned to aggressively pursue the higher levels of DSM outlined in the 2014-2017 Power Smart Plan. As Mr. Kuczek testified, (Tr. p. 9866, lines 15-18, 23-25) the funding to deliver the programs outlined in the 2014-2017 Plan is approved and additional staffing will be required. Manitoba Hydro's Executive and Board are committed to pursuing all economic DSM opportunities and the strategies outlined with the Corporation's approved 2014 – 2017 Power Smart plan are currently being executed. As Mr. Kuczek indicated, Manitoba Hydro will leverage the use of external resources such as the AKI Energy Organization, or contract services such as those supporting the existing Water & Energy Saver and Refrigerator Retirement Programs (Tr. p. 9866-9867) where appropriate to implement and deliver the programs. Individual programs will continue to be modified to address the unique market barriers to increase market penetration of the energy efficient measures/technologies being promoted (Tr. p. 9868). Manitoba Hydro has demonstrated an ongoing commitment to finding appropriate resources and effective means to deliver the programs and savings. It is also recognized that Manitoba Hydro's DSM staff is highly skilled as noted by Mr. Dunsky (CAC Exhibit #19, page 33). Having significant experience in pursuing DSM opportunities, Manitoba Hydro is well positioned to achieve the energy savings outlined within the 2014-2017 Power Smart Plan. Barriers to achieving the energy savings outlined with the 2014 – 2017 Power Smart Plan are external, including customer participation, government concurrence (i.e. in accordance with the Energy Saving Act) and regulatory approvals (e.g. Conservation rates are subject to the approval of the Public Utilities Board). With regard to the risks associated with customer participation rates, Manitoba Hydro is confident in achieving the energy savings projected within the 2014 – 2017 Power Smart Plan based on its extensive experience delivering DSM programming and given its flexibility to modify program designs (e.g. higher incentives, modified marketing strategies, etc.) as the programs move forward and markets respond.

4.2 Power Smart –Helping Customers Manage for Future Rate Increases

Manitoba Hydro recognizes the importance of providing options for customers to manage their energy bills, particularly in an environment with projected annual rate increases of 3.95% for the future. The portfolio of programs outlined in the 2014 - 2017 Power Smart Plan offers customers a variety of options for reducing their energy bills. Each customer's ability to reduce their energy bill depends upon the opportunities present in their homes and businesses. As outlined in the examples presented in MH Exhibit #164, an electrically-heated customer can save 42% on their annual energy bill by installing energy efficient lighting and the free Water & Energy Saver kit, upgrading their attic insulation from R20 to R50 and their basement insulation from R0 to R24, and "retiring" their second refrigerator. A customer using natural gas for space and water heating can save approximately 15% on their annual electricity costs or 5% on their overall energy bill (natural gas and electricity) by installing energy efficient lighting and retiring their second refrigerator. Manitoba Hydro promotes a number of no cost/low cost actions which can also help reduce customers' energy bills, such as lowering your thermostat by 3 degrees during the night or when you will be away during the day. All of these initiatives and programs are in place to aid customers in managing future energy bills and as Ms. Morrison testified (Tr.p.9919 and Tr. p. 9924 and 9925) Manitoba Hydro expects to have an even stronger message targeted to customers on how Manitoba Hydro can help them to reduce their energy use and thereby reduce the impact on their overall energy bill.

4.3 Comparing DSM Targets Across Jurisdictions

A focus of discussion by Intervenors during the course of these proceedings was a comparison of Manitoba Hydro's DSM targets and projections to those of other jurisdictions. Manitoba Hydro cautions that it is dangerous, and potentially misleading to compare among various jurisdictions using a metric such as "savings as a % of sales", as this will not recognize differences among regions in load characteristics and marginal cost considerations. It must also be recognized that utilities and energy efficiency agencies report savings differently, and treat the impact of interactive effects differently which will also impact upon comparisons between jurisdictions. (MH Exhibit #85 page 36)

Manitoba Hydro highlighted the differences in energy savings targets reported using gross methodology versus using net methodology in its Rebuttal Evidence (MH Exhibit #85, page 34 lines 27-33). That evidence includes a quote from a report produced by ACEEE, which

Mr. Dunsky describes as *"the premiere organization in DSM"* (Tr. p. 8148,lines 20-21), as follows;

> "..these substantial discrepancies between states in the use of net vs. gross savings (and the approaches used to calculate net savings) clearly underscore the difficulty of making "apples to apples" comparisons…" (Manitoba Hydro Rebuttal Evidence, MH Exhibit #85, page 34 line 34 to page 35 lines 1-2).

The report concludes with a recommendation on the issue of net vs. gross that;

> "…whichever approach a state uses, its methodologies and assumptions on this issue should be fully disclosed, so that others seeking to interpret reported results will have that understanding, and be able take that into consideration when comparing results across states." (Manitoba Hydro Rebuttal Evidence, MH Exhibit #85 page 35, lines 3-6).

Manitoba Hydro recognizes that all metrics, not just the % of sales metric discussed at length in these proceedings, must be viewed with caution recognizing the differences noted. The Corporation has concluded that a more relevant and useful approach to assessing its efforts relative to other regions is best accomplished by comparing its specific DSM programming, and its comprehensiveness, against DSM programming in other comparable regions.

4.4 DSM for the Long Term –Treatment of Technological Innovation

Manitoba Hydro's long-term commitment to DSM has been demonstrated in its active engagement in DSM programming for over more than 20 years, even during the uncertainty that arose in the restructuring of the electricity markets in the 1990's. This commitment to DSM will continue into the future. During these proceedings, there has been significant discussion around Manitoba Hydro's longer term projections for DSM savings. In preparing the projections of energy reductions under the 3 levels of enhanced DSM analysis and in the preparation of the 2014 -2017 Power Smart Plan – 15 Year Supplemental Report, Manitoba Hydro focused on known opportunities over the next 15 years. Most jurisdictions, as noted by Mr. Dunsky at page 8039 of the Transcript, plan for shorter horizons. As the DSM projections are included within Manitoba Hydro's resource planning process as a means of meeting future energy requirements where scale and timing are important considerations, Manitoba Hydro has traditionally focused on measures and opportunities that are known, commercially-available or very near commercialization. This practice is similar to most jurisdictions as noted by EnerNOC in Manitoba Hydro's Rebuttal Evidence (MH Exhibit #85, page 38, lines 34-35) and Mr. Dunsky (Tr. p. 8035, lines 21-22 and Tr. p. 8036, lines 1-6); although as Mr. Dunsky notes in his testimony beginning at Tr. p. 8036 (CAC Exhibit #62, slide 41) three jurisdictions are beginning to explore other approaches. It is important to note that even for those jurisdictions; the time horizon projected is shorter, using 10 year forecasts (CAC Exhibit #62, slides 43, 48 and 49; Tr. p. 8039, lines 18 – 24).

As Mr. Dunsky notes DSM is driven through innovation (Tr. p. 8001, lines 5-12). While it may only be a question of timing as to when the next innovation or evolution of energy efficient technology will become available and commercially viable, for the purposes of resource planning and meeting customers' energy needs, timing does matter. The Corporation must balance risks and the timing of technology evolution, and its adoption can have a significant impact on the Corporations obligation to meet customers' energy requirements. As a result, the Corporation has adopted the prudent practice of focusing on measures and opportunities that are known, commercially-available, or very near commercialization.

Manitoba Hydro monitors the market for emerging opportunities and incorporates these opportunities in the forecast of DSM savings when appropriate. As Mr. Kuczek testified, disruptive technology events are very difficult to forecast. Manitoba Hydro does not want to count on such technologies happening. As a result, Manitoba Hydro monitors energy technologies and incorporates them into its Plan as the risks become lower. Mr. Kuczek also suggested that Manitoba Hydro was more conservative in the past than we likely will be in the future (Tr. p. 9870, lines 5-15).

Mr. Todd acknowledged in his testimony that forecasting the "what" and the "when" of these innovations is difficult:

> "And the other side of it is that there's all of these promising technologies. I approach them with -- with caution. You know, fuel cells are something which were going to be ready for cars next year for about the last thirty (30) years. So, you know, many of the technologic innovations that are anticipated in being around the corner are not realized, and that's what makes the predictions very hard. But there's so much happening that it's hard not to believe that there will be breakthroughs on some of the efforts being made." (Tr. p. 4960, lines 6-17)

It is important to recognize that not all technological innovations reduce load. Some will in fact increase load. A prime example is the growth experienced due to technological changes in the home electronics sector (Manitoba Hydro Exhibit #85, p. 38). It is reasonable to expect that the future will also see innovations which may lead to increased electric load. Dr. Gotham in his discussion of load forecasting spoke of the electric vehicles and their impact on future load when he testified:

> "There are potential game-changing technologies that would go in the other direction, and I'm thinking in terms of, say, plug-in vehicles." (Tr. p. 8424, lines 19-22)

In his evidence, Mr. Dunsky at slide 21 (CAC Exhibit #62) presents five areas of "known" innovation that will support continuance of future DSM savings targets. Manitoba Hydro is aware of these opportunities, and has or will incorporate them as appropriate targets based on their particular relevance to Manitoba load and market.

1. New Efficiency Standards – Mr. Dunsky speaks to new efficiency standards and regulation of higher minimum performance standards as being regulatory innovations that will fundamentally affect our future energy requirements (Tr. p. 8003, lines 18-19). Substantial efficiency regulation for appliances and equipment has already been introduced over the last 20 years, which will continue to impact the market in future years, even if no further improvements are incorporated. Past savings are reflected in load growth to-date and future savings from current regulations are included in Manitoba Hydro's load forecast projections.

   As we look forward, Manitoba Hydro expects to continue realizing further savings through the introduction of new codes and standards incorporated into federal and provincial energy efficiency regulations, many of which are considered in the enhanced targets presented during these proceedings. However as Mr. Friesen stated

   > "that phenomena that Ms. Morrison spoke to, about the slice getting smaller, affects Codes and Standards as well. So I'll give you an example. If your refrigerator or other device went from 90 to 92 percent efficiency, the next time you only have [8] percent losses. If you go from ninety-two (92) to ninety-five (95), next time you only have 5 percent losses. You can't take away more than your losses essentially. That's your limiting factor. It's the law of science. 'Cause I

> think we can all agree that we're not going to get greater than 100 percent efficiency. And as we approach that threshold, the challenge becomes progressively larger from both a cost perspective and a technical perspective." (Tr. p. 9958, lines 20-25 and Tr. p. 9959, lines 1-10)

Manitoba Hydro continues to be heavily engaged at both the Federal and Provincial level, working to establish ongoing enhancements and updates to minimum energy performance standards for a broad array of energy-consuming technologies and to determine the appropriateness of their adoption into an energy efficiency code or regulation. As stated by Mr. Friesen:

> "Manitoba Hydro invests quite heavily in codes and standards development. I think if you would speak nationally, we are considered to be one (1) of the leaders with NRCan, BC Hydro, the Ontario Ministry of Energy, as funders of activities to develop new standards that are implemented in the future within federal and provincial regulations, energy efficiency regulations. So Manitoba Hydro does have a considerable investment in codes and standards. We work closely with provincial authorities. We work with federal authorities on many levels to achieve those." (Tr. p. 1128, lines 7-18).

2. LED Lighting – Manitoba Hydro has been pursuing energy efficient opportunities in the area of lighting for over 20 years through its Commercial Lighting Program and its past Roadway Lighting Conversion, Residential Compact Fluorescent Lighting and Seasonal LED lighting programs. Manitoba Hydro continues to monitor this market for emerging cost effective opportunities, including an LED Roadway Lighting Conversion Program and Residential LED Lighting program which were introduced under the recently approved 2014 -2017 Power Smart Plan.

As Ms. Morrison testified at pages 9957 – 9958, when looking at efficiency opportunities each efficiency innovation results in a "smaller slice" of energy reduction. The initial transition from incandescent lighting to compact fluorescent lighting yielded savings of 60 - 80 percent (e.g. 60 watt incandescent to 13 watt compact fluorescent). The introduction of current generation LEDs over CFLs provided incremental savings of about 5 to 10 percent when compared against the original incandescent lamp (e.g. 13 watt compact fluorescent to 8 watt LED). Now, despite a nearly 40 percent improvement in efficiency over the compact fluorescent technology , current generation LED's provide incremental savings that amount to approximately 1/10th of that provided from the earlier transition to compact fluorescent lamps. Mr. Dunsky (CAC Exhibit #62, slide 24) submits that further incremental savings of 50 percent are anticipated from LED technology is currently being projected for later in the decade as efficacy (lumens per watt) increases by 2.0 to 2.5 times. If this next stage of innovation is realized at the level suggested, incremental energy savings will be substantially smaller than those achieved through earlier innovations. Although 50% sounds like a significant improvement, it is important to consider the base on which that it being calculated to understand what it actually means in terms of energy savings.

3. Air Source/Ductless Heat Pumps – The efficiency and cost effectiveness of air source heat pump technology in Manitoba is largely dependent on the ability of the heat pump's to efficiently extract heat (energy) from a highly variable energy supply (outside ambient air) that is at its absolute lowest when Manitoba's heating requirement is at its absolute highest (cold winter temperatures). Pursuing air-source heat pump technology becomes progressively more challenging and expensive as the outside air temperatures decline, lowering the coefficient of performance and effectively increasing the amount of electrical energy required to upgrade heat extracted from progressively colder outside air, decreasing the economic benefit over ground-source heat pumps and other non-electric heating options (CAC_GAC/MH I-003b and GAC_CAC/MH II-011b). As Mr. Robson testifies in oral testimony;

> "...as the temperature drops, it takes more and more energy to pull energy -- the heat out of that air and transfer it to the house. So as it gets colder and colder, the efficiency drops and drops and drops till eventually it's just working like an electric furnace. So electric back-up resistance heat takes over." (Tr. p. 7770, lines 9-16)

In his testimony, Mr. Dunsky (Transcript Page 8018) indicates that his analysis of cost effectiveness for air source heat pumps is based on a design that meets 30 to 60 percent of the heating requirement for a residential home, thereby reducing installation costs. While this approach may lead to lower overall capital costs for installation of air source/ductless heat pumps, it is clear that such an installation will also yields lower benefits to the customer as the remainder of the home will continue to require heat, which Mr. Dunsky suggests be supplied by electric base board heat

(Tr. p 8018, lines 9-11). The reduced benefits, along with the continued requirement for auxiliary or supplemental electric heat during colder periods are not anticipated to significantly enhance the economics of air source/ductless heat pumps for residential heating in Manitoba.

In Manitoba's lowest temperatures, air source heat pumps require supplemental heat (typically electric resistance) which offsets the potential benefits that other heating options can provide during periods of peak system demand. As such, air source heat pumps are not presently economic in Manitoba (NFAT Application, Chapter 4, page 26, lines 18-19) and will require considerable advancement in performance and reductions in cost to achieve levels necessary for wide-spread market adoption.

4. Data Driven Analytics – Data-driven analytics continue to be reviewed by Manitoba Hydro as a tool to enhance engagement with customers and support greater understanding of how customer behavior impacts consumption. The technologies and platforms through which consumers can assess their energy consumption data is evolving at a pace that is consistent with information technology and smart home communication systems. Manitoba Hydro assessed this type of energy efficiency measure for the residential market in the DSM Potential Study under Home Energy Management Systems with a result of 34 GWh of Achievable savings potential as of 2031/32 (Appendix 4.3, page 6-10). The adoption of data analytics is supported by plans to enhance Manitoba Hydro's industrial and commercial programs under the 2014 - 2017 Power Smart Plan. As Ms. Morrison testified (Tr. p. 9970-9972), Manitoba Hydro has also had numerous discussions with OPower on their energy bill comparison product for the Manitoba market. The concern raised is that under these initiatives the savings must be re-earned each year in order to maintain energy savings into the future. Also as more DSM initiatives are pursued to "send the right message" to customers, such as through conservation rates, Manitoba Hydro must ensure that projected energy savings are not counted in more than once in multiple initiatives. Manitoba Hydro continues to investigate these opportunities.

5. Solar PV - Where the promotion of customer-sited generation displaces energy that would otherwise be purchased from the utility grid, it is important to recognize the competing economics of grid power and customer-sited generation along with other drivers that may encourage customers to abandon the security and reliability of the utility grid. The phenomenon of grid parity, where the delivered cost of energy from customer-sited generation becomes equal to that of energy provided from centralized

generation supporting the utility grid, was a topic of significant discussion during these proceedings, with numerous witnesses speaking to the subject in the context of structural change that may potentially strand utility assets built in anticipation of future load growth that might not materialize if customers choose to self-generate. In his testimony, Mr Colaiacovo cited the potential for such changes in the utility sector:

> "… and in higher cost jurisdictions, I think it's a very real and significant possibility. You know, where in a place like Ontario, the pure electicity commodity separated from transmission and distribution is an average of seven(7) to eight(8) cents, and during daytime peaks, will be substantially higher than that. Grid parity starts to look like a real issue, because if the cost of distributed generation of whatever sort it happens to be is cheaper, well, you know, then – then it makes sense, as long as you continue to have access to the grid for backup.." (Tr. p 7319, lines 10-21)

Mr. Colaiacovo's last point is particularly important as it clearly illustrates that the union between distributed generation and the centralized utility cannot be easily separated. The variability of solar energy, particularly during peak winter months when the peak generally occurs after dark, will not eliminate the need for generation, transmission and distribution system connectivity and support. Integrating distributed generation sources such as solar will become progressively more complicated as penetration of solar installations increase. Mr. Colaiacovo points to this challenge in his testimony:

> "…One(1) of the things that's likely to happen as a result of that is changes to rate structures, changes to cost responsibility, because the reality is, there's enormous investments in iron in the ground, whether those are distribution or transmission, and – or – or generation, and people benefit from those things. And you know, you can't just put solar panels on your roof, use them for six(6) hours a day, and not have any cost consequences, which is the way it is working today, because it's a cottage industry..." (Tr. p. 7320, lines 6-16)

Mr. Colaiacovo also testified that the utility industry will have to adapt its rate structures to accommodate integration:

> "… But if it becomes a real competitive threat to utilities, will there be changes in the market to compensate for that, to – to react to that? I think there has to be. It's the number 1 issue in the United States amongst utilities, is: How do we deal with the distorted incentives of distributed generation and sol – solar panels on the roof, because it is changing the utility business and its having consequences? By building a long-term, effectively merchant facility, are you exposing yourself to that risk? Absolutely, you are exposing yourself to that risk. However, there are billions and billions of dollars of utility shareholders in the United States who are exposed to that risk and are planning to do something about it. So in – in some measure, you have to try and put it in that broader context." (Tr. p. 7320, lines 17-25 and Tr. p. 7321, lines 1-8).

"Grid parity" represents a point in time when a customer may reasonably be expected to begin considering self-generation. As Mr. Dunsky (CAC Exhibit#19, Figure 15) indicated in his written evidence, it is anticipated that adoption of self-generation technologies such as solar photovoltaic will be highly variable from jurisdiction to jurisdiction based on the anticipated onset of grid parity alone, with differences dependent on current utility rates and projected rate increases, incentive structures, regional carbon taxes and emission regulations (fossil fuel-based generation), mandated renewable portfolios, opportunities for obtaining renewable energy supply at the utility scale, and very significantly, on the relative costs and benefits provided by technologies used for self-generation.

Several of these factors have supported the successful introduction of customer-sited solar photovoltaic technologies in other jurisdictions where mandated renewable energy portfolios, high utility rates and substantive financial incentives, have accelerated the onset of grid parity. Manitoba Hydro has already achieved extremely high levels of renewable generation without the introduction of solar technologies and maintained comparably low rates, and is therefore in a somewhat different position than utilities in jurisdictions with more limited options for renewable supply.

As Mr. Friesen indicated in his testimony (Tr. p. 606-607) the rate of technology adoption after grid parity is achieved will be highly variable and is anticipated to be gradual as competing technologies improve and become more cost-effective relative to other supply options. Mr. Dunsky supports this position in his written evidence

(CAC Exhibit #19, Page 15) and provides further comment in oral testimony with respect to grid parity in Minnesota and the rate that adoption would impact the demand for grid power.

> "... the sorts of changes that we're talking about are not going to dramatically change the -- the picture on the ground when we talk about solar, for example. If we have solar parity in Minnesota today, that doesn't mean that tomorrow morning everyone runs out and puts solar panels on the roofs for the very same reason that energy efficiency is very cheap for people to do today, and they are still not doing it on their own. These things take time. You know, there's -- there's an adoption curve. " (Tr. p. 8188, lines 3-14)

The rate of cost decline for solar photovoltaic technologies and the anticipated rate of adoption by residential and commercial customers have significant uncertainty associated with them, which uncertainty is extenuated by Manitoba Hydro's low utility rates and northern latitude (low day light hours) during critical peak periods of winter consumption.

Testimony by Mr. Dunsky and others points towards grid parity for residential solar starting in Manitoba at some point around 2020, and starting potentially as late as 2025 and beyond, depending on the rate of cost decline for solar photovoltaic equipment and projections for utility rate increases (CAC Exhibit #62, Slide 37). It is therefore reasonable to expect, based on the anticipation of a gradual adoption rate as cited by Mr. Dunsky and Elenchus (Tr. p. 5132 - 5133), that customer-sited solar photovoltaic will not substantively impact the grid requirement for power in Manitoba until some period after 2030, which is on the outer fringes for targeting future DSM savings.

The competitiveness of solar photovoltaic energy nearly 15 to 20 years into the future is uncertain, especially given the uncertainty with respect to the future solar PV, distribution integration and power system back-up costs, and future changes to the utility rate structure.

Mr. Friesen also points to considerations about the suitability of solar in his testimony that highlight the importance of recognizing the intermittency in supply;

> "If the you look at the consumption characteristic of a top consumer, a top consumer has a very high load factor. So their - generally, their load factor is point eight (.8) or higher, often as high as point nine (.9). So they have a fairly continuous requirement for energy at or near their peak capacity requirements on an almost twenty-four (24) hour basis. Solar's a very intermittent supply. As a result, I would not expect that a top consumer would choose solar as their first option in supplying their needs due to it -- due to its intermittency" (Tr. p. 610, lines 9-20)

In preparation for future grid parity Manitoba Hydro's DSM plan allows for continued monitoring, testing and demonstration of solar installations in Manitoba's harsh climate, backed by current programming that supports the installation of solar and other self-generation technology when they are economic. Where opportunities emerge and clarity is obtained, they will be included in future DSM target setting.

4.5 Curtailable Rates Program

Mr. Hacault notes in his final argument (TR. 11249 – lines 17-22) that the amount of load made available through the Curtailable Rate Program (CRP) from just one customer equates to the amount of load generated by Wuskwatim. He further points out (Tr. p. 11322, lines 1-4) that by curtailing this load it frees up a good part of a small dam. His implication therefore is that MH should be doing more to encourage these types of DSM Industrial programs, and not placing caps on the CRP.

Mr. Friesen, in his testimony (Tr. p. 1146, lines 18-22) explained that "dependable energy from Wuskwatim is very different than the amount of energy that we would be able to release through the Curtailable Rates Program". Wuskwatim is both a dependable energy and capacity resource, whereas the CRP only provides capacity. This makes Mr. Hacault's comparison to Wuskwatim only partially correct. From a capacity perspective this is correct. However, Mr. Hacault fails to note that the CRP only permits curtailment for a limited period, and for a limited number of curtailments. Contrast this with a generating station, over which Manitoba Hydro has complete and unlimited control.

Mr. Friesen noted (Tr. p. 1151-1152) that only certain industries are capable of curtailing their load on short notice, and that it is difficult for some industries to restore their load after a curtailment within a reasonable amount of time. This perhaps explains why there are only three customers on the program.

MH has had a permanent Curtailable Rate Program (CRP) in place since 1998. Over these 16 years, only a total of five industrial customers have ever participated in the program, even when there was no cap limitations. Today there are only three customers on the program. Although some have shown interest over the last few years, a review of the impact on their operations have prevented them from signing on, even though there was still available room for uptake on the program. MH therefore chose to make changes to the Terms and Conditions of the CRP, as proposed in its 2012/13 and 2013/14 GRA filing, to ensure that existing CRP customers could continue to obtain value from the program while continuing to provide reliability benefits for Manitoba Hydro. Manitoba Hydro agrees with MIPUG's assertion that DSM ought to be economic. The Curtailable Rate Program is no different. To remove the cap on the CRP would be to invite uneconomic DSM.

4.6 *The Energy Savings Act*

During this proceeding, there has been substantial discussion around target setting and where these responsibilities lie in other jurisdictions. Ms. Rohmund spoke to target setting in the United States, particularly that 25 of the US states have adopted energy efficiency resource standards (EERS) through regulation or legislation. The specific form or framework of these requirements can vary significantly from state to state (Tr. p. 419, lines 15-25, MH Exhibit #87, page 42). In Canada, the Province of British Columbia has set conservation objectives through its *Clean Energy Act* and Ontario has done so through its *Green Energy Act*. In Manitoba, those objectives are set out in *The Energy Savings Act*. This Act, enacted in June, 2012, guides Manitoba Hydro's DSM targets and activity and outlines the Province of Manitoba's expectations for the Manitoba Hydro Board with respect to the setting of energy efficiency targets.

> 7(1) **The board must, in consultation with the minister,**
> (a) prepare an energy efficiency plan by March 31, 2013; and
> (b) prepare an update to the plan annually after that.
>
> 7(2) The energy efficiency plan must set out
> (a) energy efficiency targets in relation to the projected use of power and natural gas by the corporation's customers in Manitoba;
> (b) a strategy for achieving the energy efficiency targets;
> (c) the programs, services and projects that the corporation will support to implement the strategy, which may include programs, services and projects that

(i) replace or improve equipment and materials related to the use of power and natural gas and the production of greenhouse gas emissions,

(ii) enhance space heat retention and heating efficiency, and

(iii) change customer behaviour relating to the use of power and natural gas and the production of greenhouse gas emissions; and

(d) the estimated annual cost of implementing the strategy and indicate how the costs will be funded.

(Transcript Page 9854 Line 18)

Section 8 of the Act also outlines how the Corporation is to report on performance to these DSM targets:

> 8(1) For each fiscal year beginning after March 31, 2013, the board must report, in writing, on the outcomes achieved under the energy efficiency plan during the fiscal year. The report must be given to the minister within 12 months of the end of the fiscal year.
>
> 8(2) The minister must table a copy of the corporation's report in the Assembly within 15 days after receiving it if the Assembly is sitting or, if it is not, within 15 days after the next sitting begins.

Mr. Kuczek confirmed that the recently released 2014 – 2017 Power Smart Plan was prepared in consultation with the Minister Responsible for Manitoba Hydro in accordance with the Act.

> "This year we – we consulted with them again to – to see if they wanted a three (3) year plan and a fifteen (15) year plan as well. And it was concluded that we would proceed with the three year plan, and so we developed that. And then subsequent to that we developed the fifteen (15) year plan." (Tr. p. 9855, lines 18 -23)

This evidence outlines Manitoba Hydro's understanding of the Province's preference to focus on the three year plan and programs to meet the targets identified. The longer term 15 year plan, also provided to government, is used by Manitoba Hydro for its resource planning.

The Chair (at Tr. p. 9984-85), posed the question whether or not the framework that's in place in Manitoba is adequate to ensure success for DSM programs by Manitoba Hydro. Manitoba Hydro submits that this is precisely the framework identified by *The Energy Savings Act*. The Act is quite new, only two years old, and has been used to ensure consultation with the Province to allow them input into energy efficiency programs and plans, and to review Manitoba Hydro's success in achieving those targets through annual reporting on the outcomes achieved, which report is tabled in the Legislature and thereby available for public review.

CAC/GAC, through the evidence of Mr. Dunsky has suggested that independent oversight and an accountability framework is required in Manitoba. Manitoba Hydro submits that the Energy Savings Act creates the framework for success that has been referred to by Mr. Dunsky in his testimony (Tr. p. 8088, lines 2-11), The Province of Manitoba has considered this issue, and has given its direction as to the framework appropriate for Manitoba in the legislation, and continues to provide its review and oversight by the ongoing consultation and reporting contemplated by *The Energy Savings Act*.

5.0 RESOURCE PLANNING

5.1 Resource Planning Methodology and Need

Manitoba Hydro has undertaken an Integrated Resource Planning process which evaluates various combinations of supply-side and demand-side options to obtain an overall optimum combination and plan. The NFAT submission filed in August 2013 focused on supply side resources and DSM options were evaluated as the information on higher levels of DSM became available. The Integrated Resource Planning process relies on the Generation Planning Criteria for the purpose of ensuring sufficient resources are available to meet Manitoba load reliably and to determine when those new resources are required.

5.2 Integrated Supply and DSM Plan Evaluation

Manitoba Hydro is committed to pursuing all economic DSM. As part of fulfilling that commitment, Manitoba Hydro has undertaken an Integrated Resource Planning process which evaluates various combinations of supply-side and demand-side options to obtain an overall optimum combination and plan.

During the course of the hearing, Manitoba Hydro provided information on three DSM options which, in combination with the original base DSM plan, enabled four DSM options to be evaluated; each with increasing levels of DSM.

Various participants have expressed concern that they do not believe Manitoba Hydro is undertaking Integrated Resource Planning. Mr. Dunsky expressed concerned that Manitoba Hydro "risks locking itself into a path of new supply that, as a result, will lock out the much less expensive option of more efficient demand". (CAC Exhibit #19, page 16)

Manitoba Hydro is undertaking integrated planning that combines supply and demand options. Manitoba Hydro has not locked itself into a new supply path. The purpose of this NFAT process is to assess and make recommendations as to which future path will be followed. This selection of resources and any commitment will depend on the outcome of the NFAT process and subsequent government decisions.

Manitoba Hydro's Power Smart Plan is in integral component of the Corporation's resource plans. Manitoba Hydro's DSM strategy is to pursue all economic DSM opportunities. The Power Smart Plan is developed following this principle and results in DSM being a preferred option relative to alternative supply side options within the integrated resource planning process. This has been the case for many years and as a result, the Power Smart Plan has and continues to be a component of the Corporation's strategy to meet the future electricity needs of Manitoba.

All the NFAT development plans and the pathways include DSM and whichever plan or pathway is ultimately pursued will involve expanding DSM.

As stated in the NFAT submission, the DSM sensitivities were intended to assess the impact on the supply option selection arising from different levels of DSM which potentially would be developed by Manitoba Hydro. Mr. Dunsky took the position and Mr. Thomson acknowledged (Tr. p. 195-196) that the 1.5x DSM and 4x DSM sensitivity evaluations in Chapter 12 did not provide an integration of DSM and supply which determines the optimum level of DSM.

An integrated evaluation of DSM and supply options to determine the optimum level of DSM could not be provided in the August 2013 NFAT submission due to the delay in the DSM Potential Study. The DSM options were assessed in combination with the supply options after the August 2013 submission and were provided to the NFAT process by Ms. Flynn on March 10, 2014 (MH Exhibit #95, Slide 129).

These Integrated Resource Plans (IRPs) are further documented in Manitoba Hydro Exhibit #104-16. Mr. Wojczynski explained that this exhibit contains evaluations of different combinations of DSM and supply options which can each be compared to any of the others to determine the overall optimum combination.

> "And so this -- this analysis is -- is an IRP, but it's an IRP that looks at gas, looks at hydro, looks at interconnections with its associated imports, exports, and everything and looks at DSM levels that are different.
>
> We have the three (3) levels of -- well, actually if you look here and I'll explain how we do that. We have under the DSM levels -- effectively we have four (4) levels of DSM. And then we have the different plans. And -- and you know the plans. I don't have to go through them all. And these are all comparable against each other. You'll notice that we have in the All Gas Base DSM we have a zero there. But all the others we have an -- an NPV number which is relative to that point.
>
> And this is using the TRC analysis, so this is the -- the TRC analysis. We've talked about benefits and costs previously. So all of these can be compared against each other."[4]

[4] Tr. p. 9872, lines 18-25 and Tr. p. 9873, lines 1-11

The DSM option evaluation results are discussed in Final Argument Sections 10.3 and 19.2.5.

The planning for DSM programs and integration with supply options will not stop with the NFAT analysis but will carry on in further stages (Manitoba Hydro Rebuttal, February 28, page 33). Manitoba Hydro will continue to evaluate both DSM and supply options and pursue the economic level of DSM.

5.3 Generation Planning Criteria

5.3.1 Manitoba Hydro's Generation Planning Criteria Ensures Reliability

Manitoba Hydro has a duty to provide for a reliable and dependable supply of power[5]. The Generation Planning Criteria is the means by which Manitoba Hydro plans its system to provide reasonable assurance that load can be met over winter peaks, during droughts or other contingencies including equipment outages and extreme loads, and recognizing that loads can be higher than forecast due, for example, to exceptionally cold weather. It should be understood that the Generation Planning Criteria is used to ensure that sufficient resources exist to respond to contingencies, but in no way does it limit Manitoba Hydro's ability to respond to these types of contingencies on an operational basis.

Manitoba Hydro's Generation Planning Criteria was discussed in the NFAT submission at Section 4.3.1 and further detailed in Appendix 4.1. Manitoba Hydro's Generation Planning Criteria consists of an energy criterion and capacity criterion, <u>both of which must be satisfied</u> in order to ensure a reliable supply of electricity adequate for the needs of the province.

Manitoba Hydro's capacity criterion requires that:

> "Manitoba Hydro will plan to carry a minimum reserve against breakdown of plant and increase in demand above forecast of 12% of the Manitoba forecast peak demand each year plus the reserve required by any export contract in effect at the time."

[5] See *The Manitoba Hydro Act* at Section 2 "to provide for the continuance of a supply of power adequate for the needs of the province".

Manitoba Hydro's Energy Criterion requires that:

> "The Corporation will plan to have adequate energy resources to supply the firm energy demand in the event that the lowest recorded coincident water supply conditions are repeated. Imports may be considered as dependable energy resources provided they utilize Firm Transmission Service and are sourced from either an Organized Power Market or a bilateral contract. The total quantity of energy considered as dependable energy from imports shall be limited to that which can be imported during the Off Peak Period, and shall not exceed the quantity of export contracts in effect at the time plus 10% of the Manitoba load."

Manitoba Hydro's Generation Planning Criteria is a fundamental reliability criteria that must be met by all components of proposed development plans. Economic substitutions which would compromise reliability are not permitted. The Generation Planning Criteria represent the minimum requirements, as determined by Manitoba Hydro in its role as a Planning Coordinator for Manitoba under the North American Electric Reliability Corporation (NERC) Reliability Functional Model, to ensure for a reliable and dependable supply of power for the needs of the province of Manitoba.

5.3.2 La Capra Associates Have No Expertise in the Determination of Need for a Large Predominately Hydro System

Manitoba Hydro notes that La Capra's Dan Peaco and John Athas were only conditionally qualified as expert witnesses with regard to large hydro projects:

> "The comments in respect of the expertise of these witnesses in the areas of large hydro projects and climate change have been noted, and the Board will attribute the weight to those areas that it judges appropriate under the circumstances.[6]"

More specifically, the Expert Testimony and Appearances listed in Mr. Peoco's curriculum vitae contains six limited references to hydro amongst some 58 appearance references, as provided in response to MH/LCA-001b. Significantly, none of the six references provided by Mr. Peaco related to resource planning in a predominately hydro system. Four of the six references are asset valuations of existing small hydro plants ranging in size from 4 MW to

[6] Transcript, April 7, 2014, p. 5551, lines 21-25.

260 MW (combined capacity of 4 hydro plants); valuations which would not involve any determination of need or involve the application of generation planning criteria in a predominately hydro system. Two of the references involve contracts with Hydro Quebec: one a contract dispute and the other an avoided cost comparison. Neither of these last two references describe any determinations of need in the hydro system or involve the application of generation planning criteria. La Capra Associates has no relevant expertise or related experience in the determination of the need for new resources in a large predominately hydro system. The Board should be very mindful of this lack of experience when it assesses the comments of La Capra, particularly with respect to the possibility of relaxing a critical reliability component of Manitoba Hydro's Generation Planning Criteria.

5.3.3 Manitoba Hydro's Planning Criteria are Appropriate and Consistent with Other Predominately Hydro Utilities

As discussed in detail in Manitoba Hydro's Rebuttal Evidence[7], Manitoba Hydro's Generation Planning Criteria are appropriate. Further, Manitoba Hydro's Generation Planning Criteria are reasonable, prudent, and consistent with both industry practice and the duties and responsibilities with which the Corporation is charged.

No party to the proceeding, including La Capra, raised any issues with regard to the capacity criterion of the Generation Planning Criteria.[8]

Manitoba Hydro shares the concerns articulated by MIPUG in its Final Argument with respect to La Capra's comments regarding Manitoba Hydro's energy criterion. While La Capra acknowledged in its report that Manitoba Hydro's energy criterion requiring dependable resources be available in the event of the driest flow conditions "is generally consistent with other hydro-dependent systems" it claimed that limitations on import energy in the energy criterion are "very conservative"[9] , and summarized the energy criterion as having "some unique and limiting features which restrict resource planning options"[10].

[7] See Section 4.1 "Manitoba Hydro's Generation Planning Criteria is Appropriate" of the Manitoba Hydro Rebuttal Evidence, dated February 28, 2014.
[8] See La Capra Associates Technical Appendix 1 - Resource Planning, pages 1-10 "There is no available evidence upon which to conclude that MH's capacity reserve requirement should be any different than the current 12% standard. La Capra believes this to be a reasonable assumption for the NFAT analysis."
[9] La Capra Associates Technical Appendix 1 - Resource Planning, pages 1-17
[10] La Capra Associates Technical Appendix 1 - Resource Planning, pages 1-57

Manitoba Hydro notes that according to the North American Electric Reliability Corporation (NERC), such an energy criterion is typical for a predominately hydro region[11]. In both Manitoba Hydro's Rebuttal Evidence[12] and during cross examination, Manitoba Hydro pointed out a number of other jurisdictions including British Columbia, Ontario, Hydro-Quebec, the Maritimes area, and the US Pacific Northwest region where there exist limitations on external supply or imports.

In its written evidence La Capra contrasted Manitoba Hydro's "desire for self sufficiency" in the event of the driest flow conditions on record with the approach adopted by BC Hydro and its target of self sufficiency during average flow conditions.[13] La Capra erroneously described the difference in the approaches as "drastic" and suggested that Manitoba Hydro's approach was overly conservative.[14] The flaw in this superficial analysis became apparent during cross examination where it was demonstrated that relative to the size of domestic load, and exposure to drought conditions, Manitoba Hydro's energy criterion actually allows greater reliance on imports than British Columbia with its self sufficiency target.[15]

At the conclusion of this lengthy cross examination and despite comparisons made in their written evidence to other hydro based systems such as BC Hydro and Bonneville Power, La Capra indicated that its comments regarding the "unique and limiting features which restrict the resource planning operations" in Manitoba Hydro's energy criterion were not made with respect to other hydro systems, but rather in comparison to a thermal system[16]:

> "MS. PATTI RAMAGE: Help me by explaining what is unique about Manitoba Hydro's energy criterion.
>
> MR. DANIEL PEACO: What's unique about it? It's -- a hydro system has -- has different criterion than other systems would.
>
> MS. PATTI RAMAGE: So it's not unique among hydro systems; it is unique as compared to a –

[11] NERC Resource and Transmission Adequacy Recommendations, June 15, 2004, page 10; NFAT Submission, Chapter 4, page 37
[12] See Section 4.1.4 "Manitoba Hydro Import Limitations are Consistent with other Predominantly Hydroelectric Utilities" of the Manitoba Hydro Rebuttal Evidence, dated February 28, 2014.
[13] La Capra Associates Technical Appendix 1, pages 1-15
[14] La Capra Associates Technical Appendix 1, pages 1-16
[15] Transcript, April 9, 2014, page 6179, lines 21-25
[16] Transcript, April 9, 2014, page 6196, lines 1-22

MR. DANIEL PEACO: Yeah, as I said before –

MS. PATTI RAMAGE: -- a thermal system, is that what you mean?

MR. DANIEL PEACO: -- that statement is in our report, and you read it.

MS. PATTI RAMAGE: If you could clarify for me. Is it -- you're saying it's not unique amongst hydro systems but hydro systems are unique as compared to, for example, a thermal system.

MR. DANIEL PEACO: Right.

MS. PATTI RAMAGE: Is that what you mean?

MR. DANIEL PEACO: Exactly."

Manitoba Hydro does not disagree with Mr. Peaco's conclusion in his oral testimony that hydro systems are unique in their use of an energy criterion as opposed to a thermal system. However Manitoba Hydro does not agree that this conclusion is consistent with La Capra's written evidence, which while acknowledging the requirement for dependable resources to be available in the driest flow conditions, nevertheless portrayed Manitoba Hydro's limitations on import energy in the energy criterion to make up potential energy shortfalls as being unique amongst hydro systems. It is important that the Board recognize that this is not the case, that such limitations are common in predominately hydro systems and that Manitoba Hydro's criteria is not overly conservative, and in fact allows greater reliance on imports than other hydro based systems such as BC Hydro. Manitoba Hydro believes that La Capra's lack of expertise and experience with large predominately hydro systems has resulted in La Capra's failure to recognize the critical need for and significance of the energy criterion as part of the Generation Planning Criteria in a predominately hydro system.

La Capra's lack of expertise in the determination of need for a large predominately hydro system was shown clearly when they made a serious error in responding to Information Request PUB/LCA-020. In this response La Capra determined the potential need dates based on various changes to planning or planning criteria assumptions. As part of the response to PUB/LCA-020, La Capra assessed the need date for new resources based on a planning criteria assumption entitled "Use Average Hydro Supply" in place of Manitoba Hydro's planning criteria assumption of dependable hydro supply. In cross examination, La Capra ultimately agreed that such a proposal would not meet the needs of the province during a drought and in fact would be reckless:

> "MS. PATTI RAMAGE: So if Hydro's physical import capability on its existing firm interconnection is only 6,443 gigawatt hours per year but it needs to rely on 11,000 gigawatt hours of firm imports during a critical drought, would you agree it's simply not feasible in these circumstances? And in fact it would be reckless for a resource planner to plan to a 2046/'47 energy need date?
>
> MR. DANIEL PEACO: Yes." (Tr. p. 6228)

5.3.4 Energy Criterion is not an Economic Consideration which can be waived

La Capra's lack of expertise in the determination of need for new resources in a large predominately hydro system was also shown in their desire to increase Manitoba Hydro's reliance on energy imports within the energy criterion of the generation planning criteria without any consideration of the reliability impacts. In fact, La Capra sees the energy criterion of the generation planning criteria as an economic consideration to be optimized, rather than a fundamental part of the generation planning criteria needed to ensure a reliable supply of power adequate for the needs of the province. This was evident when Mr. Daniel Peaco of La Capra Associates stated[17]:

> "The -- the next thing we did is we asked Hydro to relax the reliance on imports to 20 percent from their current 10 percent planning criteria, meaning they currently have a planning criteria where they will not rely on imported energy for more than 10 percent of the dependable energy in their -- in that calculation in their planning standards. And so we -- we wanted to -- to relax that to see if -- if, by relaxing that, that that led to any better performance in the -- in the plan or not."

La Capra's apparent perspective that the energy criterion of the generation planning criteria can be adjusted based on the optimization of economic considerations without consideration of the reliability impacts was further evidenced in the response Mr. Daniel Peaco provided to a question from Board Member Bel:[18]

[17] Transcript, April 7, 2014, page 5610, lines 1-10.
[18] Transcript, April 10, 2014, page 5328, lines 2-17.

> "MR. RICHARD BEL: ...The first question is about the discussion about the relaxing the import constraint. Okay. And a simple question. Is there any risk or negative to relaxing that import constraint?...
>
> MR. DANIEL PEACO: The -- the policy is just that; it's a policy. And what we tried to do in our investigation was to test the policy to see, you know, how much of the -- the policy is -- is an economic-based policy and how much of it is -- is a reliability-based policy."

As previously stated, Manitoba Hydro's Generation Planning Criteria, including all parts of the energy criterion, is a fundamental reliability criteria that must be met by all proposed development plans.

Even though La Capra acknowledged that hydro systems are subject to an energy criterion, they treated the energy criterion as an economic consideration to be optimized rather than a criterion that must balance an adequate level of reliability with economics[19]:

> "MR. DANIEL PEACO: ... the No Gen case we did was a construct to say, I just want to see -- test how the system performs if you do relax the policy. It doesn't go beyond that to say, When do you hit, you know, physical risk or other kinds of risk.
>
> But it would say -- but it -- but it would at least tell us, if you could relax it, you know, does it -- does it tend to -- to bring more benefits. And I think in this case it really pointed to the fact that it -- it -- to the extent you can relax it, it can improve the economics and the performance of the plan."

La Capra has missed the point of the energy criterion of the Generation Planning Criteria. The question is not whether relaxing a reliability requirement might be economically beneficial. The question that should be asked is "If you relax the reliability requirements of the planning criteria, will the system continue to provide an adequate level of reliability for the province?" La Capra did not even attempt to address how relaxing the reliance on imports to 20 percent or some other level would impact reliability for the province of Manitoba. Not respecting the reliability aspect of the energy criterion once again highlights La Capra's lack of experience with predominately hydro systems, and as previously explained, any comments La Capra has on the Energy Criterion of Manitoba Hydro's Generation Planning Criteria should treated with extreme caution.

[19] Transcript, April 7, 2014, page 6330, lines 3-16.

In planning for the reliability of the generation resources in a power system, there is a balance which must be struck between having sufficient resources under virtually all conditions and the net cost associated with having resources in excess of requirements. Reducing resources, including energy resources in an energy constrained predominately hydro system, is likely to have a negative effect on power system reliability. In its long term planning, Manitoba Hydro limits its reliance on imports to maintain reliability and thereby reduces the risk of unserved load and blackouts in Manitoba should an unusual operating event occur. La Capra did not acknowledge this negative effect on power system reliability when it proposed increasing Manitoba Hydro's reliance on imports from other power systems.

In the operating time horizon, imports are limited only by the physical capability of the transmission interconnection, and the available supply. This will allow Manitoba Hydro to manage energy contingencies or other unusual operating events as required.

As explained in Manitoba Hydro's Rebuttal Evidence[20], the Capacity Criterion has a minimum reserve against breakdown of plant and increase in demand above forecast of 12% of the Manitoba forecast peak demand. The Energy Criterion has no similar reserve margin. However, like the capacity calculations which have uncertainty due to forced generation outages ("breakdown of plant") and load forecast uncertainty ("increase in demand above forecast"), there is also uncertainty in the energy supply situation.

There are a number of sources of uncertainty in the dependable energy supply situation which were discussed at page 55 of Manitoba Hydro's Rebuttal Evidence. Further, two specific energy contingencies, increased energy demand due to an extremely cold winter or reduced energy availability due to an extended outage of a Manitoba thermal unit were discussed in the hearings in detail[21] The conclusion of this discussion highlights the fact that such energy contingencies are not explicitly considered in the energy criterion of the generation planning criteria:

> "MS. PATTI RAMAGE: So would you agree, then, that energy contingency events such as extreme winter or an extended outage of a thermal unit or, you know, a

[20] See Section 4.1.7 "Energy Contingencies are Likely" of the Manitoba Hydro Rebuttal Evidence, dated February 28, 2014.
[21] See Transcript for April 9, 2014, pages 6199-6204.

drought worse than the drought of record can occur, and none of those events are explicitly considered in Manitoba Hydro's energy criterion?

MR. DANIEL PEACO: I didn't -- it doesn't -- the criterion doesn't articulate that, no."[22]

MIPUG's expert witness, Mr. Patrick Bowman demonstrated an appreciation of the potentially disastrous impacts of tinkering with reliability based planning criteria in an attempt to optimize economics without consideration of whether the increase in risk is acceptable:

> "And I would strongly recommend that that criteria not be departed from lightly, if at all, because yielding on that criteria is the decision about the lights going out. It's a decision -- and not -- not for short periods of time. It's a decision about not having enough power for an entire winter."[23]

In summary, Manitoba Hydro's Generation Planning Criteria is the means by which Manitoba Hydro plans its system to provide reasonable assurance that load can be met over winter peaks, during droughts or other contingencies including generation outages, and recognizing that loads can be higher than forecast Both the energy criterion and capacity criterion in the Generation Planning Criteria must be satisfied in order to ensure a reliable supply of power adequate for the needs of the province of Manitoba.

The Generation Planning Criteria represents reliability criteria that must be met and cannot be treated as an economic consideration to be optimized. Manitoba Hydro's Generation Planning Criteria are reasonable, prudent, and consistent with both industry practice and the duties and responsibilities with which the Corporation is charged. All development plans prepared and analyzed by Manitoba Hydro meet the Generation Planning Criteria and thus provide an appropriate level of reliability for the Manitoba load.

5.3.5 Relationship between Energy Criteria, Need Determination, Production Costing and Operations

Manitoba Hydro long-term planning assumptions for import are applicable to the

[22] Transcript, April 9, 2014, page 6203, lines 23-25 and page 6204, lines 1-6.
[23] Transcript, May 2, 2014, page 10121, lines 6-21 and page 10122, lines 1-5.

determination of need for new resources and long-term modeling done in the context of resource planning. The long-term planning assumptions do not apply directly to the operational timeframe. The operation timeframe will have specific limitations and assumptions. These applications are generally as follows:

1. Determination of Need for New Resources

   The Supply and Demand Tables compare total system resources to total system demand to determine the need for new resources. The amount of imports which may be considered as dependable energy in total system supply is included in the Supply and Demand Tables. This amount of dependable imports is prescribed in Manitoba Hydro's Generation Planning Criteria.

2. Long Term Modeling (SPLASH) – Production Costing

   A primary objective of the SPLASH model is to generate production costs including net flow related revenue and costs. In the process of optimizing flow related revenues SPLASH optimizes the interaction with the market subject to transmission and market constraints.

   Imports in production costing are not defined by the Generation Planning Criteria. In production costing, the SPLASH model is simulating future operations. As a result the amount of imports assumed in the SPLASH model, in production costing, generally represents the amount of economic imports available to Manitoba Hydro. This amount is subject to the physical constraints of the system but is not limited, for example, by the 10% of Manitoba load limit or the off-peak limit found in the Generation Planning Criteria.

3. Operating Timeframe – Production Costing and Resource Optimization

Manitoba Hydro operates and dispatches its generation fleet and manages its export obligations on an ongoing and continuous basis in a manner that maximizes net revenue while maintaining a reliable and dependable supply of power. The amount of imports, in the operating time horizon, that can be accessed in the operation of the system is limited only by the physical capability of the transmission interconnections.

5.4 The Need for New Resources

Manitoba Hydro's Generation Planning Criteria provide the basis for determining when new resources are required to ensure an adequate supply of capacity and energy for Manitoba. Chapter 4 of the NFAT Business Case describes how Manitoba Hydro establishes the need for new supply resources in order to meet expected Manitoba load and firm export commitments. The Executive Summary of the NFAT submission on Page 10 states:

> "To determine Manitoba's electricity supply need, Manitoba Hydro regularly assesses domestic demand (load growth net of reductions resulting from DSM) and firm export commitments to arrive at total demand. Total demand is then compared to current supply. Total demand is currently projected to exceed existing supply beginning around 2023 even with no new export commitments. The need for new supply to meet Manitoba domestic load is the principal driver for the preferred development plan."

In determining the need for new resources, the limiting dependable energy criterion of the Generation Planning Criterion related to imports is the amount of energy that can be imported in the off-peak hours on firm transmission service.[24]

Increased levels of DSM will defer the need for new resources to serve Manitoba load. The results of the Supply and Demand tables in MH Exhibit #104-3 are summarized below and demonstrate the impact of the levels of DSM and new industrial load used in the DSM evaluation on the dates for the need for new resources.

[24] MIPUG/MH I-041c

Need for New Resources

	Dependable Energy
2012 Planning Assumptions	2022/23
2013 Planning Assumptions	2023/24
NFAT DSM 1	2028/29
NFAT DSM 2	2031/32
NFAT DSM 2 with increased pipeline load	2024/25
NFAT DSM 3	2033/34
NFAT DSM 3 with increased pipeline load	2029/30

5.4.1 Uncertainty in Load Growth and DSM Suggest Need to Protect Early ISD for Keeyask

It has been suggested that there is no justification for new generation related to the need to supply Manitoba load until late in the 2020's or beyond. In general the assumption is that with a combination of low load growth and continually expanding DSM there is an ability to forego new hydro generation for the early or mid 2020's and instead count on natural gas generation or some other short-lead time resource in the event that new generation is required earlier. While there is no absolute certainty that new generation is needed before the mid 2020's, there is inherent uncertainty in the need date and there is a high likelihood that new generation will be required in the mid 2020's (i.e. by or before 2025.) It would be imprudent for Manitoba Hydro to assume that no new generation is required until the late 2020s and not provide for new generation in an earlier time frame.

In effect, the 750 MW interconnection together with the advancement of Keeyask G. S. to serve long-term exports contracts reduces risk related to uncertainty in load growth and provides a form of insurance for higher load growth. In addition plans with Keeyask and the 750 MW interconnection provide economic benefits even if the higher load growth does not materialize. This is evidenced by plans with Keeyask, the interconnection and long-term export sales resulting in approximately $400 Million NPV benefits to Manitoba Hydro regardless of the level of DSM or even in a scenario of flat load growth not requiring any new generation[25]

From a supply planning perspective, committing to Keeyask for 2019 and a 750 MW interconnection together with long-term export sales has two distinct and major fundamental advantages which protect both load and supply and provide economic value:

1. When considering the risk of higher load growth, the system surplus under development plans with Keeyask, the 750 MW interconnection and long-term exports sales inherently provide a higher degree of assurance, reliability and energy security as opposed to counting on short lead time resource options such as natural gas or wind generation.

   As stated by MIPUG, and contrary to the suggestion of GAC in its final submission, large industrial loads may be committed by customers with relatively short lead time. Development plans with Keeyask, the 750 MW interconnection and long-term exports sales are better able to accommodate sudden higher domestic load growth as compared to shorter lead time resource options.

2. From a supply perspective, when compared to other development plans, plans with Keeyask, the interconnection and exports sales inherently provide a large amount of emergency reserve Load Carrying Capacity and Energy which provides additional insurance against major equipment failures, or more severe conditions than would be protected through resource planning.

5.4.2 High Likelihood of Needing New Generation in Early 2020's

Assuming the scenario with 2013 Load forecast plus 1700 GWh pipeline load minus level 2 DSM and assuming no new exports (as tabulated in Exhibit #104-3, pg 79), application of the dependable energy planning criteria would require new supply in 2024. If the one year deficit in 2024 were to be ignored, and the need date could be deferred to 2027, the beginning of persistent deficits.

However, there is uncertainty in the need date being 2027 because load growth is uncertain. For example, over the last ten years, the load forecasts for the load year 2023 has increased

[25] Tr. p. 9948, line 3

from one year to the next by up to 1292 GWh and decreased from one year to the next by 959 GWh.

The dependable energy supply and demand calculations utilize the expected load forecast. By using the expected load forecast, it is equally likely that actual load growth will be either higher or lower than forecast. As referenced in MH Rebuttal Evidence Exhibit #85-2, and as shown in the table below there is a material probability of the domestic load growth exceeding the dependable supply in the early 2020's. Given uncertainty in load growth, new supply could be required in 2023 with 41% probability or 2022 with 31% probability. These probabilities consider uncertainty in the underlying load growth and do not consider load variations due to extreme weather.

These probabilities of load exceeding dependable supply also do not take into account the uncertainty in DSM achievement. Similar to load growth, the amount of DSM actually achieved will be lower or higher than forecast and thus there is additional uncertainty in the amount of surplus energy and the date when new supply will be required.

MH Exhibit #188 provides the percentage of DSM achievement compared to the target for two years 2011 and 2012 for 26 US states. While the average of the 26 states approximately equals the target in 2011 and exceeds the target in 2012, there are many states in which the actual DSM falls short of the target. Maryland only achieved 50% of the 2011 target and New York only achieved 73% in 2012. While Manitoba Hydro is not aware of any studies determining the probabilities of long-term targets being achieved, an illustrative indication of such probabilities can be obtained from the 2011 and 2012 achievements for the 26 states. Applying the standard deviations calculated from the state statistics, there is a 10% probability that the incremental target one year into the future can be underachieved by 30%. While not a rigorous assessment, the state statistics and the illustrative probability calculation suggest that there is a risk the Manitoba Hydro aggressive plan to quadruple its DSM program may underachieve its target by a significant amount. This risk of DSM underachievement increases the likelihood of new supply being required in the early and mid 2020's.

Advancing Keeyask to 2019 takes advantage of the interconnection opportunity, is economic and provides risk management through protecting against potential increases in load growth and/or lower levels of DSM.

Table 1: Probability that Load Growth Greater than Supply When Considering Uncertainty in Economic Load Growth

5.5 Generation System Modelling

The Simulation Program for Long-term Analysis of System Hydraulics (SPLASH) is a computer-based generation system simulation model developed by Manitoba Hydro to support the long-term resource planning process. SPLASH simulates system operational, revenue and cost impacts of changes to generating resources, interconnections, energy contracts or key input assumptions such as reservoir operating limits or export prices.

As explained in Chapter 9 of the NFAT Business Case the forecast information associated with Manitoba domestic load, DSM, electricity export prices, natural gas prices, current and future carbon adders, and proposed export power sales is incorporated into the SPLASH model. The SPLASH model outputs include flow-related electricity export revenue and production costs such as fuel and variable operating and maintenance costs. The requirements of the Generation Planning Criteria are incorporated into the SPLASH model.

5.5.1 System Production Cost Based on the Average of 99 Flow Years

The SPLASH model is used to simulate the operation of the Manitoba Hydro system for the 35-year planning horizon (load years 2014/15 to 2047/48, inclusive). The 35 year planning horizon is simulated using 99 historic flow sequences, and the results are averaged to derive production costing data that is representative of all of the 99 flow years. The average values incorporate the effects of drought and flood flows. Specific analysis of the impact of drought is undertaken separately and focuses on specified historic periods of below average flow (e.g. 1988-1992).[26]

In Section 3.3.2 of the MPA report (page 34), the following statement is made, "Critically, Manitoba Hydro assumed average hydroelectric performance in every year throughout their models." MPA has misinterpreted how Manitoba Hydro utilizes the 99-year streamflow record to incorporate variability into the long term simulations.

Manitoba Hydro does not assume average hydro-electric performance in any year but rather Manitoba Hydro models the 35 year study period using 99 different flow sequences. The 35 year chronological flow sequences are taken from the 99 year historic record, allowing the last year of record to be followed by the first year (i.e. flows from 2010/11 are followed by flows from 1912/13). This allows 99 unique 35 year historic flow sequences to be modeled. Operating revenues and costs are determined for each of the 99 flow sequences for each year

[26] Manitoba Hydro Exhibit #85, Section 4.2.

of the forecast. The average of the 99 resulting annual revenues and costs is used to represent the economics of the forecast year, thus the economics from each year will reflect operations ranging from droughts to floods. The resulting averages for any given year will include some drought support costs, as well as significant opportunity export revenue associated with high system flows.

Therefore, the methodology employed by Manitoba Hydro does incorporate the variability inherent to the long-term flow data. The production-costing results are not based on system simulation using a (single) average flow condition.

5.5.2 Natural Gas Generation Representation in Splash is Accurate

While La Capra appears to have expertise in the modeling of thermal generation, the treatment of thermal generation within a predominantly hydro system presents different challenges. In Technical Appendix 3B La Capra questioned the SPLASH model results when comparing between the All Gas and All CCGT plans. In plotting the net opportunity exports against flow duration for the year prior to the need date, it was noted that there was a slight difference between the plan with a SCGT in 2022 and the plan with a CCGT in 2022. La Capra states "MH has provided no information that explains why there are differences in the resource mix for 2021, the year before the new resources are commissioned. The difference in net exports seen in the separation between the curves in this figure is small, but indicates inconsistency in modeling results"[27]. They further state "Since the resource mix and all other assumptions are the same between the plans in 2021, there is no explanation for the variation. The difference in gigawatt-hours is not large (approximately 250 GWh in hydro generation), but the fact that there is any difference at all could be a modeling error or change in prior year storage that we have not been able to reconcile with the material we have been provided"[28].

In an exchange with Board Counsel La Capra confirmed that intuitively there should be no difference in the resource mix the year before new resource are commissioned and they did not know why this was occurring. (CSI Tr. p. 849) Shortly thereafter, after being prompted by Manitoba Hydro Counsel that the reason for the different treatment was SPLASH's knowing a lower cost CCGT was coming into service in the next year allowed the assumption of additional economic exports in the current year, La Capra indicated that was a possibility they considered but weren't as familiar with SPLASH as they would have liked. (CSI Tr. p. 931) What is important to take from this exchange is that there was no

[27] LCA Technical Appendix 3B, page 3B-11, footnote 2.
[28] LCA Technical Appendix 3B, page 3B-13.

inconsistency in modeling results nor modeling error. The erroneous suggestion to this effect was in our view due to inexperience modeling a predominantly hydro system. The model results from the SPLASH model are consistent and accurate between the different development plans and scenario assumptions modeled for planning purposes.

Manitoba Hydro maintains that the model results from the SPLASH model are consistent and accurate between the different development plans and scenario assumptions modeled for planning purposes.

5.6 Resource Planning Methodology and Need – Conclusions

Manitoba Hydro is committed to pursuing all economic DSM. As part of fulfilling that commitment, Manitoba Hydro has undertaken an Integrated Resource Planning process which evaluates various combinations of supply-side and demand-side options to obtain an overall optimum combination and plan. The planning for DSM programs and integration with supply options will not stop with the NFAT analysis but will carry on in further stages (Manitoba Hydro Rebuttal, February 28, page 33). Manitoba Hydro will continue to evaluate both DSM and supply options and pursue the economic level of DSM.

The Generation Planning Criteria represents reliability criteria that must be met and cannot be treated as an economic consideration to be optimized. Manitoba Hydro's Generation Planning Criteria are reasonable, prudent, and consistent with both industry practice and the duties and responsibilities with which the Corporation is charged. All development plans prepared and analyzed by Manitoba Hydro meet the Generation Planning Criteria and thus provide an appropriate level of reliability for the Manitoba load.

Chapter 12 of the NFAT submission, total demand was projected to exceed existing supply beginning around 2023 even with no new export commitments. The need for new supply to meet Manitoba domestic load is the principal driver in the resource planning process. Increased levels of DSM defer the need for new resources to serve Manitoba load. For example under DSM Level 2 with Pipeline Load the need for need for new resource could be deferred until 2027.

However, there is uncertainty in the need date being 2027 because load growth is uncertain. For example, over the last ten years, the load forecasts for the load year 2023 has increased from one year to the next by up to 1292 GWh and decreased from one year to the next by 959 GWh. There is also a risk that Manitoba Hydro's aggressive plan to quadruple its DSM program may underachieve its target by a significant amount. This risk of DSM underachievement increases the likelihood of new supply being required in the early and mid 2020's.

In effect, the 750 MW interconnection together with the advancement of Keeyask Generating Station to serve long-term exports contracts provides a form of insurance for higher load growth and economic benefits even if the higher load growth does not materialize. Such plans are a means to reduce risks related to uncertainty in load growth. This is evidenced by Plans with Keeyask, the interconnection and long-term export sales resulting in approximately $400 Million NPV benefits to Manitoba Hydro regardless of the level of DSM or even in a scenario of flat load growth not requiring any new generation (Tr. p. 9948, line 3).

The results of the Economic Analysis are contained in Section 10.

6.0 Supply Options

As described in NFAT Business Case Chapter 7, Manitoba Hydro reviewed a range of resource technologies potentially suitable for utility-scale generation in Manitoba and, based on a high level screening, reduced this list to those technologies that were economically and realistically achievable within Manitoba over the detailed study period. This list includes DSM, large hydro, natural gas-fired generation, wind and imports. In order to evaluate the resource options, Manitoba Hydro made assumptions related to key characteristics including such factors as capital cost, operating and maintenance costs and efficiency/performance over time. These assumptions were informed by information from third party consultants and available industry information and are applicable for resource options developed in the Province of Manitoba.

6.1 Screening of Resource Technology Options

As described in NFAT Business Case Chapter 7, Manitoba Hydro undertook a thorough and structured screening of potential supply options. This screening process identified key attributes for resource options and, in particular, those specific attributes that would cause a resource option to be screened out of further analysis. The screening process resulted in the selection of DSM, Keeyask, Conawapa, natural gas-fired generation, a generic wind farm and imports for further consideration and evaluation. These resource options were considered technologically achievable, environmentally and socially acceptable, and cost competitive. Further, they had to be practical options that could be incorporated into development plans necessary to meet Manitoba's future needs.

La Capra, in Technical Appendix 3A, was critical of Manitoba Hydro's screening process. However, in La Capra's "Short-term View of Potential" as provided in response to PUB/LCA-048, their assessment paralleled Manitoba Hydro's screening results for all technologies considered except for biomass which La Capra considered as having a medium likelihood under their "Short-term View of Potential". In the same Information Request response, La Capra also provided a "Long-term View of Potential" which differed somewhat from their short-term view as La Capra considered both In-Lake Wind and Solar PV to have long-term potential.

Manitoba Hydro has acknowledged in the NFAT submission and during the NFAT process that changing circumstances over time may improve the attractiveness of certain resource options. However, it is Manitoba Hydro's position that, at this time, the uncertainty is significant enough to screen out these resource options from further analysis as it relates to development in Manitoba. From a utility scale perspective, biomass, solar and in-lake wind each have their own specific challenges at this time for development in Manitoba. These challenges are described in NFAT Business Case Chapter 7, and include environmental, technical and cost considerations. These factors render these resources options impractical as utility scale options for consideration for this NFAT development plan analysis.

6.2 Levelized Cost of Energy is only Appropriate as a High Level Screening Metric

As stated in Appendix 7.2 of the NFAT submission, "Levelized cost is a standard measure of the cost of constructing and operating a generating resource over its life. While it is a useful measure for comparing or screening of technologies, it should be noted that levelized cost does not indicate the value of the generation, but is a relative measure of the cost associated with a unit of energy." As a result, levelized cost of energy is most applicable when comparing like resource options or as a high level screening metric as was used in the screening analysis in the NFAT submission.

Caution must be exercised in comparing the levelized cost of wind to the levelized cost of the large hydroelectric projects, Keeyask and Conawapa Generating Stations, as provided by GAC's Mr. Wesley Stevens[29]. In Mr. Stevens' comparison, he observes that the levelized costs are similar but does not provide the context that hydro resource options are dispatchable, and wind resource options are non-dispatchable, intermittent resource options which do not provide the same product. To manage the intermittency and make the wind and hydro more comparable, the cost of a back-up generating resource, such as natural gas-fired generation, would have to be added to the wind costs, increasing the levelized cost of wind significantly.

6.3 Hydro Options

The evidence presented to the PUB clearly demonstrates that the methodology used by Manitoba Hydro to develop the Keeyask and Conawapa capital cost estimates is industry standard and best practice. Knight Piésold (KP), the independent expert consultant retained by the PUB, confirmed the approach and methodologies used by Manitoba Hydro for its capital cost, operation and maintenance estimates for Conawapa and Keeyask and stated they were "consistent with industry best practices" (page 1 of 4 January 13, 2014 KP report).

[29] GAC Exhibit #23, Slide 9

Further KP commented that the anticipated operation costs were within "industry norms and are well-documented."

The estimate for Keeyask now reflects the value of the signed General Civil Contract together with contingencies and management reserves that incorporate the lessons learned from earlier major infrastructure projects in Manitoba and North America. Although Conawapa is not as advanced as Keeyask, a similar process for developing the estimate for Conawapa has been utilized.

It is significant that at this stage of the Keeyask project, 80% of the contracts have been awarded or completed and these costs have been incorporated into the estimate. Manitoba Hydro has presented to the PUB both a project budget, which has been described as the control budget ($6.5B), together with a range of probable costs reflecting various contingencies set out in what has been described as the NFAT Low, Reference and High cases ($5.61B, $6.35B and$7.18B respectively). This range reflects the appropriate range of cost contingencies for the project and is in line with the risk of overrun estimated for other major infrastructure projects in North America.

6.3.1 The Most Current Information was used to Update the Estimate so as to Create the Highest Level of Precision Prior to Construction

Manitoba Hydro's methodology for developing capital cost estimates is outlined in the NFAT Business Case (Appendix 2.4 – Developing the Keeyask and Conawapa Capital Cost Estimates). A rigorous process was followed in establishing the point estimate; the risk-free, escalation-free (or bare) costs based on an initial set of assumptions and current market indicators. This is also referred to by KP in their report as the "overnight cost". There are no allowances for risk or uncertainty in the point estimate. These risks are included in the contingency analysis and incorporated into the control budget and further refined in the NFAT analysis.

The Keeyask and Conawapa GS capital cost estimates were developed following the Association for Advancement of Cost Engineering International ("AACEI") recommended practices for cost estimate development (page 1 of 27 of Appendix 2.4 - NFAT Business Case). KP described a high quality estimate as satisfying four characteristics: it is credible, well –documented, accurate, and comprehensive (January 17 Report Rev 0, pages 70-71) and found that Manitoba Hydro's estimates met all of these criteria.

Developing the point estimate started with the development of the project scope, compilation of all engineering design and a definition of all quantity information from the current design. The assumptions that form the basis of the point estimate for both Keeyask and Conawapa are derived from multiple sources, including: lessons learned from previous Manitoba Hydro generating station projects, information from current North American hydroelectric projects and other heavy civil projects and broadly-gathered market intelligence (page 2 of 27 of Appendix 2.4 – NFAT Business Case, August 2013 Appendix 2.4 Page 3 of 27). Direct cost items are those directly attributable to the construction of the primary asset under construction including but not limited to concrete costs, excavation costs and major equipment. These costs are developed in accordance with the design, quantities and contract packaging established by the project definition (January 17 Report Rev 0, page 7) and are subject to market factors at the time of the estimate. The assumed construction sequence and any specific work restrictions related to the site including seasonality of key work items are important factors to the cost estimate. Labour, material and equipment costs were all considered on the basis of industry experience, industry data and economic projections. These are contained and addressed within the GCC.

The lessons learned from Wuskwatim were applied to the Keeyask and Conawapa estimates and execution plans. Manitoba Hydro anticipates that the lessons learned will continue to improve the outcomes on its upcoming projects (page 36 and 37 of 51 of Chapter 15 of NFAT Business Case, and Pages 13 to 20 of 27 of Appendix 2.4 NFAT Business Case. Technical Conference presentations made on September 6, Slide 27). These lessons learned include:

- The benefits of an early start for the infrastructure project;
- An earlier completion for the detailed design engineering;
- Means to attract and retain project staff and labour;
- Engage the General Civil Contractor early by utilizing an Early Contractor Involvement project delivery strategy for the GCC;
- Project management practices; and
- Contingency planning.

These learnings are described in some detail below.

a) <u>The benefits of an early start for the supporting infrastructure</u> – The Keeyask Infrastructure Project ("KIP") was commenced early to reduce the risk to the construction schedule and provide additional benefits to the Aboriginal communities. KIP is on schedule and is nearing completion. In contrast, when the NFAT process for Wuskwatim was conducted and the subsequent regulatory decision to proceed was made, the project infrastructure had not yet begun.

b) Engineering – Manitoba Hydro is endeavouring to have an earlier completion date for the detailed design engineering. An earlier completion of design will allow for input from the contractors on how the constructability of the design can be improved upon, utilizing the experience and expertise of the contractor, thereby improving outcomes during construction (Technical Conference Tr. p. 380, lines 14-20).

c) Attract and retain project staff and labour – Issues with the attraction and retention of site labour became a major challenge on the Wuskwatim project and contributed to the increase in costs. Manitoba Hydro has taken steps to address this issue and has built mitigation measures into the Keeyask and Conawapa estimates (KP Evidence, Exhibit KP 3 -4, page 32/33 and Tr. p. 1464, lines 19-21). Labour challenges are being mitigated by having a premier camp, strategies developed jointly with the GCC during the Early Contractor Involvement phase, modifications to the Burntwood Nelson Agreement ("BNA") and the inclusion of a labour reserve to help address additional labour-related issues. In addition, Manitoba Hydro has also included additional costs in the recent update to the Keeyask capital cost estimate for hiring a third party construction management firm to oversee the on-site construction activities and mitigate this risk.

d) Early Contractor Involvement and project delivery strategy for GCC – Manitoba Hydro is using an Early Contractor Involvement delivery strategy for the General Civil Contract. Multiple contracts such as the Electrical and Mechanical works will also be bundled under the GCC to help reduce potential interface and scheduling issues (page 30 of 51 of Chapter 15 of the NFAT Business Case). KP has supported this decision as "a very sound move" (Tr. p. 6735, line 16).

Contract tendering on Keeyask has been a mixture of methods tailored to the individual contracts. The decision to award the GCC using a target price contract reflects Manitoba Hydro's experience with Wuskwatim and that of the industry in recent years. KP has endorsed this overall approach as appropriate in principle (Tr. p. 6733, lines 4-11). KP commented that the overall delivery strategy is to transfer risk away from the contractor in order to better understand and share the risks and obtain a better contract price as a result (page 2 of 4 of KP report, January 17, 2014, Revision 0). Mr. Robertson who gave evidence on behalf of KP, stated that their recent experience has led them to conclude that it is more appropriate and affordable to share the risks between the owner and contractor and therefore KP affirmed Manitoba Hydro's decision to proceed with a target price contract (page 25 of 73, KP report, January 17, 2014, Revision 0. See also Tr. p. 6878, lines 2-23). This is one of the key reasons why Manitoba Hydro used this form of contract. For the Keeyask Project, Early Contractor Involvement was implemented with the selection of a general civil contractor two years before construction of the principle structures including powerhouse, spillway, dams and dykes is scheduled to proceed. The main objective served by engaging the contractor early is that it allows for the contractor's construction knowledge to be incorporated into the final design and provides the contractor an opportunity to plan their work, secure their staff and the necessary labour, and form alliances with Manitoba suppliers and sub-contractors well before the actual site work begins (NFAT Exhibit KP 3 (presentation) page 14 and Tr. p. 6733, lines 15-25).

e) ***Project management practices*** – KP supports Manitoba Hydro's approach to the management of the GCC and stated that the Early Contractor Involvement process reflected a genuine and appropriate opportunity for Manitoba Hydro to optimize and to bring as much certainty to the contract as possible (KP supplemental report, April 8, 2014, Revision 0, page II of III). The approach to tendering the contract was deemed to be comprehensive, well-documented and applied and the timing of the tendering appeared to be on track (KP Supplemental Report, April 8, 2014, Revision 0, page 1 of 3).

Manitoba Hydro has developed methods to identify and monitor risks to the project as well as strategies to manage and mitigate these risks during construction. The risks will be managed through the development of a risk registry which has been reviewed and revised with the assistance and input of external experts and with the insight gained from Wuskwatim, KIP and other projects. KP has indicated, "The approach to construction risk management is industry standard and consistent with best practices with specific roles and responsibilities associated with risk management in the overall management process. As far as can be seen the risk management strategy is well set up and is being monitored and acted upon appropriately." (KP Supplemental Report, April 8, 2014, Revision 0, I of III).

f) ***Contingencies*** – Manitoba Hydro developed contingencies using the AACEI recognized parametric and expected valuing method (see page 7 of 27 of Appendix 2.4 – NFAT Business Case). The inclusion of the contingency at a P50 level addressed the majority of the uncertainty associated with the point estimate. Other key items are addressed through the use of a management reserve. Manitoba Hydro worked with Validation Estimating, an independent expert, to establish its contingency reserves and ensure that internal optimism from the project team did not bias the process. KP stated that Manitoba Hydro has examined the causes that lead to increased capital costs and made "a realistic appreciation of current trends in their cost estimating process" (III of IV of KP report, January 17, 2014, Revision 0). While there will always be challenges associated with determining the appropriate range of contingency for projects of the scale of Keeyask, the uncertainty is usually associated with the degree of systemic risk in the project and is naturally greater earlier on in the project development. The PUB has been provided with evidence that for Keeyask 80% of the contracts are now awarded. As a result, much of the uncertainty and systemic risk has been addressed.

KP has been clear in its reports and testimony that Manitoba Hydro has employed best practices/industry standard practices in the preparation of the estimates with respect to *both* Keeyask and Conawapa. Manitoba Hydro submits that the PUB can have confidence in the estimates provided.

6.3.2. Keeyask Estimate

The Keeyask estimate captures all current information and is based on the fact that 80% of the contracts have been awarded to date.

On March 10th, Manitoba Hydro awarded the General Civil contract (GCC) to BBE Hydro Constructors Limited Partnership consisting of Bechtel Canada Co., Barnard Construction of Canada Ltd. and EllisDon Civil Ltd. for the amount of $1.4B. The GCC represents the single biggest contract on the Keeyask Project. The decision to award the GCC to BBE was made after a thorough and complete analysis of the four bidders (proponents) proposals, all of whom had been prequalified for their knowledge, expertise and capacity to deliver a project of this magnitude. Bechtel was also the primary lead of the general civil contractor consortium on the Limestone project, which came in on schedule and under budget. The contract award price was slightly higher than the estimate. This increase contributed to the $300M (or 5%) increase to the control budget that was presented to the Panel on March 10th.

Keeyask

To choose a contractor, Manitoba Hydro first utilized an RFP process in which it prequalified four proponents and retained the services of an independent estimator to produce a baseline bid using the materials and information provided to the prequalified proponents. The proponents were provided with detailed project specifications and provided the opportunity to meet with and discuss the issues with Manitoba Hydro following which they provided comprehensive bids. Manitoba Hydro then carefully and thoroughly reviewed those bids and measured them against the Manitoba Hydro Engineer's Estimate, which had been developed with an engineering consulting firm and against the independent estimate (Tr. p. 6877, lines 1-6).

KP stated in both its reports and in its oral evidence that Manitoba Hydro staff were professionals and had expertise in estimating, consulted industry experts in their deliberations, and were open and forthcoming with KP in assisting KP in their inquiries.

KP satisfied itself as to the reasonableness of Manitoba Hydro's estimates by undertaking a review of the direct estimate tables and found the indicated quantities and unit rates to be reasonable (page 14 of 73 of KP report, January 17, 2014, Revision 0). KP also reviewed Manitoba Hydro's material quantities and applied typical unit prices to produce a high level estimate. The estimate KP was able to produce had similar values to the Keeyask and Conawapa estimates using a different methodology. As noted by KP, this "affords some comfort that the cost estimate is in the correct ballpark" (page 18 and 19 of 73 of KP report, January 17, 2014, Revision 0). KP stated that Manitoba Hydro had been diligent in their internal comparisons between the four GCC tenders, their Engineer's Estimate and the independent estimate (KP Supplemental Report, April 8, 2014, Revision 0, page 21 of 26 and Tr. p. 6757, lines 4-7).

The P50 base estimate includes some measures and contingency to deal with the degree of labour availability and productivity issues (page 15 of 27 of Appendix 2.4 – NFAT Business Case). The escalation reserve is intended to cover additional costs over CPI.

KP looked at these issues and noted that the labour reserve appeared to be in the correct order of magnitude (page 30 of 73 of KP report, January 17, 2014, Revision 0). KP also noted that Manitoba Hydro was justified in increasing the direct and indirect costs associated with labour to address productivity and shortages, competition with other large civil projects, and the remote location of the project site (Page III of IV of KP report, January 17, 2014, Revision 0).

KP concluded that it was apparent that new procedures set up for Keeyask and Conawapa were the direct result of the lessons learned from Wuskwatim and reflected "genuine Manitoba Hydro concern to manage the whole process better". They stated that the risk management strategy was well set up and was being followed and concluded that at this stage the most significant technical risks have been addressed, a significant financial risk has been removed with the awarding of the GCC (Exhibit KP 3, pages 46-47 and Tr. p. 6746, lines 2-12).

In its presentation to the Panel on April 14th, and in their report dated April 8, 2014 page II of III, KP identified key risks to be addressed in the contingencies, and which they had identified from their review of the Validation Estimating report produced for Manitoba Hydro. The perceived concerns associated with those risks were addressed in Mr. Bowen's evidence and in the cross examination of KP as follows:

- Resource challenges;
- Systemic risks associated with Manitoba Hydro's maturing system;
- Schedule risks associated with MH's maturing system;
- Adverse labour productivity (addressed through labour reserve);
- Risks that could cause a year of delay: Stage 1 Coffer Dam delay, extreme weather, etc.

[redacted]

[redacted]

Like many organizations planning to construct major capital assets, Manitoba Hydro made the decision to plan for contingency at a P50 level. Using a P50 level in the Control Budget ensures that the budget is adequate, realistic and achievable. Manitoba Hydro views this as the appropriate balance between establishing a control budget that is aggressive enough to help promote a lower ultimate cost outcome and realistic enough to complete the project within budget. The control budget will set a benchmark to measure project performance. The concern being that if contingency was set too high, there may be a tendency to spend up to that value while if the budget is set too low, the project may exceed the budget. Others support this as a reasonable concern (Tr. p. 6890, lines 2-25).

Manitoba Hydro is at a stage in the project development where the technical risks have been addressed and mitigated. They have hired a suitable, reputable and experienced company for the GCC. The remaining construction risks are now associated with the contractor performance in terms of its quality, cost and schedule. Portions of the overall contingency had been allocated to the individual contracts to provide allowances to cover these risks (KP Supplemental Report, April 8, 2014, Revision 0, I of III).

The overall expected in service cost for Keeyask has been prepared by Manitoba Hydro with as much completeness as can be reasonably expected at this stage. The current estimate is no longer bottom-up as was the estimate created in 2009. It is now a blended estimate that includes the awarded contracts (KP Supplemental Report, April 8, 2014, Revision 0, III of III). It is also of significance to note that Manitoba Hydro retained Validation Estimating, an external resource with expertise in estimating and establishing contingency reserves. KP relied on the Validation Estimating statement that "the recent incorporation of the GCC contract costs reduced the uncertainty in respect of competiveness of the estimate". KP then commented that the reassessment included a reappraisal of their contingency and management reserves and further stated that KP has no better data to offer or better estimate of the expected in service cost for Keeyask. (KP Supplemental Report, April 8, 2014, Revision 0, page 23 of 26).

6.3.3 How Much Could Keeyask Cost?

In order to be fully informed of the potential risks associated with the capital cost estimates of the Preferred Development Plan as compared to alternatives, it is appropriate to consider the potential risk of a project exceeding the capital cost budget. Manitoba Hydro has, through the NFAT Low, Reference and High scenarios, identified a range of probable costs that may occur for the Keeyask GSP, and has incorporated those ranges into its economic and financial analysis of the various plans. These scenarios use contingency values of P10, P50 and P90 respectively.

The NFAT High scenario (P90) was used to help establish the appropriate and real upper limit of costs. As noted in the evidence before the PUB, the use of a P90 is debatable. As noted in Manitoba Hydro's Rebuttal Evidence, Exhibit #85-2, in an effort to bring more clarity to the issue, KP and Manitoba Hydro met with Mr. John Hollmann from Validation Estimating via teleconference on April 24th, after KP had presented their evidence to the Panel. Hollmann advised that while a P90 tends to be used for a high business case scenario, it is not appropriate to plan for anything higher than a P90 as the tails of the contingency curve tend to drag out and are not generally used for quantitative analysis.

With 80% of the contracts having been awarded, the Keeyask project is more solidly defined than at any point in the past and is more defined and advanced than with any other project in any previous NFAT. The award of the GCC, a major component of the control budget is known, which can only enhance the confidence, and we submit should increase the comfort level of the Board in considering the costs of this project. (KP Supplemental Report, April 8, 2014, Revision 0, page 1 of 26).

Much has been made about the increase to the capital costs of Wuskwatim as the project progressed and of the tendency for major infrastructure project costs to increase. Manitoba Hydro has identified the reasons for the Wuskwatim cost increases and has appropriately accounted for them in the estimates of Keeyask. In addition to identifying *why* the cost increases occurred, it is important to also identify *when* they occurred. The capital costs for the Wuskwatim project increased from $988M in CEF-03 to $1.771B in CEF-12 (PUB/MH I-038). Included in this increase is a deferral in the Wuskwatim in-service date by three years as well as other increases incurred as the project increased in definition. It is therefore not appropriate to use Wuskwatim as a reference or criticism of Manitoba Hydro's ability to estimate, or to infer that the costs of Keeyask are at risk of similar increases. On Keeyask, the supporting infrastructure is being developed through KIP and is essentially complete, providing Manitoba Hydro an additional level of cost certainty. The GCC has been awarded. Calculating the cost increases on Wuskwatim from a similar point in the project until project completion would yield an increase of approximately 10% (Tr. p. 1459, lines 7-15). If this same increase were to occur with Keeyask, Manitoba Hydro would utilize the P50 contingency as well as the labour and escalation reserves and remain within the control budget of $6.5B. Manitoba Hydro has learned from the experience with Wuskwatim and has confidence that the Keeyask project has an appropriate control budget and includes sufficient reserves to offset specific increases in capital costs such as those that occurred during Wuskwatim.

Industry has recently recognized that the tendency for major infrastructure project costs to increase is predominant in the early definition phases and is largely a systemic risk. One of the reasons the Keeyask cost estimate has increased over the past few years is because Manitoba Hydro has captured this systemic risk in its estimate.

KP was complimentary of Manitoba Hydro's openness to learning from its experience, the expertise of its staff and their willingness to consult. Manitoba Hydro therefore submits the rigorous review engaged in first by Manitoba Hydro and then by the PUB through the independent expert consultant should provide the PUB with confidence that Manitoba Hydro has established an appropriate control budget and the range of costs used in the NFAT are appropriate.

Manitoba Hydro, the PUB and its independent expert KP, have all had the benefit reviewing both Manitoba Hydro's estimating process and the outcome of that preparation. With the recent updates to the Keeyask and Conawapa capital cost estimates presented at the NFAT hearings, the Panel has access to the most current and accurate information possible at this time. While Manitoba Hydro's initial analysis originally led to estimates that were lower than the ultimate contract price for the Keeyask GCC, it is important to recall that KP's initial report (January 18, 2014) supported the process MH had utilized to arrive at those estimates. Despite the increase to the expected in-service cost of Keeyask, there is greater certainty in the estimate with the award of the GCC (Tr. p. 6761, lines 3-4).

There has been concern expressed by some parties, and by the Board itself as to the possibility of the costs of Keeyask continuing to increase. Manitoba Hydro would remind the Board of the comments of Dr. Borison who cautioned against assuming that because costs have recently increased that they will continue to do so. At transcript page 1651 and following, Dr. Borison discussed the concept of anchoring, and said:

> "And there certainly have been changes, no doubt about that, and particularly in capital costs.
>
> But there is -- one of the number-one biasses that people have in their judgment is what's called anchoring, which you tend to really, really remember what happened today, but you -- you don't realize, well, maybe that's -- maybe the future will be different from that. And so there is a tendency to almost jerk around, like if you're sailing, to basically go one way, and then the other way when things change. You have to be careful about that. It doesn't mean you don't want to use the latest information. But you have to be careful you don't over weight what you just found out, like gas prices just went down or they just went -- went up. So not -- not contradicting the idea of updating and being careful about that, but you have to be careful, let's say, not

to over adjust your forecast for the year 2030 based on what happened last week..."

The PUB should take comfort from the fact that Manitoba Hydro has incorporated all current information into the estimate, made the required adjustments to the estimate and that KP has thoroughly reviewed Manitoba Hydro's estimating process and confirmed the methods are industry standard. The output of Manitoba Hydro's industry-standard estimating practices is the $6.5 billion capital cost estimate for the Keeyask Generating Station, which KP confirms is a sensible, best estimate for the cost of the project (Tr. p. 6761, lines 5-10).

6.4 Wind

6.4.1 Manitoba Hydro's Costs Estimates for Wind Projects in Manitoba are Reasonable

Manitoba Hydro has based the assumption for the cost of building wind in Manitoba on a Manitoba specific estimate provided by the independent consult GL Garrad Hassan and has verified this estimate using applicable industry information.

In the report [30] provided by GL Garrad Hassan a Manitoba specific capital cost estimate [redacted] was developed for a utility scale, 150 MW generic wind farm built in southern Manitoba. In order to assess the validity of this cost estimate, the findings of the report were compared to costs for on-shore wind projects from another confidential source, the EPRI 2012 Renewable Energy Technology Guide, published in 2013 by the Electric Power Research Institute. The EPRI report provided an average installed cost for wind generation [redacted]

La Capra, Knight Piésold, and the Green Action Centre and its consultant Power Advisory have argued that Manitoba Hydro's cost estimate for a wind project built in Manitoba is too high[31].

The main source for the capital cost of wind used by La Capra, Knight Piésold and GAC[32] to

[30] Confidential "CAPEX & OPEX Estimate for a Generic Wind Farm in the Province of Manitoba" prepared for Manitoba Hydro by GL Garrad Hassan dated September 7, 2011.
[31] La Capra Technical Appendix 2, Page 2-20; La Capra Initial Expert Analysis Report, page LCA-14; LCA-6, La Capra Technical Appendix 3A, Page 3A-32; Knight Piésold Independent Expert Consultant Report, page 49; Green Action Centre Evidence on Fuel Switching, DSM and Wind, page 4-14.
[32] La Capra Technical Appendix 2, Page 2-9; Knight Piésold Independent Expert Consultant Report, page 49; Green Action Centre Evidence on Fuel Switching, DSM and Wind, page 4-3.

support their arguments regarding Manitoba Hydro's alleged high capital costs for wind is the US Department of Energy (DoE) report, "2012 Wind Technology Market Report" (2012 DoE report) which presents an average cost of $1,760/kW for wind projects constructed in the "Interior" Region of the USA in 2012[33].

Manitoba Hydro contends that the average project costs of approximately $1,760/kW (2012$) for wind projects constructed in the "Interior" Region of the USA in 2012 is not representative of the cost to develop wind generation in Manitoba. Mr. Peaco acknowledged that the Interior Region included forty-two (42) wind projects installed in 2012 from North Dakota to Texas with a range of capital costs from $1,400 to $2,400 per kilowatt and recognized that these costs were based largely on projects from southern states such as Texas. He also acknowledged that while the cost reported for the Interior US may be most representative, "it's not the Manitoba data". [34] Manitoba Hydro provided evidence based on construction industry data that costs to build are generally higher in Manitoba than in North Dakota". (MH Exhibit #85 page 72)

Power Advisory's Mr. Stevens initially recommended[35] using the $1760/kW (2012$) for the cost of wind generation and then in his direct evidence[36]changed this recommendation to the use of $1940/kW (2012$). As a basis for using the higher estimate he stated "I can't say with confidence that I understand why costs are lower in the Midwest. So we thought it was certainly more conservative to use the average for all of the US rather than the -- the average specifically for -- for the Midwest."[37] This further illustrates that caution must be applied when comparing construction costs in Manitoba to US industry data and that Manitoba Hydro's reference case estimate of capital costs for a wind project without transmission costs of $2,100/kW (in 2012$) or $2,200/kW (in 2014$) is reasonable and appropriate.

During cross examination by Manitoba Hydro Mr. Stevens indicated that he would have preferred to rely upon a study of wind costs specifically adjusted for Manitoba:

> MR. WESLEY STEVENS: And I'd like to add that. What I would love to see or have seen is a reasonable cost—a reasonable estimate for a North American wide cost, and then an adjustment factor for—Manitoba; why-how is Manitoba different from the North America as a whole. That would have been a very reasonable approach.

[35] Resource Insights/Power Advisory Report, page 4-3.
[36] GAC Exhibit 23, Wesley Stevens of Power Advisory direct evidence, Slide 4.
[37] Transcript page 9668.

> PATTI RAMAGE: So if I understand you correctly, your preferred approach would be one that's taken North American-wide costs and adjusted for Manitoba, something that was specifically done?
>
> MR. WESLEY STEVENS: Yes. Starting out with a reasonable number for the North American-wide cost. (Tr. p. 9831, line 20)

Manitoba did better than the approach described by Mr. Stevens. In developing its capital cost estimates Manitoba Hydro retained third party consultants to develop specific estimates for Manitoba based on actual costs provided by actual turbine manufacturers – not just a survey of costs adjusted for Manitoba. The PUB and IECs have access to the Garrad Hassan Report that was relied upon for this purpose.

6.4.2 Manitoba Hydro's Assumptions for Future Wind Cost and Capacity Factors are Appropriate

Manitoba Hydro maintains that using a constant capital cost, with no real escalation, and a constant capacity factor for future wind projects, are appropriate assumptions for the economic comparison of development plans with wind resource options in the NFAT submission.

La Capra, Knight Piésold, and GAC's witness Mr. Stephens, predict a declining trend in the cost of on-shore wind projects[38]. The primary source that all three of these consultants used for this assumption is a report produced by National Research and Engineering Laboratory (NREL). While the report provides perspectives on the future costs and performance of wind technologies, the report also provides the following conclusion[39] characterizing the state of the current knowledge and providing context to the information contained within the report:

> "The technology is now at a point where an optimal cost of onshore wind energy may result from little or no further capital cost reductions (and perhaps even modest capital cost increases), but continued performance improvements. In this environment, it is possible to see capital costs remain relatively flat—with possible modest reductions or increases, depending on local market conditions—into the future and to see performance increases as

[38] LCA Technical Appendix 2 Generation Alternatives, Pages 2-10 to 2-11; Knight Piésold Independent Expert Consultant Report, Page 48; Green Action Centre Evidence on Fuel Switching, DSM and Wind, page 4-4 to 4-5;GAC Exhibit 23, Wesley Stevens of Power Advisory direct evidence, Slide 7.
[39] NREL, The Past and Future Cost of Wind, IEA Task 26, May 2012, Conclusions and Future Work, Page viii

the primary target of original equipment manufacturers (OEMs)."

As evidenced by the NREL conclusion, whether the capital cost of wind will decline in the future is unknown and uncertain, particularly when factoring in potential cost increases required to achieve improved performance (higher capacity factor). Caution associated with assuming declining capital costs and increased performance was noted by GACs expert Mr. Stevens of Power Advisory where he stated "To assume both declining capital costs and increasing capacity factors runs the risk of double counting"[40]. La Capra has taken liberties in application of the information contained within the NREL report to wind projects in Manitoba, assuming both a significant continuing decline in capital cost in the order of 1% per year until 2030 and a higher capacity factor (43%)[41]. Manitoba Hydro finds this position to be optimistic and hopeful given the inherent uncertainty in the future costs of wind development.

Based on current experience with the wind projects in operation in Manitoba, Manitoba Hydro has assumed a capacity factor of 40%[42]. As demonstrated in MH Exhibit #85[43], meteorological monitoring and analysis of seven (7) sites in southern and central Manitoba, shows that potential capacity factors ranged from a high of 38.2% down to a low of 22.8%. A second study, specifically targeting 7 additional sites in the St. Leon/Darlingford area, shows potential capacity factors ranging from a high of 37.4% down to a low of 29.2%. Based on this information, Manitoba Hydro expects that new wind projects built in Manitoba will be developed on sites which will have progressively less ideal wind resources, which in turn will reduce performance and related capacity factors. This position was supported by Mr. Stevens who confirmed that, holding all else constant, one would expect to see a drop in the capacity factors as better sites are developed[44].

Despite the reality of declining site conditions, Manitoba Hydro assumed in the NFAT submission that technological improvements will achieve incrementally higher capacity factors at future sites. These competing considerations effectively result in a constant system capacity factor for wind projects into the future. Manitoba Hydro also assumes that these technological improvements will come at a cost and that will approximately offset potential future capital cost reductions. The net effect is a constant capital cost and a constant capacity factor for wind projects into the future, which are the assumptions that have been used in the NFAT submission.

6.4.3 Wind Integration Costs Are Appropriate For the Manitoba Hydro System

GACs Power Advisory raised issues with regard to the conservative nature of Manitoba Hydro's integration cost assumptions for screening wind generation[45]. Manitoba Hydro notes that wind generation was not rejected as a result of the screening exercise for resource options – and accepting Power Advisory's recommendation would not change the NFAT analysis or conclusions.

With respect to Manitoba Hydro's economic analysis, the wind integration costs were scaled based on the costs provided in Appendix 9.3: $4.22/MWh for 500 MW of wind generation and $4.99/MWh for 1000 MW of wind generation (2005 US dollars). Actual wind integration costs used in any one particular year are impacted by actual levels of wind development and changing export prices over the detailed study period. Manitoba Hydro's wind integration costs were explained at page 23 of Appendix 9.3 of the NFAT Application, and further clarified in Manitoba Hydro Exhibit #136. Manitoba Hydro notes that according to CAC Exhibit #45, BC Hydro used wind integration costs of $10/MWh in the base case for their November 2013 Integrated Resource Plan filing, and performed additional sensitivities with wind integration cost of $5/MWh and $15/MWh. Manitoba Hydro's wind integration costs are based on Manitoba Hydro specific system studies and are reasonable.

6.5 Solar Photovoltaic (PV) Appropriately Screened Out In the NFAT Analysis

In Chapter 7 of the NFAT submission, solar PV resource options were considered for evaluation as utility scale options. Manitoba Hydro also recognizes that there is potential over the longer term it may become attractive for customers to install solar generation as a form of self generation. The potential and timing of the adoption of solar PV for self generation Manitoba is discussed in Section 4.3, DSM (grid parity).

In NFAT Business Case Chapter 7, Manitoba Hydro provided two key reasons for screening out utility scale solar photovoltaic generation in the development plan analysis in the NFAT submission: cost and the significant intermittency of the solar resource[46]. In their evidence[47], La Capra criticized Manitoba Hydro for screening out solar PV.

Manitoba Hydro acknowledges that solar photovoltaic is an established technology with

[45] GAC Exhibit #23, Green Action Centre Evidence on Wind, page 8.
[46] NFAT Business Case, Chapter 7, page 18.
[47] La Capra Technical Appendix 3A, Page 3A-17.

significant opportunity for potential technological improvement and that a good-quality potential solar resource exists within southern Manitoba. Manitoba Hydro agrees that these attributes may combine to make solar photovoltaic alternatives more competitive in the future[48].

In its Rebuttal Evidence Manitoba Hydro stated that "Due to the intermittent nature of solar PV, significant instantaneous variability in generation must be either managed with backup generation or with a type of storage technology, increasing the capital cost significantly and/or incurring system integration costs."[49] The additional costs associated with managing intermittency were not recognized by La Capra.

Given uncertainty in the future cost of solar PV as well as the additional costs associated with managing intermittency, costs which were not specifically included in the calculation of Levelized Cost of Energy, Manitoba Hydro maintains that solar PV was appropriately screened out of further analysis.

Knight Piésold concurred with Manitoba Hydro's conclusions on solar PV capital costs stating that "In our view, MH's capital costs are in-line with the range of reported costs for recent Solar PV projects."[50] They further stated that "KP agrees with MH that solar PV generation is not cost-competitive in Manitoba in 2014."[51]

In cross examination, Mr. Dunsky recognized the need to include additional cost to manage intermittency of the solar PV resource options when he said "Absolutely. There's an additional cost for capacity. But absolutely on storage, yeah, you need to add storage costs to do an apples-to-apples comparison" [52]

As described in its response to MH/LCA I-288, Manitoba Hydro acknowledges that solar PV is one of the resource technologies which is experiencing a downward trend in cost and which has potential for additional decline. Manitoba Hydro notes that additional decline in the price of solar PV installations will also require a reduction in the balance of system cost not associated with the solar PV modules themselves (planning/permitting processes, civil and electrical works and related labour). Current experience in Manitoba is that civil and electrical works and related labour costs have been increasing not decreasing.

[52] Transcript pages 8133-8134.

Further, Manitoba Hydro is of the view that the current competitive position of solar generation remains heavily dependent upon North American governments promoting solar generation through feed-in-tariffs, tax credits, renewable portfolio standards, and climate change legislation.[53] Ms. Flynn provided additional context with respect to recent solar development in the US which is concentrated in California where high electricity rates and the State's renewable portfolio standard are driving development.[54]

Manitoba Hydro's caution regarding the guarantee of a perpetual decline in solar PV pricing is echoed by MIPUGs Mr. Patrick Bowman where in a discussion of solar pricing trends he stated "At this point, I'm not sure it's as rosy as some people present, but it's certainly got some uncertainty involved in it."[55]

6.6 Natural Gas-Fired Generation Assumptions are Reasonable

The natural gas-fired generating resource options and costs used in the NFAT submission were based on recommendations for technology options suitable for development in Manitoba provided by a third party consultant, Gryphon International Engineering Services Inc.

Knight Piésold supported Manitoba Hydro's capital cost assumptions for natural gas-fired generation when they stated "Use of the natural gas capital cost … for the CCGT and … for the industrial style SCGT is appropriate"[56]

With respect to Manitoba Hydro's assessment of natural gas-fired generation, La Capra, in their Initial Expert Analysis Report page 14, stated "MH's analysis does not factor in any anticipated improvements in efficiency over time in the future in its planning."

Manitoba Hydro acknowledged in Chapter 7 of the NFAT Business Case that innovation in the field of combustion turbines will lead to more efficient machines that operate at lower heat rates. While continued improvements in turbine technology can be expected, Manitoba Hydro made the decision to leave turbine efficiencies constant over time to recognize the effect of off-setting factors. The expectation of technological improvement is offset by degradation in performance over time and by operational inefficiencies related to units operating at lower than optimum efficiencies at times. In its analysis Manitoba Hydro does

not assume either technological improvements or reductions in performance and considers this assumption to be reasonable for use in the NFAT analysis.[57]

6.7 Brandon Unit 5 Retirement Assumptions Are Appropriate

For the purposes of resource planning, Manitoba Hydro assumes that the sole remaining coal-fired generating unit, Brandon Unit 5 is only available until December 31, 2019. This unit cannot be counted on beyond this date primarily due to the uncertainty related to its remaining physical life; and the potential to maintain the current conditions of its operating license.

In 2006, Manitoba Hydro filed a plan with Manitoba Conservation for their Environment Act Licence Review process to operate Brandon Unit 5 until approximately 2020. The Province has not concluded its license review. If the plan were to be amended to include operation beyond 2019 it is uncertain that the Provincial government would support extended operation given its perspectives related to a fossil free future as illustrated by the Clean Energy Strategy. If the Province of Manitoba did not explicitly preclude operation beyond December 31, 2019, additional environmental controls could be imposed. Given the age (50 years in 2019), it's already very restricted operation and its small size, the costs of additional environmental controls would not likely be justifiable. In addition, while the federal coal regulations allow for standby operation until 2030, it remains unclear if this includes a workable provision for protracted operation during drought (a primary role of this unit).

La Capra's Brandon 5 Retirement Approach is Flawed

La Capra Associates has asserted that Manitoba Hydro makes several conservative assumptions, including the retirement date of Brandon Unit 5, which could mitigate the need for new capacity.[58] They further indicate that keeping the Brandon coal unit as a dependable energy source extends the energy year of need by five years under 2013 assumptions[59]. The evidence presented to support the La Capra argument fails to recognize the circumstances of this unit presented in the original NFAT submission and subsequent interrogatories. La Capra chooses to simply conclude "MH has provided no evidence that it must remove Brandon from service in 2019, and could keep the unit in service for capacity purposes"[60] and more

[57] Manitoba Hydro Exhibit 85, pages 75-76
[58] La Capra Associates, Initial Report, page 5.
[59] La Capra Associates, *Technical Appendix 01 – Resource Planning*, pages 1-39.
[60] La Capra Associates, *Technical Appendix 01 – Resource Planning*, pages 1-29.

generally that "MH's needs analysis uses the most conservative assumptions on resource availability. These assumptions include retiring the Brandon Unit #5 before necessary,…"[61].

The 2012/13 Power Resource Plan filed with the Board outlines the Brandon Unit 5 retirement assumptions. Brandon Unit 5 is governed by Manitoba's *Climate Change and Emissions Reductions Act* and its subsequent MR 186/2009, the Coal-Fired Emergency Operations Regulation which restricted coal-fired operation to "…support emergency operations"[62].

Brandon Unit 5 will also be regulated under Environment Canada's Reduction of Carbon Dioxide Emissions from Coal-fired Generation of Electricity Regulation. As provided in evidence[63], these coal regulations will come into effect July 1, 2015 and will place additional constraints on Brandon Unit 5 after December 31, 2019[63]. The regulations require that coal-fired units that cannot meet a performance standard will have to shut down at the end of their useful life (defined as 50 years from the date of commissioning). Brandon Unit 5 was commissioned in 1969 and will reach its 50 year of service in 2019. This is considered the full useful life of a coal generating unit under the federal coal regulation. While the federal regulation makes provision for emergency standby operation beyond 2019 until 2030, prolonged operation during drought would require the Minister responsible for the Emergency Measures Act of Manitoba to declare a state of emergency[64]. It remains unclear if this provides a workable provision for protracted operation during drought which is a primary role of this unit.

As discussed previously, given their perspectives related to a fossil fuel free future, it is uncertain that the provincial government would support extended operation beyond 2019. This is supported by MNP's overview[65] of national and Manitoba coal policy. Mr. Sabine concluded that the number of regulations will "wean Canadian regions from the use of coal in electricity generation. Certainly that's the case in Manitoba."[66]

The opportunity to convert this unit to natural gas will also be considered. However, the age of the unit, the low efficiency that would result with conversion to natural gas (as

7.0 TRANSMISSION

7.1 MH Position: Transmission Plan Meets Reliability Criteria

The technical analyses undertaken by Manitoba Hydro for the transmission portion of the Preferred Development Plan demonstrate that the proposed transmission facilities are technically justified as consistent with Manitoba Hydro reliability criteria and NERC reliability standards that have been adopted pursuant to provincial law. This position is supported by Independent Expert Consultants Power Engineers ("PE") and La Capra and Associates ("LCA").

7.2 Reliability Criteria

In its May 2014 Rebuttal Evidence filed in this proceeding, Manitoba Hydro identified the applicable NERC reliability standards related to transmission planning that were used in the analysis of the proposed transmission facilities. In addition, several internal criteria were identified that have been voluntarily adopted by Manitoba Hydro to ensure the continuance of an adequate supply of electricity for Manitobans, in accordance with its corporate mandate under *The Manitoba Hydro Act*. The key criteria include:

- Manitoba Hydro Generation Planning Criteria (NFAT Appendix 4.1) – These criteria include a capacity criterion that ensures a minimum generation reserve of 12% above the demand forecast as well as an energy criterion to ensure sufficient resources are available to supply the energy needs in the event that the lowest recorded river flow conditions are repeated.
- NERC Transmission Planning Standards TPL-001 through TPL-003 – These criteria determine the minimum transmission requirements needed to meet the performance criteria for withstanding credible single and multiple contingencies as defined in Table 1 of the NERC TPL standards.
- HVdc Adequacy criteria – Manitoba Hydro has adopted criteria in addition to the NERC standards that help to plan the HVdc system, including the following:

  (i) Since 1986, Manitoba Hydro has had an HVdc pole criterion for determining the supply adequacy in the event of a dc pole outage.

  (ii) Conducting an annual probabilistic reliability assessment regarding loss of load expectation ("LOLE") has also been used as a guideline since 1996, but was added as an explicit criterion in 2012 to comply with the new Manitoba regulations governing NERC data reporting requirements. The annual NERC long term reliability assessments require an assessment of whether the Planning Authority can meet a 0.1 day/year LOLE metric.

(iii) In addition, once Bipole III is constructed Manitoba Hydro will require the minimum of one HVdc valve group in on-line spare capability equivalent to the largest valve group above northern generation in a single northern collector system configuration (i.e. 500 megawatts (MW) in on-line valve group spare pre-Conawapa). Manitoba Hydro's initial plans were to have one HVdc valve group in on-line spare capability in each of the two isolated northern collector systems after the construction of Conawapa (i.e. 300 MW spare with Bipole I and 575 MW spare with Bipoles II and III). However the criterion to be applied after the construction of Conawapa is under review.

- NERC Standard TPL 004 – In addition to the above criteria, Manitoba Hydro also assesses the risks to reliability of low-probability high-impact events according to NERC Standard TPL-004. This NERC standard requires an evaluation of the risks and consequences of extreme contingencies but, unlike standards TPL-001 through TPL-003, does not require the transmission planner to mitigate such risks.

7.3 Technical Analyses and Conclusions

Manitoba Hydro performed extensive studies and analyses using the above-referenced criteria that support the technical sufficiency of the proposed transmission additions and upgrades to the Manitoba transmission system, the results of which are contained in the following reports. Given that the scope of work for IEC NFAT Review included the requirement to review the completeness and reasonableness of the existing transmission system as well as the new facilities proposed in the Preferred Development Plan, Manitoba Hydro provided these reports to PE and LCA, on a confidential basis, for their review:

- 2012 System Performance Assessment – NERC Planning Standards TPL-001 through TPL-004 – This assessment is performed on an annual basis, as required by the NERC TPL standards, and demonstrates that the current system as well as the planned system meets the required NERC performance requirements over the ten year planning horizon.
- Interconnection Evaluation Study Report for Keeyask, June 8, 2012 – This study and the associated report were conducted pursuant to the Manitoba Hydro Open Access Interconnection Tariff. This Tariff has been adopted pursuant to section 15.0.3 (1) of *The Manitoba Hydro Act* and outlines a process for studying and interconnecting new generating units to the Manitoba transmission system. The Tariff is non-discriminatory and applies equally to independent power producers and Manitoba Hydro-owned

generating facilities. The report examined several options, involving both firm and non-firm interconnection service, for the connection of the proposed Keeyask generating station to the Manitoba Hydro grid and confirmed the adequacy of the proposed transmission upgrades to meet the NERC TPL standards.

- Integrated Transmission Plan for Keeyask and Conawapa Generation, SPD 2011/11, June 6, 2012 – The scope of the report includes an integrated generation-transmission planning study that looked at alternatives for connecting Keeyask and Conawapa to the transmission grid. Based on the results of this study, the report recommended that the NCS be split, that the Bipole III converters be upgraded to a 2300 MW rating and that the north-south transmission be upgraded to accommodate one 102 MW Kettle unit to increase the amount of on-line dc valve group spare.
- Preliminary Group Facility Study: MHEM 1100/750/250 MW Export/Import, October 2, 2013 – This study and its associated report were conducted under Manitoba Hydro's Open Access Transmission Tariff in response to several transmission service requests submitted by Manitoba Hydro's electricity marketing business unit. The report outlined various transmission options that would increase the existing Manitoba to US transfer capability by 250 MW, 750 MW and 1100 MW, including the proposed Manitoba-Minnesota Transmission Project.

Manitoba Hydro conducted sufficient analyses to determine the necessary transmission facilities to meet reliability criteria and be included in the Preferred Development Plan. Notably, PE endorsed the thoroughness of Manitoba Hydro's 2012 System Performance assessment in their January 20, 2014 report (PE Exhibit-3, p. 14, lines 31-33).

7.4 Power Engineers and La Capra Support

Although the initial reports provided by Power Engineers (MH NFAT IEC Transmission Line Construction and Management Report, January 20, 2014), and La Capra (NFAT Review of MH's Proposal for the Keeyask and Conawapa GS – Appendix 8 Transmission, January 24, 2014) raised some initial concerns regarding the ability of the plan to meet NERC standards, these concerns were later resolved through information requests and rebuttal evidence.

In response to a concern raised by LCA that Manitoba Hydro had not provided sufficient information regarding its ability to call on contingency reserves from MISO in order to withstand a single contingency and meet compliance with NERC TPL standards, Manitoba Hydro filed Rebuttal Evidence on February 28, 2014. Section 6.4 of the Rebuttal confirms that, pursuant to the Coordination Agreement between Manitoba Hydro and MISO, MISO is obligated to provide up to 1850 MW of contingency reserves to Manitoba Hydro on a firm basis when called upon during a contingency (MH Exhibit #85, p. 81, lines 12-17). LCA testimony on cross-examination by Manitoba Hydro on April 9, 2014 indicated that LCA had no outstanding concerns with Manitoba Hydro's ability to call on contingency reserves from MISO (Tr. p. 6262, lines 5-25 and Tr. p. 6263, lines 1-5).

Similarly, uncertainties raised by PE and LCA regarding the appropriateness of curtailing Firm Transfers under NERC standard TPL-002-0a were resolved through Manitoba Hydro's Rebuttal Evidence. Manitoba Hydro demonstrated that note b of NERC TPL-002-0a allows for curtailment of Firm Transfers to prepare for the next contingency. As explained in detail (MH Exhibit #85, p.81, lines 5-34), although the automatic operation of special protection systems temporarily curtails Firm Transfers, this curtailment prepares for the next contingency and does not result in any loss of electricity supply to firm customers (i.e. "demand"). Manitoba Hydro's contingency reserve sharing arrangement with MISO, ensures there is no loss of demand following a valve group or pole loss in Manitoba. Because of this contractual arrangement, Manitoba Hydro does not have to maintain its own generation reserves equivalent to a dc pole loss or maintain the equivalent of a spare pole in DC transmission.

In light of the evidence provided, both Power Engineers and La Capra support the transmission facilities included in the Preferred Development Plan. Independent expert witness, Mr. Glenn Davidson from Power Engineers, provided the following testimony on April 11, 2014, "Our finding is that the existing Manitoba Hydro system is reliable and it meets the NERC standards. We believe that the proposed system meets the NERC reliability standards using the current Bipole III model, and that is demonstrated in Manitoba Hydro's Integrated Transmission Plan for Keeyask and Conawapa." (Tr. p. 6519, lines 8-15). Mr. Davidson also provided a presentation with two key conclusions in his direct testimony:

- "The Existing MH System is reliable and meets NERC Standards, as demonstrated in the 2012 System Performance Assessment report."
- "The Proposed System Reliability (sic) meets NERC Standards using existing BPIII model, as demonstrated in the Integrated Transmission Plan for Keeyask and Conawapa report…" (Exhibit PE-5, p. 23)

LCA's support for the sufficiency of the proposed transmission plans in meeting reliability criteria was evidenced by the direct testimony of Mr. Peaco on April 7, 2014 (Tr. p. 5536, lines 19-23).

7.5 Conclusion

Manitoba Hydro has completed sufficient technical analyses to determine a transmission plan that meets reliability criteria. The transmission plan permits the interconnection of Keeyask and Conawapa as well as an increase of 750 MW in Manitoba to US export/import capability.

7.6 MH Position: Transmission Export Limit is Reasonable

The proposed 750 MW tie line capacity increase as part of the PDP above the existing 1950 MW long term firm export level is reasonable. During summer peak and summer off peak load levels in Manitoba, it is expected that the additional tie line capacity will be fully utilized after the addition of Keeyask depending on water conditions. In Power Engineers Jan. 13, 2014 report they state on page 23, "POWER agrees that new facilities will be needed to increase the MH-US transfer capability by 750 MW, and to mitigate constraints in the MISO system."

7.7 Manitoba Hydro Analysis and Main Conclusions

Chapter 5 of the NFAT Submission presents an overview of the capability of the existing interconnections and existing import contracts. Table 5.7 on page 61 of the NFAT business case notes that the firm export schedule limit to the US is 1950 MW and in Table 5.8, the firm import limit is 700 MW. Part of the PDP assumes construction of a 750 MW capacity new interconnection with the US. This new tie line will increase the firm export schedule limit to the US to 2700 MW and the firm import limit to 1450 MW.

Section 5.1.4 of the NFAT Business case summarizes the current import capacity contract level of 500 MW (Table 5.2) plus an additional 500 MW energy services agreement that may be scheduled within the firm 700 MW import limit. There are sufficient long term transmission service requests to match with the import contracts.

Existing winter peak export commitments of 605 MW reducing to 358 MW in 2015/16 are discussed in Section 4.2.4 of the NFAT Business Case. New export contracts associated with the PDP are described in Table 6.4 of the NFAT Business Case. They include a 250 MW sale to Minnesota Power and up to a 300 MW sale to Wisconsin Public Service that are contingent on a new US interconnection.

From the information provided in the NFAT Business Case, it's not immediately clear why a 750 MW capacity interconnection is required. In the response of LCA to MH/LCA-046, they state "To date, MH has not provided documentation supporting the value used for the existing TSRs in the analysis or the basis for assuming continuation of all TSRs is a reasonable assumption." LCA stated in their direct evidence (Page 7 April 7, 2014) that "MH had not demonstrated the need for the US transmission."

Additional information was provided to help support the need in two key areas. First of all the existing transmission commitments were clarified to show insufficient available transfer capability and second it was shown that the existing system could not be upgraded without new transmission.

Transmission service reservation information for Manitoba to US export contracts was provided in response to PUB/MH II-332a. Manitoba Hydro CSI Undertaking #12 provided further details on reconciling the difference between network service and the total available transfer capability. The information provided verifies that there are approximately 1850 MW of long term yearly firm transmission service requests in place in 2020 that have rollover rights. The Manitoba Hydro Transmission Service Provider is functionally separate from the Energy Marketing function and according to the Manitoba Hydro Open Access Transmission Tariff (OATT) must assume that existing long term firm confirmed transmission service requests that are eligible for rollover will rollover unless advised otherwise by the Transmission Customer[68]. Manitoba Hydro Export Power Marketing would perform a business case analysis to determine whether they would be seeking to rollover existing TSRs.

In response to PUB/MH I-189, an assessment was provided of the transmission constraints that limit the firm export capability to 1950 MW and firm import capability to 700 MW. It was clarified in response to MMF/MH I-037 that only a minimal increase of 50-100 MW in the import limit was feasible without a major new interconnection. The response to PUB/MH II-332b clarified why there was insufficient transmission available to increase the firm export capability above 1950 MW and verified that new transmission was required to meet the 250 MW Minnesota Power export sale contract.

The NFAT Business Case focused on the ability of the PDP to meet Manitoba winter peak loads and winter export commitments (e.g. Figure 4.20 shows the need for new winter capacity); however, the Manitoba to US tie line export capacity is not sized based on winter peak needs. Manitoba Hydro takes advantage of seasonal diversity where loads in Manitoba

[68] Further evidence is provided in Section 6.7 of MH's February 28, 2014 rebuttal.

are low in the summer but high in the US. In order to secure long term transmission service, the service must be reserved on a yearly basis. In the winter, Manitoba Hydro does not fully utilize the available transfer capacity to the US, however, in the summer, depending on water conditions, the capability is fully utilized. Summer peak loads in Manitoba are approximately 70% of winter peak loads. Given a 5000 MW winter peak load, for example, means roughly 1500 MW of spare generation capacity is available for summer peak exports with more generation capacity available during off peak load periods.

7.8 La Capra and Power Engineers Support

La Capra (LCA) makes the following statement on pages 8-30, of their Technical Appendix 8, in reference to results from the MISO Wind Synergy Study, "In addition, the study found that after the new hydro (Conawapa and Keeyask) is operational and the new transmission interconnection is completed, the interface flow from MH to MISO is only increased on average by 358 MW. This indicates a less than optimal transfer on the MH-US intertie."

When asked for the basis of this statement in MH/LCA-043a, LCA referenced its response to PUB/LCA 073c, which refers to a MISO November 5, 2012 presentation. Manitoba Hydro referred LCA to slide 16 from the referenced MISO presentation[69] during cross examination on April 9, 2014. The slide demonstrates the expected Manitoba to MISO interface flow of the existing facilities as well as the expected Manitoba to MISO interface flow after the addition of a new 500 kV interconnection. The Option 1-Duluth noted on the slide is essentially the 750 MW tie line referred to in the PDP. With the addition of this tie line option, the maximum MH to MISO flow is roughly 2800 MW in the summer and roughly 1100 MW from MISO to MH in the winter. Mr. Daniel Peaco, expert witness from La Capra, agreed that using the average interface flow over a full year was not the best method to determine the increased capacity that would be gained from the new interconnection (Transcript Page 6257 Lines 1-7). He also acknowledged that the effective increase of the new interconnection was roughly 750 MW. (Tr p. 6258, line 19 through Tr. p. 6259, line 3).

Part of Power Engineers scope of work was to review and assess the technical need for the construction of the Manitoba to US tie line. On page 29 of Power Engineers report they state "POWER's assessment confirms the technical need for US transmission infrastructure to support the planned 750 MW increase in the MH-US interconnection. In our view, it is not

[69] Manitoba Hydro Book of Documents LCA – Volume 1 page 87 (Manitoba Exhibit #167-1).

feasible to increase the rating of the existing interconnection by 750 MW without the new proposed Dorsey-Blackberry 500 kV line and associated facilities."

7.9 Conclusion

The existing Manitoba to US interface is nearly fully subscribed in 2020 with 1850 MW of long term firm transmission service requests. These requests facilitate sales of surplus Manitoba Hydro generation that is available during the summer peak and summer off peak load period. It is not feasible to increase the capability of the Manitoba to US interface by 750 MW without constructing new transmission. It is expected that the 750 MW increase will be fully utilized by Keeyask during summer peak and summer off peak conditions depending on water conditions in Manitoba.

7.10 MMF Outstanding Criticisms are Unwarranted

WRA raised a few questions and concerns regarding the ability of the proposed transmission facilities to comply with applicable reliability criteria. As discussed below, Manitoba Hydro has provided ample evidence to demonstrate that these concerns are unwarranted.

7.11 Compliance with NERC TPL-002

WRA stated in their February 12, 2014 report that "As noted previously, Manitoba Hydro's existing transmission HVDC system does not meet this N-1 criterion. If Manitoba Hydro loses one of its DC poles, it can no longer transmit all of its existing hydro power from the Nelson River. Indeed, this is why it appears that some (if not all) of its export contracts allow the exports to be dropped under system emergencies." (MMF Exhibit-14, p.30) Manitoba Hydro provided Rebuttal Evidence on February 28, 2014 to explain that the Manitoba Hydro network does meet the NERC standards when note b of NERC Standard TPL-002 is taken into consideration (See MH Exhibit #85, p. 80, lines 13-31). Through the automatic operation of Special Protection Systems, Firm Transfers are temporarily curtailed, but there is no loss of Manitoba firm load. The Coordination Agreement between Manitoba Hydro and MISO outlines MISO's obligations to provide up to 1850 MW of contingency reserves on a firm basis in the event of a severe outage like a DC pole loss to prevent the shedding of firm retail load. The supply obligations for Manitoba Hydro and its export customers following an outage are defined in the export contracts (MH Exhibit #85, p. 89, lines 23-36, p. 90, lines 1-12). For HVDC outages, Manitoba Hydro is not responsible for delivering the firm export. The purchaser is responsible for making arrangements to ensure its load is supplied so that they are compliant with the NERC TPL-002-0a standard. (MH Exhibit #85, p. 89, lines 23-26, p. 90, lines 1-12)

In its response to MH/MMF-WRA-004b, MMF interprets note b of TPL-002-0b differently than Manitoba Hydro. MMF states in their response, "Note b is designed to excuse modest special case exceptions to the N-1 criteria which precludes dropping firm customers for the more common contingencies. Specifically, the Note b reference to "radial customers" allows use of a single radial line extending from the main grid to a small remote load that does not justify redundancy by, for instance, building a second long parallel line…Manitoba Hydro interprets this note b exception clause to allow dropping of massive amounts of firm load across its main AC grid upon loss of key main grid elements such as one or two Nelson River Bipoles…The note b exceptions are not permitted to 'impact the overall reliability of the interconnected transmission system.' Manitoba Hydro's interpretation of note b would do so." Based on the foregoing, MMF equates curtailment of Firm Transfers with loss of firm load. This is not accurate. Manitoba Hydro provided further Rebuttal Evidence on this issue on May 8, 2014 (MH Exhibit #85-1). In Section 1.5 of the May 8, 2014 Rebuttal Evidence, Manitoba Hydro provided reference to FERC Orders 693 and 786 that clarified NERC TPL-002, including note b. There is no limit to the amount of Curtailment of Firm Transfers as long as it can be demonstrated sufficient re-dispatch is available to prevent Non-Consequential Load loss. As noted by Manitoba Hydro, the reference to "redispatch of resources" would include the deployment of contingency reserves (MH Exhibit #85-1, p.7, lines 6-16). In Manitoba Hydro's case, curtailment of Firm Transfers of up to 1850 MW is possible without violating the standards and without any Load loss.

In WRA's direct evidence provided on May 13, 2014, Whitfield Russell still contends that Manitoba Hydro is not in compliance with the NERC Standard TPL-002 in spite of all of the rebuttal evidence provided to support Manitoba Hydro's position and in spite of supporting testimony from independent expert witness, Mr. Glenn Davidson from Power Engineers. MMF advocates a position that would require Manitoba Hydro to build significant transmission facilities at the cost of billions of dollars to meet the interpretation that "Note b is applicable to minor firm load interruptions that are costly to avoid" and ". . . automatically dropping firm customers or transfers with an SPS does not qualify as an adjustment." (MMF Exhibit-31, p. 51, 52)

WRA's position also flies in the face of Canadian law governing statutory interpretation, as well as the underlying facts. As discussed above, curtailing Firm Transfers is not equivalent to "dropping firm customers" or "firm load interruptions". Furthermore, Manitoba Hydro's obligation to adhere to NERC standards is a legislated requirement. Section 5 of Manitoba's

Reliability standards Regulation (M.R. 25/2012), enacted pursuant to *The Manitoba Hydro Act*, requires Manitoba Hydro to adhere to the NERC reliability standards adopted under Schedule 1 of the regulation, including TPL-002-0b. Accordingly, the text of this standard is incorporated by reference into the regulation. The primary rule of statutory interpretation is that words and phrases of technical legislation are used in their technical meaning if they have acquired one and otherwise in their ordinary meaning (Maxwell On the Interpretation of Statutes (1976), p.28). In this context it is worthy to note that while NERC often capitalizes and defines terminology in a standard, the phrase "System adjustment" in footnote b is not defined in NERC's Glossary of Defined Terms. Since the term "System" is defined in the NERC Glossary of Defined Terms as "a combination of generation, transmission and distribution components", an SPS would clearly be considered part of a System. However, since the word "adjustment" is not defined, it takes on the ordinary meaning, which would include both automatic and manual adjustments of the System.

For the existing TPL standards, performance of an SPS is defined in Requirement R1 of PRC-012-0. For example, "the SPS shall be designed so that a single SPS component failure, when the SPS was intended to operate, does not prevent the interconnected transmission system from meeting the performance requirements defined in Reliability Standards TPL-001-0, TPL-002-0, and TPL-003-0." All of Manitoba Hydro's SPSs are fully redundant and have been reviewed by NERC and the Midwest Reliability Organization in their capacity as bodies that are authorized to monitor compliance with reliability standards under Section 3(1) of the Reliability Standards Regulation. Use of the SPS has been confirmed to be a valid corrective action to ensure system performance in annual NERC transmission planning assessments.

WRA's stated position is also inconsistent with the facts. Manitoba Hydro uses a Special Protection System (SPS) to automatically lower the power order on its HVDC bipoles following an outage of one of the Manitoba to US tie lines. The SPS is not designed to automatically drop firm customers.

7.12 Adequacy of Facilities

Mr. Whitfield Russell demonstrates his lack of understanding of fundamental concepts such as probability and expected value in his criticism of Manitoba Hydro's Preferred Development Plan and Bipole III during his direct testimony on May 13, 2014 as well as in his report "NFAT Review of Manitoba Hydro's PDP – report prepared for MMF by WRA" of February 12, 2014. On page 33 of his Feb. 12, 2014 report (MMF Exhibit-14), Mr. Russell states, "The probabilities of catastrophic contingencies are all less than the industry's loss of load expectation of one day in 10 years." On page 43 of his direct evidence presentation (MMF Exhibit-31), he characterizes the probability of an event as a 1 day in 17 year event. By stating "1 day" in his testimony, Mr. Russell is equating probability with expected value, which is incorrect. Probability is a measure of how certain we are that a particular event will occur while the expected value represents the average outcome of a series of random events repeated over a long period.

On page 31 of MMF Exhibit-31, Mr. Russell quotes the probability of a single pole outage as less than 1% or 0.01 based on the response to CAC/MH II-013b. In his calculation on page 29 of his February 12, 2014 Report (MMF Exhibit-14), he speculates that a double Bipole outage would have a probability 0.01. This is an oversimplified calculation. System reliability data was provided in Appendix A (page 11) of Appendix 13.1 in the NFAT Business Case (MH Exhibit-14). The actual probability of a forced pole outage can be calculated from the data as 2*((BP1 failure rate*outage duration) + (BP2 failure rate*outage duration))/8760 hours. Using this detail results in a historic outage probability of 0.46% per year for a pole forced outage and 0.02% for a Bipole forced outage. The data examined the last 15 to 25 years of historic operation experience. Data provided in Appendix A from the weather study, which uses a much larger data set[70], listed the summer weather outage frequency as 1 event in 17 years with an outage duration of 6 weeks. In his presentation (MMF Exhibit-31, p.43), Mr. Russell characterizes the risk of an extended loss of both Bipoles I and II as "… an event expected to occur no more than 1 day in 17 years, a 1-day-in-17-year event.", which is an incorrect representation.

Mr. Russell is sending mixed messages as to the combined reliability of the three Bipole systems. On page 34 of his presentation (MMF Exhibit-31), it states "MH's failure to evaluate these impacts seem to be an oversight in that the same type of catastrophic events that could take out Bipoles I and II could also take out Bipole III as well, trapping immense portions of Manitoba Hydro's resources". In contrast, on Page 43 of the presentation it states, "We accepted the proposition that the spare transmission capacity created by Bipole III without Keeyask and Conawapa would lessen risks and costs associated with loss of both Bipoles I and II." The former response is in reference to Manitoba Hydro's Rebuttal Evidence provided on May 9, 2014 where Manitoba Hydro provided information demonstrating the planned route and design of Bipole III is such that a common mode failure of all three bipoles is too low a probability to reasonably consider being credible requiring mitigation (MH Exhibit #85-1, p. 1, lines 8-23).

[70] Data sources include records of tornado events from 1950 to 2009 (page 20, Teshmont report January 2012)

The HVDC reliability data provided in Appendix A of Appendix 13.1 of the NFAT Business Case (MH Exhibit #14) is only part of the input data used to determine whether the Manitoba Hydro system meets the industry minimum standard loss of load expectation (LOLE) of 0.1 days/year or 1 day in 10 years. Other data includes the load forecast, load forecast uncertainty, available energy from generation, generator unit forced outage rate and duration, and export and import contract commitments. The results given in Figure 2 of Appendix 13.1, quantify the LOLE of the Preferred Development Plan as well as several alternatives and demonstrate that the PDP exceeds industry minimum standards.

7.13 Need for US Tie Line

Mr. Russell makes the following claim on Page 33 of his May 13, 2014 presentation (MMF Exhibit-31), "The 2000 MW spare transmission capacity initially created by adding Bipole III will drop when Keeyask is added and virtually disappear once Conawapa is added. Under the PDP, Manitoba Hydro plans to upgrade its ability to import capacity from the USA to replace the diminishing spare capacity in Bipole III." Further on Page 48, he states "In the NFAT, the hydro-based plans call for filling the spare capacity of Bipole III with the output of Keeyask and/or Conawapa. This would diminish the ability of Bipole III to provide spare capacity to cover the loss of both Bipoles I & II." Mr. Russell misunderstands the various criteria that were used to plan the transmission system in spite of Manitoba Hydro's attempts in Rebuttal Evidence provided in Section 6 on February 28, 2014 (MH Exhibit #85, p. 78-90) and further Rebuttal Evidence provided in Section 1.2 on May 9, 2014 (MH Exhibit #85-1 p. 1-4). Mr. Russell is confused about how the transmission plan is designed to respond to frequent events (e.g. valve group or pole outages covered by NERC Standard TPL-002) and infrequent events (e.g. Bipole I/II outage covered by NERC TPL-004).

First of all, the transmission capacity of 2000 MW being added by Bipole III in 2017 will not change until Conawapa is added and additional facilities are added to upgrade the transmission capacity to 2300 MW. In the event of a loss of Bipoles I and II, Bipole III can deliver 2000 to 2300 MW of Northern collector system generation. This role does not change with the addition of Keeyask and Conawapa as was also stated in MMF/MH II-020a.

Second of all, Mr. Russell is partly correct in stating that the on-line spare HVDC capability needed to deal with more probable events will reduce as Keeyask and Conawapa generation are added. However, Manitoba Hydro plans to maintain a reliability margin equal to the largest valve group (i.e. 575 MW post Conawapa) spare above generation connected in the NCS to ensure that frequent HVDC valve group outages do not require reliance on MISO contingency reserves. The on-line HVDC spare does not "virtually disappear", (MMF

Exhibit-31 p. 33) as Mr. Russell infers. In his own calculations on Page 24 of his February 24, 2014 report (MMF Exhibit-14), he notes 567 MW[71] of spare capability post Conawapa, assuming a single Northern Collector system, compared with today's system spare of 292 MW. Once Conawapa is added, Manitoba Hydro plans to split the Northern Collector System into two isolated networks as explained in Dr. Jacobson's testimony and direct evidence (MH Exhibit #95, p.83) on March 10, 2014. As noted in Manitoba Hydro's Rebuttal Evidence of May 9, "Manitoba Hydro's initial plans were to have 300 MW of on-line HVDC spare with Bipole I in Northern Collector System 1 and 575 MW of on-line HVDC spare with Bipole II and III in Northern Collector System 2, however this criterion is under review (MH Exhibit #85-1, p. 3, lines 5-9), the Preferred Development Plan has 677 MW of on-line DC spare, which implies Conawapa should be derated by 200 MW. However, the Preferred Development Plan derated the firm capability of Conawapa to 1300 MW and increased the north-south transfer capability by 185 MW with additional transmission of which 102 MW is used by a Kettle unit. Rather than derating Conawapa below 1395 MW, future Open Access Interconnection Tariff studies will consider using Manitoba spinning reserves (150 MW available) to cover loss of the largest valve group, if insufficient on-line DC spare is available.

Manitoba Hydro does not plan to upgrade its import capacity to the US to replace diminishing on-line spare HVDC capacity as suggested by Mr. Russell (MMF Exhibit-31, p. 33). The PDP has been planned to ensure it meets Manitoba Hydro's criteria of maintaining a reliability margin equal to the largest valve group (i.e. 575 MW post Conawapa) spare above generation connected in the NCS, as pointed out in the Rebuttal Evidence (MH Exhibit #85-1, p.3, lines 1-9). A key component of the PDP is the 750 MW tie line. The new tie line improves import capability, which does provide an additional benefit that Manitoba Hydro peak load can be served in the event of loss of both Bipoles I and II. However, the line is being justified mainly to increase exports to the US in order to sell increased energy available from Keeyask and Conawapa. If the sales were cancelled and the new 750 MW tie line was not built, Manitoba Hydro would continue to assess the risks and consequences of extreme disturbances, as per NERC Standard TPL-004, and would make a decision in the future whether future system changes are justified.

Mr. Russell completely misunderstands the value of Bipole III in his comparisons of Bipole III with an import line. He states, "Moreover, by insisting that a new US tie be accompanied by an additional 1500 MW of gas generation, MH creates an apples-to-oranges comparison because all that Bipole III provides (if Keeyask and Conawapa are not built) is an alternative

[71] 567 MW becomes 575 MW if the firm generation level of 3554 MW is used instead of 3562 MW.

path for MH to reach its existing Northern Hydro. It does not create an additional 1500 MW of generation. Under MH's logic, Bipole III should also be backed up by 1500 MW of generation. In reality, a 1500 MW tie to the US has access to an array of generation sources while Bipole III can access only existing Northern generation" (MMF Exhibit-31, p. 46). However, this position is unfounded. There is 3554 MW of firm Manitoba Hydro owned hydro generation in the Northern Collector System. In the event of loss of Bipole I and II, all of this generation is isolated and not able to supply load. Bipole III allows 2000 MW of this firm generation in the NCS to be delivered to load year round at no cost. The worst case outage duration considered during the Bipole III hearings was two to three years. However in the resource adequacy analysis one year was assumed for failure of the Dorsey converter station (see MH Exhibit #14, Appendix A of Appendix 13.1 from the NFAT Business Case). In order to be equivalent to the reliability provided by Bipole III, alternatives had to be able to provide firm power for one year. 2000 MW of gas turbines in Manitoba or 500 MW of gas turbines in Manitoba with a 1500 MW tie line backed up by 1500 MW of firm generation were in fact an apples-to-apples comparison with Bipole III.

8.0 DEVELOPMENT PLANS

8.1 Manitoba Hydro Has Formulated a Sufficient Number of Feasible Development Plans for the NFAT

Manitoba Hydro's development plans are the result of rigorous vetting and multi-year processes that considered all feasible options. The formulation of each of the 15 development plans included in Chapter 8 of the NFAT Business Case and the 19 development plans with various levels of DSM, provided subsequently, is based on the need for new resources and the requirement to achieve a reliable and dependable supply of bulk power for the system in Manitoba through the application of Manitoba Hydro's Generation Planning Criteria. The purpose of each development plan and the strategies and components of the various development plans is described in Chapter 8 of the NFAT Business Case. Plans are determined in consideration of various strategic business opportunities and are comparatively evaluated to identify the most favourable plan for Manitobans from an overall perspective.

In the NFAT pre-hearing conference of May 2013 (Tr. p. 46, line 25) Manitoba Hydro informed the PUB that analysis on higher levels of DSM as a resource option would not be available for inclusion in Manitoba Hydro's August 2013 NFAT submission. Manitoba Hydro's NFAT Business Case did include analysis to test the effect of higher levels of DSM on select development plans. Subsequent to the August 2013 NFAT submission, Manitoba Hydro provided a substantial amount of information and analysis (MH Exhibit #104 and MH Exhibit #171) on three additional levels of DSM which, in combination with the original base DSM, enabled four DSM options to be evaluated. All development plans include a base level of DSM.

The table below summarizes the 19 additional development plans which were included in the DSM evaluation performed subsequent to the filing of the NFAT Business Case.

Plans Included in the DSM Evaluation

Development Plan	Level 1 DSM	Level 2 DSM	Level 3 DSM	Level 2 DSM with Pipeline Load	Level 3 DSM with Pipeline Load
1. All Gas	x	x	x	x	x
2. Keeyask/Gas		x			
4. Keeyask/Gas/250 MW*		x			
5. Keeyask/Gas/750 MW with WPS	x	x	x	x	x
6. Keeyask/Gas/750 MW		x			
12. Keeyask/Conawapa/750 MW No WPS		x			
14. Keeyask/Conawapa/750 MW with WPS	x	x	x	x	x

*Note: Plan 4 is considered hypothetical from a business perspective.

Even with the volume of analysis provided by Manitoba Hydro in the NFAT process, one of the key findings contained in the direct evidence of La Capra (LCA Exhibit #45, Slide 7) is that Manitoba Hydro's alternative development plans were too limited.

The additional plans proposed by La Capra are: an All CCGT Development Plan, a No New Generation Plan, Sensitivity to the Wind/Gas Plan (Plan 3) and an Alternative Hydro Based Plan.

All CCGT Development Plan – La Capra requested that Manitoba Hydro provide an alternative all CCGT Gas Plan (Tr. p. 5598, line 5), alleging that the All Gas Plan used by Hydro was not optimized. Manitoba Hydro provided to La Capra the results of the 27 scenarios for the All CCGT plan. Mr. Peaco conceded "The combined cycle case actually was slightly less economic overall on the – on the –the analysis, but there – it – it was not very different."[72] The expected value of the All CCGT plan was $180 M NPV less economic than the All Gas Plan, and the All CCGT plan was less economic under 80% of the potential conditions[73].

No New Generation Plan – La Capra proposed a development plan with the intent of deferring new generation as long as possible. The development plan includes increased DSM and fuel switching, a new 750 MW interconnection, relaxation of the import criteria to allow up to 20% of Manitoba Load to rely on import energy, and extension of the existing Diversity agreements to the end of the 35 year detailed planning horizon[74]. La Capra

[72] Transcript page 5599, line 18
[73] La Capra Appendix 9A&B update p 22– Figure 9-95U
[74] LCA Exhibit 45, Slide 29

accepted and described this plan as "hypothetical" [75], but then proceeded to present and analyze it as a viable development plan.[76] The LCA No New Generation plan can only be considered as a hypothetical development plan as explained in Section 8.5 and provided little or no new information.

Wind/Gas Plan (Plan 3) – The LCA Wind/Gas plan is not a new development plan but is described by La Capra as a wind cost assumption sensitivity[77]. In the analysis presented by La Capra, the Manitoba Hydro Wind/Gas development plan was not modified but the cost assumptions in the economic analysis evaluation were changed by La Capra to lower the capital costs, increase the capacity factor, and extend the life of the assets[78]. Mr. Peaco conceded that even with the "relatively optimistic scenario" in the economic analysis the Wind/Gas scenario is still less economic than the Preferred Development Plan[79].

Alternative Hydro Based Plan – Mr. Peaco testified that La Capra combined the results from Plan 1 and Plan 2 to create Plan 2A which adds gas generation first, and then Keeyask Generating Station. La Capra concluded that the NPV of Plan 2A and Plan 2 were "exactly the same", and the benefits of Keeyask would be preserved if the plant was deferred.[80] Manitoba Hydro discusses the economics of Keeyask Generating Station or natural gas generation as the next resource to meet Manitoba load in Section 10.3.1 of this Final Argument.

To summarize the information provided by La Capra's proposed additional development plans, the All Gas CCGT plan proved to be less economic than Plan 1 All Gas; the LCA No New Generation plan is hypothetical and all of the main elements of the plan have already been considered in Manitoba Hydro's development plans; the LCA Wind/Gas analysis provides an optimistic view of wind in the future and can only be considered as a stress test. The economic impact of La Capra's alternative No New Generation plan, Wind/Gas Analysis and Gas/Keeyask plans are discussed further in Section 10.3.2.

8.2 Need and Opportunity

As previously outlined in Section 5.4 – The Need for New Resources, using the 2013 planning assumptions at base DSM, total demand is projected to exceed existing supply beginning around 2023 even with no new export commitments. The need for new supply to meet Manitoba domestic load is a primary driver for the development plans formulated in the NFAT Business Case. Increased levels of DSM will defer the need for new resources to serve Manitoba load.

There currently is a tremendous opportunity for the development of a new transmission interconnection facilitated by long-term export sales from large new hydro resources advanced prior to the need to serve Manitoba load. As recognized by Mr. Bowman, "There are two possible competing visions – one based on Need and one based on Opportunity – both of which are valid."[81] Mr. Bowman concludes that "Given the information available, an Opportunity-based vision (advance Keeyask, take up MP export deal, build new transmission to US) is likely better than a Need-Based vision utilizing Plan 1 (All Gas)."[82]

8.3 Opportunity

8.3.1 New Major Transmission is Beneficial

Manitoba Hydro's Preferred Development Plan takes advantage of the tremendous opportunity that exists today to build transmission which will provide Manitoba Hydro with increased firm transmission access extending into Minnesota and Wisconsin in perpetuity. At the outset it is important that the Board recognize that the benefits associated with this opportunity are broad and as Mr. Cormie testified are not confined to just the benefits associated with firm export sales.

> "So the basket of benefits that Manitoba Hydro receives as a result of the big line is quite broad, and to only look at the firm power sale as the only benefit ignores other -- the other benefits that -- that are there." (Tr. p. 2651, line 8)

It is also vital that the Board understand that this opportunity is time sensitive. It would be a critical error to assume that Manitoba Hydro can defer acting on this opportunity and expect that the same or even a similar project will be available at a later date. The Great Northern

[81] Pre-filed Testimony of P. Bowman, pages 1-5.
[82] Pre-filed Testimony of P. Bowman, pages 1-7.

Transmission Line project is at best a once in a lifetime opportunity. Again in the words of Mr. Cormie:

> "And—and I-- I think when I look at this project -- and think about all the broad things --the broad basket of benefits it brings, you know, I -- I -- and knowing how valuable interconnections are -- are and how difficult they are to build, you know, it's my judgment and -- and Manitoba Hydro's judgment that -- that this is something that we have an opportunity to go for now, and that we should -- we should do that, and that -- that's why it's kind of in our - in our plans as this is a must. This will provide long-lasting value to the Company." (Tr. p. 2651, line 14)

Benefits of new transmission include improved system operation reliability, improved system import capability for buy/sell opportunities and drought supply, and expanded access to US markets to maximize Manitoba Hydro's system operations with the benefit of selling dependable energy for securing firm revenue from long term export sales and surplus energy for additional export revenue. All of these benefit the Manitoba ratepayer and Manitoba.

Additional transmission capacity is necessary to maximize the value of Keeyask, Conawapa and DSM investments. The interconnections make the economics of hydro generation work. As Mr. Bowman testified, "you can only do it with transmission" (Tr. p. 10068, line 9) in reference to maximizing the value of hydro.

A new 750 MW transmission line with Keeyask would support development pathways that involve Conawapa and associated major export contracts. This includes the signed 308 MW Wisconsin Public Service sale contract which is dependent upon the new MISO firm transmission reservations that reach into Wisconsin associated with the new line (Tr. p. 1586, line 11). Not proceeding with the 750 MW line would result in a loss of these reservations leaving Manitoba Hydro's access into Wisconsin limited to 100 MW (PUB/MH II-332i).

As noted by Mr. Bowman, building more hydro, even for just Manitoba load, increases the need for new transmission because new hydro increases the amount of surplus energy. New transmission allows the surplus energy to get to the US market and export sales revenue to be earned in the valuable on-peak period rather than the lower priced off-peak period. The generation is required for system reliability and without the transmission, the water to produce hydro energy is spilled in Manitoba and no revenue is captured. "So even if you're only building for your own needs…you still need more and more transmission over time" (Tr. p. 10068, line 15).

As indicated by Mr. Cormie, the transmission used to reach the MISO market has to be firm transmission, as non-firm transmission is subject to curtailment because Manitoba Hydro is not in MISO. If imports from Manitoba cause congestion in MISO and Manitoba Hydro is using non-firm transmission service, MISO will cut the import schedule, Manitoba Hydro spillways will open and the energy will be lost. (CSI Tr. p. 521, line 1). All of Manitoba Hydro's existing MISO firm transmission is required to manage Manitoba Hydro's existing energy surpluses (CSI Tr. p. 522, line 13).

Indirect benefits of the 750 MW interconnection include increased import capability and improved reliability at no additional cost. La Capra concurred stating "it looks like every plan we have with transmission in it, to some level, so long as it includes some import capability, it has some value." (Tr. p. 5701, line 19). Mr. Bowman stated:

> "The information we reviewed suggests that the 750 MW line brings benefits even if you never built Conawapa. The latest information also suggests, ... that your economic benefits and the value from things like DSM are improved by having the line. The line isn't doubling down on product – on future production. It's also doubling down on future energy savings. It improves – improves all of your future scenarios." (Tr. p. 10084, line 8).

Building new US transmission needs a US champion. New transmission needs to be permitted in the US by an entity who can demonstrate "need", in order to serve US load and who has the ability to successfully finesse a Presidential Permit for an international transmission line from the US government (Tr. p. 1334, line 4). Manitoba Hydro's President Mr. Scott Thomson testified "so we get our US customer to build a transmission line that we would never get built without them". (Tr. p. 221, line 3)

The timing of this window of opportunity is critical. Mr. Cormie explained that the new transmission is part of a "window of opportunity" for Manitoba Hydro to work with our neighbours in a manner that maximizes the benefit for all parties but it's a limited opportunity:

> "...they are also making strategic decisions now. It's a limited opportunity because we've convinced them over the past several years to expand their set of planning options to include significant reliance on Manitoba Hydro.
>
> ...

> These companies have seen values in these offers, and have seen the value of having increased certainty. On the basis of our long-standing reputation with them, they have agreed that this is an opportunity for them too, in facing the future with Manitoba Hydro as a partner. This opportunity won't come again soon.
>
> ...
>
> With these contracts, these utilities are choosing not to build alternate supply resources, but to rely on Manitoba Hydro as the supplier. Without these contracts, these utilities will invest in other long-term supply options to meet their needs. The opportunity for Manitoba Hydro to displace these other options will not return. They will be lost." (Tr. p. 1310, line 9 to Tr. p. 1312, line 15)

In a discussion between Dr. Bel and Mr. Chernick on May 1 regarding the wisdom of proceeding with Keeyask and the interconnection when load growth in Manitoba potentially could run flat, Mr. Chernick suggested that all the other benefits Manitoba Hydro would secure could be a very good investment even without the Manitoba load.

> "... Manitoba is not an island, and you have an unusually good opportunity here to do the right thing and reduce environmental damage and make money at the same time, and -- and help out your neighbours to the south, as well. And it's entirely possible that Keeyask and -- and the transmission line will be part of a long-term strategy to do that." (Tr. p. 9790, line 5)

Morrison Park Advisors (MPA) witness Mr. Pelino Colaiacovo noted that it should not be presumed that amendments to the commercial arrangements between Manitoba Hydro and its US partners can be easily achieved or achieved at all. (Tr. p. 7254, line 9-21). Mr. Colaiacovo placed high value on these commercial arrangements:

> "These are actually negotiated commercial agreements. This is a bird in the hand. And if they are going to be rejected in favour of an alternative, there is a very high burden on alternatives to be demonstrated to be significantly superior to the real package and the real opportunity that—that is before us in completing the Keeyask construction and in the 750 megawatt intertie and all the associated export contracts." (Tr. p. 7256, lines 6-14)

When asked whether failing to start construction of Keeyask in the summer of 2014 would result in loss of all opportunities to build the transmission line, Mr. Bowman provided a conclusion similar to that of Mr. Colaiacovo, emphasizing the required confluence of events to achieve the benefits of the Preferred Development Plan:

> "No, but...There's room for some delays , we've heard, but not much. And having been involved in developing these type of –of projects, there is a mind bogglingly long list of—of balls in the air, of juggling of rings in the circus that somebody is trying to orchestrate to make all these pieces of the plan come together.
>
> And—and as—as Morrison Park was saying, when they do, you have to recognize it as something different. And—and Keeyask, shovel in the ground this summer, is one piece of that. You—you—it's not a buffet. It's a coherent option that—that's set out.
>
> It may be that there's reasons to move it, but when you have a –a contractor and a counterparty and financing markets and Aboriginal partners and licenses and the federal government and –and, you know, everything from, you know unions to governments moving in a a certain direction and you've managed to get this choir to sing together, it's –it's very hard to say, Oh wait, wait, wait I want – I want to change this one." (Tr. p. 10227, line 21)

8.3.2 Both the Minnesota Power Sale and Upsizing the US Transmission Line From 250 MW To 750 MW, are Dependant on Minnesota Power Having a Transmission Investment Opportunity

Transmission investment is a condition of Minnesota Power's and Manitoba Hydro's power sale arrangements (MH Exhibit #201) in order to offset the financial effects of the 250 MW Sale Agreement on Minnesota Power's balance sheet. Minnesota Power will pay all the costs for 250 MW of new US transmission line capacity.

Mr. Wojczynski testified that although it was studied, a 250 MW transmission interconnection is not an option for Minnesota Power and as a result not an option available to Manitoba Hydro. "Manitoba Hydro has not said that we prefer to do the seven fifty (750) over the two fifty (250). What we said is that the two fifty (250) option, as it stands now, is not a viable option, and is not an option available to Manitoba Hydro. It's off the table." (Tr. p. 2874).

Mr. Cormie testified that the 250 MW transmission line is not an option. Minnesota Power, in their Certificate of Need filing for the Great Northern Transmission Line (GNTL), have stated "that a 250 megawatt project would not meet the long-term needs of the region, would not prove to be cost effective for their customers, nor is it the environmentally preferable line over the long term." (Tr. p. 1335, line 10).

Further, as indicated in the response to LCA/MH I-037 (pages 3-4), the 250 MW interconnection is significantly more expensive for MP, is not as advanced and does not provide significant economic or reliability benefits to Minnesota or the MISO region. As such, a 250 MW interconnection has significant risk of not being approved and proceeding. In contrast, the new 750 MW line is attractive as it facilitates additional innovative wind storage provisions that optimize the value of Minnesota Power's wind energy investment, and when combined with increased storage capacity improves savings in production costs, load costs, and reserve costs as well as reduced wind curtailment. Recognizing Manitoba Hydro's longer term need for more interconnections, building the new tie line large enough the first time will limit proliferation of new transmission line corridors in the future. A lower capacity line greatly reduces these utility, state and regional benefits.

Plans with a 750 MW line provide significant benefits making the line worth pursuing. Given Minnesota Power's statutory right to own, invest and earn on 100% of the 750 MW transmission line, an arrangement where Minnesota Power's ownership share is 51% has been negotiated (Tr. p. 1326, line 20). Manitoba Hydro is satisfied with the negotiated 51% level of transmission line ownership by Minnesota Power, because as Mr. Thomson testified on March 3, 2014 "we don't want to hold a majority interest in a US asset." (Tr. p. 112, line 3).

Negotiations with Minnesota Power on the business arrangements associated with the proposed 750 MW line have evolved from the time of the NFAT filing in August 2013. During the hearing Mr. Cormie updated the Board on these arrangements, indicating that Minnesota Power will invest in 51% of the GNTL compared to the NFAT funding assumptions which included a 55% Minnesota Power ownership assumption as described in detail in MH Exhibit #139 and MH CSI Exhibit #17.

The issues of GNTL ownership, investment, use, and funding are complex, and remain under negotiation by Manitoba Hydro and Minnesota Power. However the key terms of the proposed arrangements are expected to be as follows (Tr. p. 1326, line 3 to Tr. p. 1328, line 8);

1. Minnesota Power will develop, permit and construct the GNTL.

2. Manitoba Hydro will have the right to offload its ownership position to a third party.

3. All the firm US transmission rights to move electricity across the border (exports and imports) will be held by Manitoba Hydro, Wisconsin Public Service and Minnesota Power, with Minnesota Power's rights limited to 383 MW in the southbound direction associated with its power purchase from Manitoba Hydro.

4. With regard to GNTL funding;

    a) Minnesota Power will have funding responsibility (33%) for the transmission needed for the 250 MW Power Sale Agreement, and
    b) Manitoba Hydro will have funding responsibility (66%) for the additional investment necessary to bring the capacity of the line up to 750 MW.

Manitoba Hydro's funding for the 66% share will be achieved in two different parts, 49% directly as a result of Manitoba Hydro's ownership position and 18% via a scheduling fee payable to Minnesota Power to cover its increased revenue requirements associated with the additional 133 MW (18%) of capacity it will own above that necessary for the 250 MW Power Sale Agreement. Manitoba Hydro's expected funding responsibilities remain consistent with those assumed in the NFAT no-WPS-investment analyses. (CSI Tr. p. 246, line 5)

The 18% scheduling fee arrangement will be paid on an ongoing basis over the life of a 133 MW Energy Sale Agreement under negotiation (CSI Tr. p. 108, line 10 and Tr. p. 1669, line 7). In exchange for this fee, Manitoba Hydro will have the rights to use the 133 MW to export and import energy. The fee will be set to offset the increase in Minnesota Power's revenue requirements as a result of owning and operating a larger portion of the GNTL. This includes earning a rate of return on the additional equity Minnesota Power invests into the transmission line. Mr. Cormie testified with respect to Minnesota Power "They're investing the additional 18 percent on behalf of Manitoba Hydro, and they expect to earn on that 18 percent." (Tr. p. 1584, line 10).

8.3.3 Minnesota Power 250 MW Sale Tied to Early Keeyask

Manitoba Hydro and Minnesota Power have signed a 250 MW System Power Sale Agreement with deliveries to commence on June 1, 2020. As set out in MH Exhibit #201, the commencement of construction of Keeyask is a condition precedent in the Agreement in favour of Manitoba Hydro. While there is no condition precedent in the Agreement in favour of Minnesota Power, both parties to the Agreement have conducted themselves based on the shared understanding that if construction of Keeyask does not commence by June 1, 2016, the Agreement will terminate and no interconnection will be built. This shared understanding is confirmed in the Energy Exchange Agreement signed contemporaneously with the 250 MW Sale Agreement, the Preamble of which sets out this understanding:

> "AND WHEREAS, MP is developing significant wind resources and desires to pump and store wind energy, in conjunction with the construction of a new transmission interconnection between MP and MH and MH's proposed new hydraulic generation development;"

Further, with regard to the new US interconnection, Manitoba Hydro has represented to Minnesota Power that the need for it is based on increased amounts of exports of surplus capacity and energy destined for the MISO market resulting from the construction of Keeyask and Conawapa. Minnesota Power echoed this justification in its Certificate of Need filing and its ongoing proceedings for the Great Northern Transmission Line with the Minnesota Public Utilities Commission. The Certificate of Need identified Manitoba Hydro's plans for major new hydraulic generation as justification for a 750 MW interconnection and specifically identified Keeyask as being needed for the supply of power under the Agreement.

On this side of the border, the Province of Manitoba's Order in Council 304/11 authorizing Manitoba Hydro to enter into the 250 MW MP Sale Agreement references the need for Manitoba Hydro to construct new power generation in order for Manitoba Hydro to fulfill its obligations under the contract.

Mr. Cormie indicates that "Minnesota Power requires the new generation early in -- either in 2020. They can -- they can cope with a delay up to '22. The contract reflects that. Anything beyond that date does not work to meet their -- their load requirements, and -- and a delay to 2031 or -- or some later date, it's not -- it's not part of the -- of the contract." (Tr. p. 9894, line 17). This accurately represents the business arrangement carried out in good faith between the Parties. It would be unrealistic to think one could foist an alternative arrangement not involving major new hydraulic generation upon Minnesota Power. As noted by Mr. Colaiacovo,

> "Commercial negotiations are just that; they're negotiations between independent parties. And while all in -- all of us external experts and all Intervenors and -- and commentators and analysts external to the situation, to the transactions between Manitoba Hydro and its -- and its partners, can question whether those particular transactions may or may not be the best transactions which could have been negotiated, the reality is those are the contracts and arrangements that have been negotiated. And they can either be accepted or rejected. And it shouldn't be presumed that amendment can be easily or achieved at all." (Tr. p. 7254)

It is important to recognize that like Manitoba Hydro, Minnesota Power must demonstrate the benefits of this arrangement to its regulator. It must be a win-win transaction in order for it to move forward. If Keeyask does not commence by June 1, 2016 the MP 250 MW Sale Agreement will terminate and no interconnection will be built.

With the apparent attractiveness of expanded Demand Side Management, there have been suggestions that Manitoba Hydro could have the option of serving Minnesota Power's capacity and energy needs as outlined in the 250 MW Agreement from surplus dependable hydro energy, freed up as a result of lower Manitoba load. This would not be an acceptable source of supply for Minnesota Power, as increased DSM does not provide the additional wind synergy benefits associated with the construction of new hydraulic generation.

The benefits to Minnesota Power of expanded DSM in Manitoba are significantly smaller than the step function changes that would occur if both Keeyask and Conawapa are built. In addition, new storage at Conawapa makes the Manitoba Hydro storage battery significantly bigger and the loss of the associated benefits from wind hydro synergy would be a very significant issue (Tr. p. 1671, line 21).The loss of new wind synergies would also be important to the state and to MISO as new storage leverages many more MW's of potential wind development in the US.

In theory a new relationship with Minnesota Power could be established over time around a development plan based upon freed up resources as a result of expanded DSM. However Minnesota Power needs new resources to serve its load in 2020, and it is Manitoba Hydro's view that if Keeyask does not proceed prior to June 1, 2016, Minnesota Power will chart a different course to meet its 2020 load requirements without Manitoba Hydro.

Manitoba Hydro is firmly of the view that Minnesota regulatory approval for the Great Northern Transmission Line would be at significant risk if Keeyask does not proceed given that the Minnesota benefits of the 750 MW interconnection could not be realized. The Minnesota statutory "need" justification to build new transmission would no longer be satisfied as the existing Manitoba–US interconnection has adequate capacity to manage Manitoba Hydro's current surplus energy supplies. Further, a recommendation in Manitoba that at this early juncture rules out the possibility of developing Conawapa in the future could also have serious repercussions for obtaining approval in Minnesota of the 750 MW interconnection.

Manitoba Hydro submits that the construction of the 750 MW interconnection without a commitment to build Keeyask is not a viable option.

8.3.4 Manitoba Hydro's Sales Activities Reduce Export Price Risk

Manitoba Hydro's Preferred Development Plan includes the early construction of both Keeyask and Conawapa which can be expected to produce over 11,400 GWh of new hydraulic generation per year on average. (Chapter 2, NFAT Overview). Manitoba Hydro has been actively marketing both the surplus dependable and other surplus energy from these stations since 2007 in order to capture premium fixed prices, minimize financial risk and to facilitate a major new interconnection to the US. As Mr. Thomson confirmed, financial risk associated with uncertain dependable and surplus export prices is a major risk to the Corporation (Tr. p. 168, line 2).

To date Manitoba Hydro has been successful in selling most of the dependable output of Keeyask and 30% of the output of Conawapa at fixed prices which has significantly reduced the risk of these projects, especially Keeyask. "The contracts that have been signed to date for hydraulic energy effectively use up most of the surplus power -- hydro power available from Keeyask." (Tr. p. 1312, line 16). With regard to the significance of the fixed price 308 MW WPS sale, Mr. Cormie explained "To put the size of the sale in context, the energy quantities associated with this sale are significant, relative to Conawapa. It's 33 percent of its generation under dependable flow conditions, and under average flow conditions it's 29 percent of Conawapa generation." (Tr. p. 1322, line 7).

The remaining gap in unsold dependable energy until Conawapa is built is associated with the additional dependable supply made available as a result of the new interconnection (Tr. p. 1328, line 3). Mr. Cormie indicates there is much more customer interest than unsold product remaining.

> "... all of the discussions that we are having with the various customers exceed the dependable energy supply line that we're showing there. And so we're in discussions for more dependable energy post-Conawapa than -- than we have -- have supply. So there is room there. And there's market interest there to -- to increase, should the Manitoba load be lower. And -- and we are continuing to seek out all opportunities, so that at the end of the day, we can bring back the best value and best portfolio to -- to fill the -- to fill that -- to fill that gap, or whatever it is." (Tr. p. 1512, line 11)

Expressed interest exists, particularly with SaskPower and Great River Energy. Both have recently signed MOUs with Manitoba Hydro. Mr. Cormie indicates that with Saskatchewan we "are working quickly on several stage[d] long-term sales that would require Keeyask and Conawapa." (Tr. p. 1313, line 8). And "Again, it is a -- there's a 500 megawatt MOU, and under that MOU, discussions are occurring for a -- an earlier power sale that would be dependent on Keeyask, and then a larger power sale that would be dependent on Conawapa. And again, Saskatchewan knows when our investment decision needs to be made and it aligns with the years in which they need the power." (Tr. p. 2419, line 3).

With regard to Great River Energy, it signed a Memorandum of Understanding for 600 MW for long term power from Keeyask and Conawapa in February 2014. (Tr. p. 2416, line 13) As confirmed in MH Exhibit #95, it is expected that the Northern States Power sales will be extended in 2025. Mr. Cormie testified that "Manitoba Hydro and NSP expect to extend that sale for ten (10) years, but that extension is not shown here."(Tr. p. 1317, line 24).

These expressions of interest are not yet formalized into signed contracts, and as such the need for Conawapa will be reviewed on an ongoing basis. Manitoba Hydro intends to continue to undertake studies for an early Conawapa in service date, and will reevaluate its plans in the next power resource planning exercise. Manitoba Hydro expects that if conditions are favourable, including progress on export power negotiations, it will continue to plan for an early Conawapa (Tr. p. 2588).

8.3.5 New Hydro Is a Unique and Valuable Export Product

As indicated in response to GAC/MH I-028 Manitoba Hydro's long term firm export product is needed and valued in the export market because it is a unique product that our counterparties do not have themselves, unlike gas and wind resources. The contracts are tied to the development of major new hydro generating resources with associated renewable attributes. Manitoba Hydro is unique in being able to offer a large dispatchable hydro supply option to its export customers. Other Manitoba Hydro options are not of interest to Manitoba Hydro counterparties because they have their own supply options such as wind, natural gas or DSM, which can be developed locally at a lower cost than from Manitoba.

Mr. Cormie confirmed that US utilities do not need or want to buy wind and gas generated power from Manitoba, as they have ample supplies of their own. "They're adding wind and they're adding gas. So our resource is no better than -- than the resource that they can put in place themselves, because there's lots of wind and they have access to gas." (Tr. p. 2108, line 8).

Not only do they have their own wind resources, US utilities are able to install wind at less cost than Manitoba Hydro because the United States government offers a production tax credit on wind. Mr. Cormie explained, "but they also have the advantage of the production tax credit, and so for us to assume that we could find the customer who wants to buy our wind gas product, and -- and use that in -- as opposed to doing it themselves, the -- something would have to happen to the economics of wind in Manitoba." (Tr. p. 2108, line 13).

With regard to whether existing hydro freed up by expanded Demand Side Management is an acceptable alternative to new hydro, evidence was provided on page 2 of MH Exhibit #201 that for Minnesota Power, it specifically wants new hydro because of the new benefits associated with expanded storage in Manitoba.

> "Part of the benefits MP has identified in the CON filing for the 750 MW interconnection are the result of increased imports to Minnesota associated with a large increase in hydraulic energy production from new generation at Keeyask and Conawapa in the form of: a) additional environmental attributes; b) significant wind synergy benefits to MP, other Minnesota utilities, and regional MISO load as indicated in the MISO-MH Wind Synergy Study; and c) lower Locational Marginal Prices at the MP-MISO pricing nodes."

Finally it should be noted that the Wisconsin Public Service 308 MW Agreement is tied solely to the new capacity and energy associated with the addition of Conawapa to the Manitoba system. Mr. Cormie explained that:

> "Both parties have the right to terminate the sale if Manitoba Hydro does not commit to Conawapa by 2029. So it -- not only do we have the right to terminate the sale; they also have the right. If we're not prepared to build, Conawapa they have the right… it doesn't obligate us to build it. But if we do

> build it, they're -- we're obligated to deliver and they're obligated to take. But if we don't build it -- and this is -- this is new. If -- if we don't build it they have the option of cancelling the sale." (Tr. p. 2581, line 4).

8.3.6 Firm Export Contract Prices Benefit From Gas Price and Carbon Regulation Uncertainty

Not only is there presently a window of opportunity to build transmission in order to expand market access to Minnesota and Wisconsin, there is also an opportunity now to achieve premium prices for long term new hydraulic generation. Mr. Cormie has indicated that export customers are prepared to pay a premium for price certainty to hedge against factors such as natural gas price volatility and Manitoba Hydro's fixed price product monetizes that value. (Tr. p. 2563, line 8).

Mr. Wojczynski also testified that one of the biggest risks that the industry generally is facing is de-carbonization, moving away from coal and to a lesser degree, natural gas. This risk to most of the industry is conversely a benefit to Manitoba Hydro. He indicated three-quarters of the energy is thermal in the United States whereas Canada is 80% hydro. "--the utility industry in the US actually has become and is, in effect, an opportunity for Manitoba Hydro." In proceeding now with the export contracts Manitoba Hydro is taking advantage of the need for US customers to transform a portion of their generation fleets to a non-emitting technology at attractive long term firm prices for the firm hydro product. (Tr. p. 2568, line 7).

A more detailed discussion on export contract pricing can be found in Section 9.1.2 of this Final Argument.

8.3.7 Benefits of Plans with New Interconnection May Go Up

In the economic analyses of plans involving the 750 MW transmission line interconnection (assuming no Wisconsin Public Service investment) Manitoba Hydro assumed that it would be responsible for its share of the costs of the Great Northern Transmission Line for its full economic life. However, as Mr. Cormie has indicated permanent ownership is not Manitoba Hydro's goal and Manitoba Hydro is pursuing discussions to divest the line to others:

> "As a result, Manitoba Hydro's ownership is only as a last resort, but it is necessary to ensure that the large line is built and can be put into service by 2020. Manitoba Hydro is in ongoing discussions with other US transmission owners at this time who are interested in assuming Manitoba Hydro's 49

> percent investment and ownership position. We need to give Minnesota Power the assurance that the path that they're following will result in having the line costs paid for. Manitoba Hydro has made that assurance, but we expect that we will be able to transfer that responsibility to another US transmission owner. In the meantime, the line can proceed. So we are there as an owner of last resort." (Tr. p. 1327, line 1).

Manitoba Hydro is in active discussions with a US transmission owner who is keenly interested in investing in Manitoba Hydro's share of the GNTL (Tr. 2295). If such negotiations are successful, the long term costs assumed in the economic analyses associated with plans involving the 750 could be significantly reduced.

In addition to reducing costs by divesting ownership, the Great Northern Transmission Line will provide benefits from increasing Manitoba Hydro's ability to sell to more customers in Wisconsin. Mr. Cormie states "we've doubled the size of our market by having market access into Wisconsin. That – that optionality – the value of that optionality is – is huge because it will benefit Manitoba Hydro forever". (Tr. p. 2428, line 11). The value of having increased competition as a result of expanded market access into Wisconsin has not been reflected in the export prices used in the NFAT economic analysis.

8.4 The Future Role of Seasonal Diversity Agreements

Seasonal diversity contracts play an important role in Manitoba Hydro's resource plan providing capacity during Manitoba's winter peak season, and justifying the preservation of firm transmission service for exports and imports. Seasonal diversity contracts have the effect of reducing the need for Manitoba Hydro to build for capacity in the winter, but in exchange they increase the need for capacity resources in the summer to meet the export customer's summer peak load. Manitoba Hydro has looked at both increasing the quantity of seasonal diversity arrangements as well as extending the term of seasonal diversity contracts out into the future.

As indicated in MH Exhibit #195, there is significant uncertainty in the future in the difference between Manitoba's seasonal load peaks especially given the potential impact of proposed DSM programs to reduce electrical heating load over the winter peak. As a result there may be only a limited opportunity for significantly more Seasonal Diversity contracts than the 550 MW already under contract with Northern States Power and Great River Energy.

Extending the term of the existing seasonal diversity contracts beyond their current termination dates would not defer the need for new resources in Manitoba. As indicated in MH Exhibit #195, Manitoba Hydro needs additional energy resources before it needs additional capacity, so assuming the seasonal diversity sales contracts could be extended is of limited value in deferring the timing of new generation. Mr. Cormie explained "because we are generally building for energy and capac -- our capacity lags behind, freeing up additional capacity would just -- would just defer the need to build for our capacity to an even later date. So because we're building for energy, you know, there -- there are reliability benefits, but we are building because of energy, not necessarily for capacity under the -- under the Hydro scenarios." (Tr. p. 1339, line 3).

For the purpose of long-term planning, Manitoba Hydro does not include an extension of diversity agreements in the supply and demand tables unless they are signed or are in negotiation related to a signed Term Sheet. This is because Manitoba Hydro has no indication whether counterparties will or will not extend these agreements.

In the future, Manitoba Hydro expects the seasonal diversity contracts to attract additional value and has considered extending them, but only as a part of a package of long-term firm power products that will be available from Conawapa and not just strictly as seasonal capacity exchanges. (Tr. p. 4731, line 14). By way of example, Mr. Cormie described discussions with Great River Energy regarding up to 600 megawatts of power and additional seasonal diversity power to meet their needs post-2025 and confirmed that these sales would be subject to Keeyask/Conawapa and the new interconnection" (Tr. p. 1313, line 3).

It was also suggested that because there was no capacity charge associated with the summer capacity sale that Manitoba Hydro was not receiving value from its capacity exchanges. When cross-examined, Drs. Patton and Sinclair of Potomac Economics confirmed that money did not have to be exchanged for there to be value in seasonal capacity exchange agreements (Tr. p. 4729, line 14).

8.5 Hypothetical Development Plans

A number of development plans have been identified by Manitoba Hydro as being hypothetical plans due either to a change in circumstances (Plans with a 250MW US Interconnection) or due to infeasible assumptions associated with the LCA No New Generation plan. In addition, the PUB explored the potential that Manitoba Hydro could proceed with additional DSM, the new interconnection, and defer Keeyask until a later date.[83]

8.5.1 Plans with a 250 MW US Interconnection

Manitoba Hydro presented three alternative development plans in Chapter 8 of the NFAT Business Case which include a US interconnection with 250MW of export and 50MW of import: Plan 4 (K19/Gas24/250MW), Plan 11 (K19/C31/250MW) and Plan 13 (K19/C25/250MW).

These plans with a 250 MW interconnection are now considered hypothetical from a business perspective and as such can no longer be considered as viable alternative development plans. From a business perspective, a 250 MW interconnection would require renegotiation with Minnesota Power which would not be expected to result in the same level of benefits to Manitoba Hydro given that the entire economic analysis is now in the public forum. Further, MP has taken the position in its October Certificate of Need filing (Section 7.4.2.1, page 77) that "such a project would not meet the long-term needs of the region and would not prove to be cost-effective for customers or environmentally preferable over the long-term." The 250 MW interconnection is not likely to be approved by US authorities and proceed.[84]

Further discussion on the reasons that the 250 MW interconnection is no longer a viable option can be found in Section 8.3.2.

8.5.2 LCA No New Generation Plan

La Capra has proposed a development plan that attempts to defer new generation for as long as possible. The development plan includes increased DSM and fuel switching, extending the existing diversity sales to 2047, a new 750 MW import line and relaxation of the import criteria to allow up to 20% of Manitoba Load to rely on import energy. (LCA Exhibit #45, Slide 29).

The LCA No New Generation plan is not feasible. This plan included "expanded transmission for import" (Tr. p. 5609, line 13). La Capra testified that "...we wanted to test to see what would happen if -- if you increased the import limits on this. For purposes of this

[83] TR page 9890-9891, 9894
[84] Manitoba Hydro Exhibit 104-15 (Revision 2)

analysis, basically the parameters of the 750 line – to Minnesota was – was that was represented in this case (Tr. p. 5609, lines 18-22).

Manitoba Hydro noted in its Rebuttal Evidence (page 93, lines 8-12) that an import-only line was not feasible from Minnesota referring to the Winthrop and Weinstine Report attached as Schedule 1 to MH Exhibit #85. Mr. Swanson states, "… multiple statutory, regulatory and other factors would almost certainly prevent the certification, construction or operation of such an Import Line. Further, the Minnesota Public Utilities Commission (MPUC) has already found that new transmission must be constructed to facilitate the export of power from Manitoba to Minnesota. In short, an Import Line has no viability and does not offer a reasonable alternative for meeting Manitoba's firm supply needs going forward."[85] The report confirms that including a transmission interconnection intended primarily for import is not a feasible as an element in a development plan for Manitoba Hydro.

In response, Mr. Peaco suggested that an import line from other neighbouring jurisdictions should have been considered in Manitoba Hydro's analysis. "…if you are really of the mindset, I'm going to build transmission for import, you would probably look to a different point than you would if you were building a transmission line for export." (Tr. p. 5630, line 1). On cross examination, Manitoba Hydro reviewed the supply situation in North Dakota, Saskatchewan and Ontario wherein Mr. Peaco conceded that these markets are short of energy and not in a surplus position capable of supplying Manitoba (Tr. p. 6210-6214).

Although building a transmission interconnection primarily for import is not a feasible supply option, the 750 MW interconnection assumed in Manitoba Hydro's development plans provides increased import capabilities. It appears that La Capra did not recognize that Manitoba Hydro's development plans with a new 750 MW interconnection were in fact benefitting from the 750 MW of import capability from the new interconnection. Although Mr. Peaco stated (Tr. p. 5596, line 9) "There was – there was nothing really in any of the fifteen (15) plans that looked at increased imports," he went on to acknowledge that Manitoba Hydro did in fact increase imports in plans with a new interconnection. Mr. Peaco noted "In the dry years, the Preferred Development Plan is importing and that was not something that we'd really sort of thought of before." (Tr. p. 5628, line 3). The benefits of increased imports from a new interconnection have been a fundamental driver of Manitoba Hydro's development plans as described in Chapter 5 of the NFAT Submission.

[85] MH Exhibit #85 - Schedule 1, pages 2-3.

8.5.3 Plan with 750MW US Interconnection and Export Sales with Keeyask Deferred

Board Counsel explored the notion that Manitoba Hydro could proceed with additional DSM and the new interconnection to fulfill the MP 250 Sale, and defer Keeyask until a later date.[86] This notion is not feasible and should not be considered. The 750 MW interconnection will not proceed without Keeyask. As explained by Mr. Cormie, "It has been clear since we began negotiations with Minnesota Power back in 2007 that there needed to be a package, a package of new generation associated with new transmission. And that's what is necessary in order to have the interconnection built."[87] As explained in MH Exhibit #201, Manitoba Hydro and Minnesota Power share the understanding that if construction of Keeyask does not commence by June 1, 2016, the Agreement will terminate and no interconnection will be built. The response also indicates that additional DSM would not be an acceptable alternative to Minnesota Power as increased DSM does not provide new wind synergy benefits associated with the construction of new hydraulic generation. The response also states that it is Manitoba Hydro's view that regulatory approval of Minnesota Power's Certificate of Need filing is at significant risk if Keeyask does not proceed.

8.6 Development Plan Optimization

La Capra criticized Manitoba Hydro's development plan optimization from two aspects: optimization of the all gas plan for comparison purposes and optimization of resource options within development plans.[88]

In Manitoba Hydro's response to PUB/MH I-171, an explanation of the process used to optimize natural gas-fired resources in development plans was provided. The All Gas plan, which consists of a mix of combined cycle and simple cycle gas turbines, was optimized using firm capacity and dependable energy to meet Manitoba Load and existing contracts, and selling opportunity energy on the export market. Manitoba Hydro maintains that the All Gas plan was optimal or near optimal, and suitable for use in analyzing development plans. As explained in Section 8.1 above, an all CCGT Plan was evaluated and was demonstrated to be more costly than the Manitoba Hydro optimized All Gas Plan.

With respect to the optimization of resource options within development plans, judgment and experience in operating and planning a predominantly hydro system, together with

[86] TR page 9890-9891, 9894
[87] Tr. p. 9892 Line 5
[88] La Capra Initial Expert Analysis Report, Page 6 and La Capra Technical Appendix 3A, pages 3A-23.

information from past planning studies and economic evaluations allows Manitoba Hydro to develop representative sets of development plans for inclusion in studies. It is not necessary to analyze every possible combination of generation resource options using every possible in service date to provide meaningful information to decision-makers.

La Capra states (Technical Appendix 3A, Page 3A-20), that Manitoba Hydro's "process lacks quantitative optimization that is typically used by utilities in resource planning. Internal or third party model software (such as Ventyx Strategist) offer resource planning tools that optimize resource build out given a set of inputs." Manitoba Hydro responded to this comment in its rebuttal evidence, where Dr. Borison states "there is few, if any, third party resource planning tools (including Strategist) that are capable of true automated optimization under uncertainty."[89]

Further to this, when asked by the Chairman "How do you optimize – how do you do that before proceeding with the quilt and so on?"[90] Mr. Peaco responds as follows:

> "Well you know, it-it-having said that – it is a challenge. I mean, the limitations with Hydro and doing this analysis of – are – are real, because their – their modeling system, their – their physical generating system is very complicated. Their modeling system is very complicated, and it is very difficult the – for them to turn around – to postulate cases and turn around analyses on those until you can have those.
>
> So they have – they're – they're situated in a case where they – they are only able to do a few postulated tests. You know, in more simple models where you can – you can hit "go" on a computer, and it can generate thousands of alternatives, and you can get data from that, and – and look at that in a more efficient time frame, and that really isn't practical for the – for the modeling system that they're currently working with.
>
> And so the – part of the commentary here is simply an observation, is they – they aren't really in a position to test a limited set of options."[91]

[90] Transcript page 5648, line 6.
[91] Transcript pages 5648-5649.

Manitoba Hydro submits that it undertakes a focused level of optimization in its resource planning process and in the development plans that is appropriate for a meaningful and robust evaluation.

8.7 Manitoba Hydro Resource Planning is driven by Metrics

Manitoba Hydro has, in Chapter 8, Section 8.2 of the NFAT Business Case, detailed its process for establishing the development plans to be studied. CAC suggested in its closing submission that Manitoba Hydro perhaps "believes too deeply" in its plans. Mr. Wojczynski (Tr. p. 3696) addressed the notion that Hydro staff were "too invested" in the Preferred Development Plan. He testified that:

> "…people from Hydro, a lot of them, including myself, we're talking about engineers and accountants, … and MBAs, we're driven by metrics, customer reliability, security, our economics, the financial, the social benefit cost, metrics on environment and socioeconomic. We don't just do something because we happened to have been doing it in the past and want to carry on."

Mr. Wojczynski discussed examples where Hydro has indeed demonstrated that its decisions are made on the basis of objective criteria. Manitoba Hydro's direct evidence (MH Exhibit #129-7, Slide 11) includes a series of examples where, on account of changing circumstances, Manitoba Hydro has adjusted its decisions. These examples include the construction of Limestone which was commenced and then halted for over 10 years before it was built. Conawapa had previously been a committed project with PUB approval and signed contracts with Ontario and was subsequently cancelled. The Pointe du Bois powerhouse replacement project was cancelled and only the dam replaced when it became apparent that the economics did not support replacement of the powerhouse. Manitoba Hydro has also included combustion turbines and wind in its resources when it was economically feasible to do so. The GRE Diversity Exchange agreement has been extended, and DSM has been increased. Significantly, when new capital cost information became available in February, the PDP was taken back to the Manitoba Hydro Electric Board for their review and consideration as to whether Manitoba Hydro should continue to proceed with the Preferred Development Plan. These examples demonstrate Manitoba Hydro's ongoing commitment to making sound decisions based on the appropriate metrics, and suggestions to the contrary are unsupported by the evidence.

9.0 ENERGY PRICE FORECASTS

9.1 Electricity Export Price Forecast

9.1.1 Forecasting Methodology

Manitoba Hydro employs a consensus forecasting methodology whereby a number of independent experts are engaged to ensure that the corporation captures a broad range of perspectives on the future of electricity prices in the US upper Midwest.

The consultants are required to produce and justify their own assumptions independently to best represent the market as noted in the response to PUB/MH I-56a (lines 13-22). Manitoba Hydro does not provide direction to the consultants in their representation/modeling of the key input assumptions associated with their outlook of electricity prices.

The assumptions used by the consultants are based on the most up-to-date information available at the time the forecast is being prepared. The consultants apply their expert judgment to make reasonable assertions for inputs into their forecasting models. As the forecast is done on an annual basis, the consultants have the opportunity to continually update these assumptions as the market evolves and more clarity is gained on key issues such as domestic natural gas resources, coal retirements, carbon pricing and emission policies.

9.1.1.1 Consensus Forecasting is Appropriate

As described in Manitoba Hydro's Rebuttal Evidence (MH Exhibit #85 Section 8.1.2), consensus forecasting has been validated by a number of different economists, statisticians and other academics as a robust approach to reducing forecasting error over use of a single forecast.

From Manitoba Hydro's perspective, the consensus approach to forecasting, which aggregates a suite of independent market price forecasts, provides a number of benefits over using a single expert forecast. These benefits are outlined as follows:

- Ensures a wide range of future outlooks are considered, capturing both bearish and bullish views of future export price trajectories providing a more diverse set of perspectives of the future.
- Avoids utilizing a single view that may be overly optimistic or pessimistic relative to other market participants; using either extreme would result in a biased analysis.

- Dampens the effect of a significant change in a single consultant input assumption.

It should be noted that the use of consensus forecasting was acknowledged to be consistent with the approach used by other generators in North America by Potomac. (Tr. p. 4623, lines 6-14). Further, when questioned by the Chairman on what other approaches are employed (if not the use of outside experts), Dr. Sinclair was unable to cite any examples of alternative methodologies (Tr. p. 4624, lines 1-11).

9.1.1.2 Manitoba Hydro Uses Well-Established, Reputable Consulting Firms That Have Expertise in This Field

Manitoba Hydro's 2013 consensus forecast aggregated six independent price forecasts. The external price forecasting consulting firms Manitoba Hydro engages are recognized experts in their field who utilize sophisticated methodologies and software tools. This includes formal production costing models which simulate actual market dispatch characteristics and capacity expansion methodology that calculates the value of capacity price using a Net Cost of New Entry (Net Cone) analysis. All six external consultants used in the 2013 price forecast, are well-regarded, reputable, and highly active throughout North America in providing expert advice to the electricity industry on regulatory, financial and technical issues. Documents summarizing the demonstrated expertise of each of the 2013 price forecast consultants were provided in MH CSI Exhibit #16.

During their NFAT testimony, Potomac Economics agreed with the characterization that all six consultants used by Manitoba Hydro are well-established and reputable firms within the energy industry during their NFAT testimony (CSI Tr. p. 599, lines 12-15).

9.1.1.3 Adjustments Made By Manitoba Hydro in the Export Price Forecasting Process Are Appropriate

In the electricity export price forecasting process Manitoba Hydro makes adjustments to account for congestion and losses, to apply appropriate pricing premiums and to extend the forecast to the end of the detailed planning horizon.

<u>Accounting for Congestion and Losses</u>

Manitoba Hydro acknowledges the presence of transmission congestion between Northwest MISO and the rest of the MISO region. Manitoba Hydro's response to CAC/MH I-31 provides some context on the level of historical pricing divergence between the Minnesota hub and other major commercial hubs in the region. As noted in the response to CAC/MH I-32a, Manitoba Hydro accounts for congestion and losses by requiring external consultants provide a forecast for prices based at the Minnesota hub locational pricing node. This Minnesota hub price already captures congestion and losses between other Minnesota hubs and the MISO system. Potomac agreed with this description (Tr. p. 4588, line 25), and confirmed that Manitoba Hydro would only need to account for congestion and losses between the Minnesota Hub and the Manitoba border in adjusting its forecast (Tr. p. 4589, lines 8-11).

Manitoba Hydro documents the congestion and losses factor it applies to adjusted prices between the Minnesota hub and the border in Appendix E of the 2013 Electricity Export Price Forecast report as noted in the response to CAC/MH I - 75a. Neither Potomac nor La Capra noted it as an area of concern during the NFAT. Potomac's testimony (Tr. p. 4589, lines 17-20) acknowledges that Manitoba Hydro applies a factor for congestion and losses. La Capra comments in their report (Technical Appendix 6, page 6-69), with reference to Potomac's evidence on congestion, that "Potomac Economics has performed an analysis of future MISO congestion and losses. ... Potomac Economics' forecast of MISO prices is also done on an annual basis, and so does not provide a lot of insight into seasonal pattern changes, but its assumptions and methods do not seem inconsistent with MH's."

Initial concerns raised by Dr. Gotham in his report related to congestion and losses were satisfied based on his response to PUB/CAC-Gotham-1 "La Capra does indicate that MH did adjust for forecast congestion."

On-Peak Long-Term Dependable Price

Manitoba Hydro applies a [redacted] premium to the bundled On-Peak Energy & Capacity forecasts to produce an On-Peak Long-Term Dependable product price forecast. This Long-Term Dependable price is applied to bilateral on-peak (5 x 16) energy and capacity sales. The premium recognizes additional value such factors as price certainty, reliability and the virtually carbon-free attributes of the product provide to Manitoba Hydro's counterparties.

Support for the [redacted] premium is provided in Manitoba Hydro's CSI response to LCA/MH I- 433. In the response, contract revenues for long-term dependable export contracts are compared to forecasted values for the same product, inclusive of the [redacted] premium. The analysis indicates that for contracts signed since 2005, the average price negotiated for the On-Peak component of the sales are [redacted] of the Long Term Dependable forecast price, or [redacted].

This analysis supports the assumption that Manitoba Hydro can achieve a [redacted] premium, [redacted] on long-term dependable sales over the base market forecast. This has held true since 2005, a period encompassing both high and depressed energy price environments (i.e. pre and post 2008 economic downturn).

On-Peak Opportunity Revenue

Appendix 9.3 of the NFAT Submission outlines Manitoba Hydro's price forecast products. For those plans that have exportable hydro-electric dependable energy, this product is assumed to be sold under firm contract(s) at the On-Peak Long-Term Dependable Price. Other surplus dependable energy is assumed to be sold into the export market when it is economic to do so and is valued at the on-peak opportunity price or off-peak opportunity price.

As discussed in Manitoba Hydro's response to PUB/MH I-013c, surplus dependable energy other than hydro-electric energy is not assumed to be sold under firm contract(s) as Manitoba Hydro is at a competitive disadvantage when the same resources can be built in the MISO market due to transmission losses between Manitoba and major MISO load centers such as Minneapolis.

On-peak opportunity energy is assumed to be sold at the on-peak energy price [redacted]. This [redacted] pricing takes into account on-peak day ahead energy sales as well as accounting for the additional revenue realized through sales activities which take place within the one year time frame. Sales activities include firm energy and capacity sales, forward energy sales and other sources of revenue from the export market. Manitoba Hydro's response to LCA/MH II- 471b provides an analysis which supports the pricing of on-peak exports at the on-peak energy price [redacted].

Off-peak opportunity energy is assumed to be sold at the off-peak energy price.

Extrapolation Methodology

Section 1.5.1 of NFAT Appendix 9.3 (page 9) notes that external price forecast consultants normally produce a market forecast for a 20-year period. Starting with the 2013/14 forecast, Manitoba Hydro has established a process to extrapolate the consensus forecast beyond 20 years to the end of the 35 year detailed study timeframe. The extrapolation results in reducing the annual growth rate to 0% by 2047 in a linear fashion.

This extrapolation methodology produced lower than historical growth rates for the final 15 years of the forecast when compared to previous forecast vintages (when consultants provided a full 35 years of data). The applied extrapolation methodology therefore produces more conservative results as can be seen in Appendix A of the 2013 Electricity Export Price Forecast report (provided CSI).

In Section IV in their report[92], Potomac Economics did not take exception to this methodology, although they do surmise that running a 0%/year real escalation rate "sensitivity" might provide some additional insight.

During the NFAT hearing, Potomac did acknowledge that the growth rate Manitoba Hydro applies is "not a very large rate" and "it declines very quickly and is zero after that" (Tr. p. 4463, lines 12-14). As a result, this would lead to the conclusion that it likely would not have a major impact in the economic analysis. Further to the question of the appropriateness of Manitoba Hydro's calculation, Mr. Sinclair stated "... But we don't have a -- we don't -- we don't see that growth rate as being a particular problem as far as the impact on the overall analysis."[93]

Potomac admits that (Tr. p. 4592, lines 22-25) it is unlikely that a significant drop in the growth rate would occur in years immediately following the end of the 20 year forecast. Manitoba Hydro's methodology captures the drivers influencing growth at the end of the 20 year period, and thereafter reduces the annual growth rate quickly in the following years. As a result, Manitoba Hydro submits that its extrapolation methodology is reasonable and appropriate.

9.1.1.4 Potomac Improperly Dismissed Consultant Forecasts

Potomac notes that their access to consultant models', assumptions and inputs was limited. "At the outset, we note that detailed info regarding each of the consultants' models, assumption and output was limited. We generally only received high-level representations of the models and inputs. This limited our ability to critically review the consultants' results and ultimately compelled us to produce our own forecast"[94]. Manitoba Hydro notes that

[92] Potomac Economics Report – Section IV, page 45.
[93] Transcript page 4707.
[94] Potomac IEC report, page 10 – 2nd paragraph.

Potomac's scope of work explicitly required them to produce a comparable electricity and gas price forecast to compare against Manitoba Hydro's benchmarks[95]. Potomac's evidence in this regard was that they expected to be able to use more of the independent forecasters underlying assumptions and get an understanding of the underlying models and then from that develop a forecast. (Tr. p. 4557)

This expectation ignores the fact that price forecast consultant models and the underlying methodology is extremely proprietary and closely guarded as commercially sensitive information and corporate trade secrets. In fact even the output and content of the forecast reports are confidential and were only released in the PUB CSI process after written assurances that they would be subject to confidentiality agreements. It is an unrealistic expectation that Potomac Economics, who can be characterized as a market competitor to other energy analyst firms, would be granted open and unfettered access to rigorously review, assess and test the inner most details of the production costing models used by Manitoba Hydro's price forecast consultants. Potomac Economics agreed that due to the high value of these price forecast reports, the consultants have strong business motivation for wanting to protect their information (CSI Tr. p. 600, lines 16-21).

Potomac's Scope of Work required that Potomac assess Manitoba Hydro's export price forecast methodology as it related to the NFAT analysis. To support the Potomac analysis, Manitoba Hydro provided unfettered and complete access to the content of the price forecast consultants' forecast reports as well as Manitoba Hydro's own analysis files and full methodology utilized in producing its annual Electricity Export Price Forecast report. During the NFAT hearing Potomac did acknowledge that they believed Manitoba Hydro had turned over all internal documentation the corporation had in its possession related to the production of the export price forecast. (Tr. p. 4563 lines 1-11)

Potomac reviewed all of Manitoba Hydro's documentation and did not raise any objections to the methodologies employed by the corporation in the 2012 Adjusted and 2013 price forecasts. However, Potomac chose to summarily dismiss each of the six independent price forecast consultant reports used to produce the 2013 electricity price forecast, on the basis they did not find them to be credible because Potomac was unable to access the price forecast consultant models and the output of the those models. (Potomac Economics report, Section III-C)

Manitoba Hydro submits that it is not reasonable to dismiss the prices of the six independent

[95] Potomac Scope of Work - clause 12 states *"Provide a comparable natural gas price and MISO electricity market price history and forecast over 20/40/80 years."*.

industry experts, acknowledged by Potomac as well-established and reputable,[96] simply because they differ from Potomac's results. Potomac Economics itself acknowledged that the EIA input assumptions they relied upon to create the Potomac export price forecast were subject to this same uncertainty (Tr. p. 4566, lines 23-25 and Tr. p. 4567, lines 1-6). Long-term forecasting has an inherent level of uncertainty associated with it and no private or public entity has any special ability to predict the future.

9.1.1.5 Manitoba Hydro's Electricity Export Price Forecast Is Reasonable for Long-Term Planning

Manitoba Hydro's Electricity Export Price Forecast report provides a 35-year forecast of electricity prices in the upper Midwest region of the United States, a long forecast period relative to industry standards; however one that is necessary due to the long life of hydraulic generating facilities.

In Section 8.1.3 of Manitoba Hydro's Rebuttal Evidence (MH Exhibit #85), the Corporation provided evidence demonstrating that Potomac's price forecast is within the range of individual outlooks received from external price forecast consultants in 2013, although it was acknowledged that Potomac's forecast is somewhat [redacted] than the average view considered. Manitoba Hydro considers Potomac's price forecast to be another reasonable view of the future, however it is just one single view, and as such it should be provided no more or less weight than other independent outlooks considered by Manitoba Hydro.

Manitoba Hydro recognizes that there is uncertainty in the long-term forecasting of any economic variable or commodity and further that forecasting these variables is complex, largely due to the sheer number of assumptions involved. Manitoba Hydro also recognizes that, among experts, there is generally no ability for one expert to predict the future better than another. Potomac Economics acknowledged this (Tr. p. 4579, lines 16-18) when Mr. Sinclair stated "I mean, there's better experts than others, but there can be legitimate disagreements about how to proceed".

9.1.2 Contract Prices Support Manitoba Hydro's Electricity Export Price Forecast

There have been a number of long-term bilateral contracts signed recently between Manitoba Hydro and US counterparties that can be used to gain insight into the reasonableness of the Electricity Export Price forecast. These signed contracts represent agreements between

[96] CSI Transcript Page 599, lines 12-15.

sophisticated market participants agreeing on a set price for energy and capacity resources to be delivered during the horizon of the price forecast. If Manitoba Hydro's price forecast was [redacted], it would be very unlikely that agreements would be reached with US counterparties. However, if these contract prices are favourable, it should be a strong indication that the Corporation's price forecast is reasonable [redacted].

The chart below was provided in Manitoba Hydro's direct evidence – CSI Exhibit #1. It compares a number of relevant pricing points to determine how current market expectations relate to Manitoba Hydro's and Potomac's 2013 price forecasts:

- The Potomac's Reference Case <u>(with carbon)</u> price forecast for an On-Peak bundled energy & capacity product
- Manitoba Hydro's price forecast for its Long-Term Dependable product (On-Peak energy & capacity product + [redacted] premium)
- Recent long term firm sales signed by Manitoba Hydro

[redacted]

The chart above demonstrates that the recently signed contracts [redacted] Manitoba Hydro's long-term dependable price forecast, providing confidence that Manitoba Hydro's electricity export price forecast is reasonable [redacted] for the purpose of long-term resource planning.

These contracts compare [redacted] to Potomac's Reference Case price forecast. It should be noted this is Potomac's Reference Case forecast with the full value of MNP's carbon price, not a weighted probability of the two reference cases (carbon and no carbon). Using a weighted average of Potomac's two Reference Cases would show an [redacted] between realized contract prices and Potomac's forecast.

This demonstrates the reasonableness of Manitoba Hydro's electricity export price forecasts for long-term planning and casts doubt on Potomac's assessment that the consultant prices and Manitoba Hydro's forecast [redacted]. Although this analysis does not speak to the eventual accuracy of either the Manitoba Hydro or Potomac forecasts, it does provide confidence that Manitoba Hydro is [redacted] in its outlook of future electricity export prices.

9.1.3 MISO Prices Will Increase under Low Load Growth

The question of the impact of a reduction in load growth on electricity prices in the MISO market was raised during the NFAT hearings by Elanchus' Mr. Todd. The essence of Mr. Todd's evidence is that conventional economic theory would suggest that, all other factors being equal, a reduction in load growth would put downward pressure on electricity prices. (Tr. p. 4926, lines 19-23). Mr. Todd also notes that without modeling the effect, it is impossible to quantify the impact of assuming load growth in MISO is flat.

All six of the expert industry market consultants used by Manitoba Hydro in the preparation of the electricity export price forecast incorporated small positive load growth in the 2013 price forecast. Potomac Economics relied on annual load growth figures from the EIA's 2013 Annual Energy Outlook (Potomac Report, Section II – 5a). EIA outlooks for annual load growth for the Midwest US are also around 0.5%/year. The effect of projected annual load growth estimates are captured in the export price forecasts provided by the price forecast consultants used by Manitoba Hydro, Potomac Economics and in the EIA's retail electricity price forecast. While the annual load growth figures are relatively small, all of these entities expect consistent real price growth over the next twenty years.

Dr. Dean Murphy from the Brattle Group explained the relative impacts of load growth assumptions during the NFAT hearing (Tr. p. 1407-1409).

> "So I'll turn the page, and talk briefly about a couple of other factors that are, I think, a little less important than fuel costs and a potential CO2 price, and even coal plant retirements, but – but not unimportant. The first of these is load growth, and here I mean load growth in MISO. Growth has been quite low in the last five (5) to ten (10) years, particularly in the last five (5) years after the -- the recession. Load actually fell considerably, you know, around 2008, 2009, but the expectations are that we're not going to rebound to a 3 percent load growth rate, which we saw as of a few decades ago, but rather that load growth will continue on this very low -- at this low level of maybe 0.7 percent, less than 1 percent, or -- or maybe as much as 1 percent. And, so one of the reasons that I -- that I say that load growth is a less important factor for determining power prices in MISO is simply because it's not very uncertain. There's a general agreement that load growth will be low. Perhaps disagreement about whether it'll be 0.7 percent or 1.0 percent, but in the end, that makes very little difference to the supply/demand balance, and to energy prices.
>
> And so simply because there's relatively little uncertainty in load growth, I would -- I would argue that it will not make a big difference in power prices in MISO. It is swamped by other effects. In particular, coal plant retirements, because the – the coal plant retirements are -- if -- if MISO is right and they expect 12,000 megawatts of coal retirements, the difference between a 0.7 and a 1 percent load growth is three-tenths (3/10s) of a percent, so that's -- that's less than 1,000 megawatts of load growth. In fact, it might be a few hundred megawatts of load growth relative to thousands of megawatts of adjustment on the supply side. So -- so I don't think it's a – a terribly large effect."

As noted by Dr. Murphy, the supply side pressures in the medium term (which include US Environmental Protection Agency's emerging GHG regulations for coal and expiration of nuclear licences in the 2030's) (Tr. p. 1405, lines 12-20) effectively require new generation supply in MISO to meet load obligations, even under the assumption of very low or flat load growth. In addition, the evidence from the Brattle Group suggests that because of the characteristics of MISO's supply curve, changes in load growth assumptions are not a primary driver of power prices.[97]

[97] NFAT Appendix 5.3, page 66.

The muted impact of MISO load growth assumptions on long-term electricity prices is also explicitly addressed by the Brattle Group in other documents provided as evidence during the NFAT process.[98]

9.1.3.1 Interrelationship of Supply Side Resources and Load Growth

As described in Appendix 5.2 of the NFAT submission, under a competitive market structure, the absolute level of electric load determines which units are dispatched in any specific hour. The electric load in effect determines what resources "clear" an energy auction and the prices that are paid to the generators being run to serve that load. To model future prices, assumptions of the change in regional load must be made, along with a number of other assumptions that will affect the generation supply stack for the region. Examples are provided in Appendix 5.2 of the NFAT submission and in the Potomac Economics' report, Section II. B. 3 Formation of Supply Curves, which illustrate how energy prices are affected by both supply and demand.

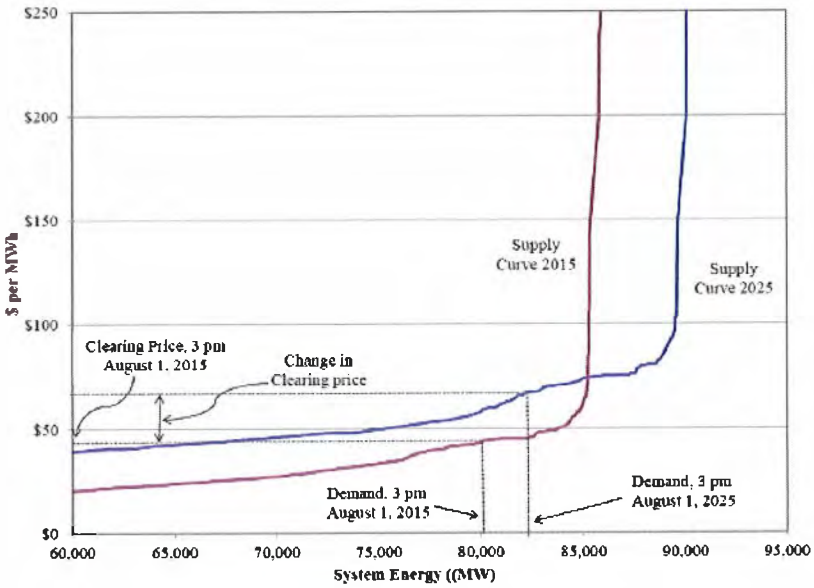
Due to the interrelationship of these factors, the impact of load growth must be thought of from a more holistic perspective in the context of other factors that affect price. In Section II: B - 3 of their report, Potomac Economics provides a useful summary of these key factors in their discussion of the creation of future supply curves.

> "If all key supply variable remain fixed, then the forecast of each future hour would be identical to the base historical hours from 2011-2012. However, of course, key variables change. In particular, we create new supply curves for each hour based on projections of (1) fuel prices, (2) additional and retirements of generating capacity; (3) load growth; and (4) carbon taxes."

These factors are considered in Figure 10 in Section II: B – 3 of Potomac Economics' report (provided below) which illustrates two anticipated supply curves, one for the year 2015 (red line) and the second for year 2025 (blue line). The change in supply curves in Figure 10 provides an illustrative tool as the effect electric load has on price is disaggregated from the other factors noted above.

98 Slide 52 in NFAT Appendix 3.1 (Long-Term Price Forecast for Manitoba Hydro's Export Region), Slide 72 of Manitoba Hydro's Panel 2 Direct Evidence Presentation, and Slide 66 of NFAT Appendix 5.3 (Electricity Market Overview for Manitoba Hydro's Export Market in MISO).

Figure 10: Example of Change in Supply Curve



Note: The figure shows the change in forecast clearing price in our model resulting from changes in supply and demand between 2015 and 2025.

In Potomac's Figure 10, demand is increased slightly from 80,000 MW in 2015 to around 82,000 MW in 2025 to account for load growth in a particular hour. As a result, price increases from approximately $45/MWh (relative to the red line) to approximately $70/MWh (relative to the blue line). Using an assumption that load growth was flat over that period (i.e. load remains at 80,000 MW in 2025), the chart illustrates that the market clearing price would still be higher than it was in 2015 due to factors other than load growth. At a demand of 80,000 MW the market clearing price in 2025 would be about $60/MWh under a flat load growth assumption. This is a markedly higher price than the (approximately) $45/MWh the market would clear at in 2015 under the same demand assumption.

This example illustrates that load (and subsequently load growth) can influence price; however, with MISO's relatively flat supply curve other factors can become the dominant influence on price. Even in a situation with no load growth and using Potomac Economics' Figure 10, prices would be expected to increase by over 30% by 2025 strictly due to non-load effects. The conclusion that load growth has a minor effect on price was also reached by the Brattle Group through their extensive modeling of the region.

9.1.3.2 Coal Retirements in MISO Relative to Expected Load Growth

As noted in the NFAT filing, MISO expects 12 GW of coal to be retired in the near term (i.e. by 2020) due to a confluence of emerging EPA regulations on mercury and due to moderate natural gas prices. These retirements represent almost 20% of MISO's total coal generating fleet. The effect of three separate load growth assumptions on coal retirements is presented in the table below.

	Cumulative GW by 2020	Net New Supply Needed due to Coal Retirements & Load Growth (GW)
MISO Coal Retirements	12	
Cumulative Load Growth (2014-2020)*		
1%/year	7	19
0.35%/year	3	15
0%/year	0	12

**% annual load growth is based on the base resource of 120 GW year used for illustrative purposes*

The table demonstrates that even under a 1%/year load growth estimate, coal retirements would still represent about two-thirds (12 GW of 19 GW) of the supply shortfall between now and 2020. This analysis does not capture other supply side retirements of other technologies such as oil and natural gas (end of life units). Although these technology retirements (to 2020) are not expected to be significant, they will add to the supply deficit for the region.

When considering nuclear generation, most potential retirements are not expected until the 2030 timeframe when extended licences are set to expire. When nuclear retirements do occur, they have a significant impact due to the large size of the generating units. Although load growth assumptions are an important input required to estimate the long-term electricity price for the MISO region, the impact of load growth in determining prices in relative terms is less important than key drivers such as fossil fuel prices, carbon pricing and expected changes to the generation fleet.

9.2 Carbon Pricing (MDB inserted May 19)

9.2.1 Carbon Price Assumptions are Reasonable

The carbon price assumptions embedded in the electricity price forecast are reasonable and prudent because they are:

- Consistent with climate change science and emerging policies
- Based on a sound consensus methodology
- Reflective of a comprehensive range of outcomes,
- Conservative

Future carbon pricing represents an important factor in the market price of electricity. While the timing and magnitude of policy responses are uncertain, there are broad expectations that the US electricity sector will experience carbon pricing within the next 10 years as climate or environmental policies evolve to address the physical realities of climate change (MH Exhibit #95, p.68). This view is supported by Dr. Murphy from The Brattle Group, "I expect that there will be a carbon price at some point in the future. I can't tell you exactly when that will happen. The --the inconvenient truth is that CO2 emissions do contribute to -- to climate change, and the planet will continue to remind us of that over time." (Tr. p. 1809, lines 11-16).

As detailed in Section 16 of this document, greenhouse gas (GHG) emissions are facing increasing constraints through federal regulations and state legislation in the United States. These policies will increase the demand for low and non-emitting resources and in many instances will deliver increasing market prices that will provide an incentive for these types of resources.

Environmental factors including carbon pricing policies are among many factors considered in developing the consensus electricity export price forecast. While the price forecast consultants provide the carbon values that have been assumed for each scenario, the consultants rely on their own perspective of the future to determine what, if any value for carbon will be included in their price forecast. In fact [redacted] six consultants in the 2013 electricity price forecast have a [redacted] for carbon in their reference case through the forecast horizon (MH CSI Exhibit #1, p. 14). The consensus approach results in forecasts that leverage the expertise and diversity of leading forecasters and moderates results by blending the perspectives equally.

There is a broad range of potential carbon pricing and climate policy outcomes. For example Brattle considered six CO2 price / climate policy scenarios in its electricity market price analysis (***Appendix 3.1 – Long-Term Price Forecast for Manitoba Hydro's Export Market in MISO - The Brattle Group***, Page 40). For Manitoba Hydro's Electricity Export Price Forecast, Brattle narrowed the range to three carbon pricing scenarios: low (no carbon pricing), base and high.

Reducing carbon pricing to a 50/50 split as discussed by MNP (Tr. p. 5469, lines 3-9) is an inappropriate oversimplification. A similar argument was presented by Dr. Gotham, saying of carbon pricing "It's on or off. It will happen or it doesn't happen" (Tr. p. 8562, lines 8-9). Future carbon policy is not a binary all or nothing situation but rather a continuum of potential outcomes all of which could have a variety of direct or indirect carbon pricing implications. The outcomes range from no climate policies or action, to a variety of non-pricing policy options to an array of pricing policy options and pathways (see MH Exhibit #95, p. 67). However given the policies that have been implemented in a number jurisdictions and which are under consideration elsewhere and the regulatory approach being aggressively pursued by the Obama administration, the potential for there to be absolutely no further climate change policies affecting electricity market prices is unlikely. [redacted] (including Brattle) in the 2013 electricity price forecast assume [redacted] in their reference case (MH CSI Exhibit #1, p. 14).

Dr. Gotham's carbon price views appear to be influenced by the political position of the former governor of Indiana (Page 8436, lines 9-15). Dr. Gotham offered an interpretation of carbon pricing "I think that the likelihood of the Midwest region imposing their own carbon restrictions is very small." (Page 8436, lines 3-5). However, it should be noted that in its Indiana applications Duke Energy includes a carbon price in its planning assumptions (MNP CSI Undertaking 30). While Dr. Gotham's view may or may not accurately reflect Indiana's current outlook, his view is not indicative of the whole Midwest region. In Minnesota, regulatory costs of carbon are expected. Minnesota requires utilities to include future cost of carbon regulations in the range of $9 to $34 per ton of carbon emitted in utility resource plans (MNP CSI Undertaking 30).

Even though it is unlikely that there will be absolutely no further climate change policies affecting electricity market prices, this possibility is fully considered by the electricity price forecasters in the 2013 low electricity export price forecast where all of the consultants assumed no carbon pricing.

As demonstrated in CSI MH Exhibit #1 the carbon pricing assumed in the reference case of the Manitoba Hydro export price forecast is [redacted] to the MNP's Reference Forecast. It is also [redacted] to the range of carbon price risks Minnesota generators are required to consider as described above. In the long run MH's consensus of carbon pricing assumed in the consensus export price forecast is [redacted] of MNP's reference case, (MNP CSI Undertaking #30, line 33). [redacted]

There would likely be [redacted] in the economic outcome between Manitoba Hydro's [redacted] and a 50/50 split between MNP's [redacted] base carbon pricing scenario and a no carbon price scenario. During the course of the NFAT, MNP and Manitoba Hydro came to a better understanding of each other's risk management approaches in dealing with carbon pricing assumptions. In its recent undertaking MNP concludes that MH's approach is analytically reasonable and acceptable and provides conservative results. (MNP CSI Undertaking #29.)

Even the highest carbon price forecasts considered during these proceedings are modest relative to the estimates of global carbon damages. MH Exhibit #185, p. 3 compares the assumed social cost of carbon with the carbon price forecasts prepared by MNP. As discussed in Section 18, for the range of policies under consideration today, a very significant portion of the total social cost of carbon is expected to remain an economic externality. Pressure over time will tend to push for stronger policies and this represents a significant additional upside opportunity for the development plans with more hydro development and high exports and a further downside risk for development plans reliant on natural gas generation. MNP indicates that carbon prices are expected to continue to grow past 2048 and it is not likely that prices will experience zero real growth at any point in the future. (MNP CSI Undertaking #29, lines 9-14)

In light of the existing and emerging energy policies, Manitoba Hydro's export customers are choosing or exploring the purchase of hydroelectricity in part as a hedge against future GHG emission constraints and to achieve future pricing certainty. Utilities in the US Midwest are aware that a strong reliance on emission intensive generation will likely be a future competitive disadvantage. Therefore corporate mandates have been adjusted to reduce their emission profile and in turn their carbon risk. Minnesota Power's Energy Forward strategy is an example of this shift in strategy (NFAT Chapter 6, page 15) from a coal dominated supply mix, to a diversified portfolio incorporating significant quantity of carbon free electricity. The potential of future carbon pricing in the electricity sector has already substantially affected the industry's approach to long-range planning, risk mitigation and strategic direction.

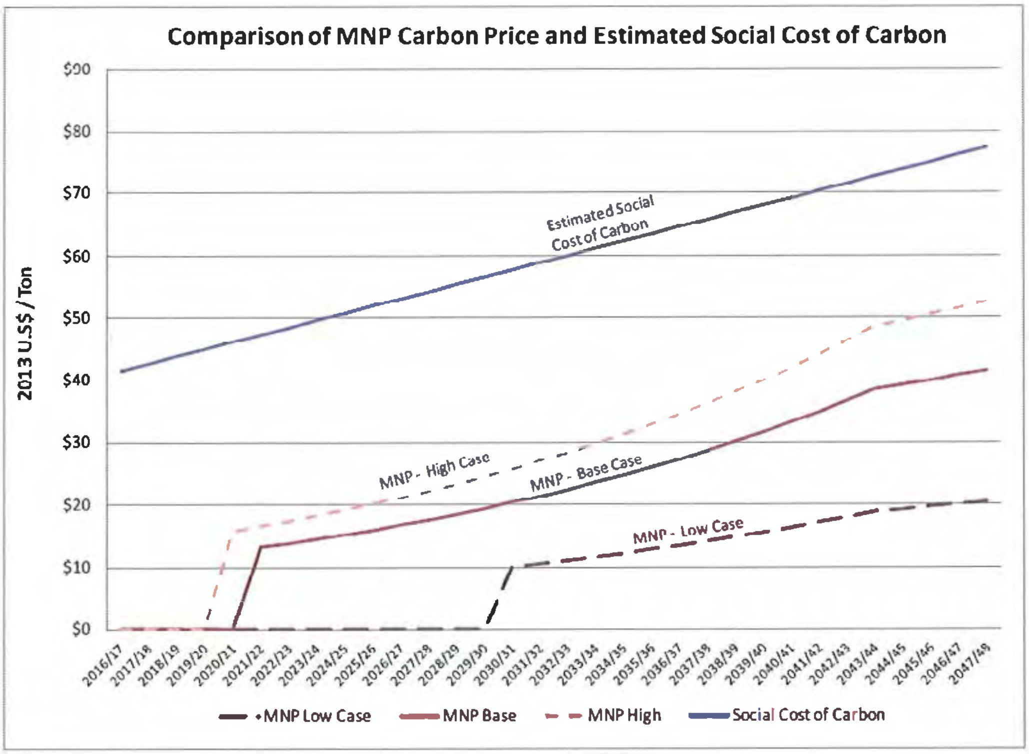
With Minnesota counterparties considering in their planning and decisions the potential cost of carbon, the value they are able to pay relative to other thermal resource options increases. [redacted]

[redacted] This indicates that these counterparties are willing to pay [redacted] Manitoba Hydro's reference electricity price that includes carbon pricing. This is also true for WPS even though Wisconsin doesn't have a formal state mandate to consider a carbon price.

9.2.2 Conclusion

The carbon price assumptions embedded in the electricity price forecast are reasonable and prudent. These assumptions are consistent with climate change science and emerging policies. They are based on a sound consensus based methodology that utilizes diverse independent expertise. The forecasts recognize a continuum of possible climate change policy outcomes and a range of implied or direct carbon prices (including the possibility of a zero carbon price). [redacted]. In the long term, consideration of externality costs associated with climate change damages may push policies and carbon market prices higher than current scenarios indicate offering additional potential export price benefits.

[redacted].



Source: MH Exhibit #185, page 3.

9.3 North American Natural Gas Price Uncertainty

Throughout these proceedings, there has been considerable focus on the risks associated with wholesale electricity prices, but little discussion of the risks related to natural gas prices. Dr. Murphy made reference to the speed in the turnaround from a gas-constrained future to one where gas is seen as abundant enough that LNG facilities that were originally built for importing LNG are now being converted for export (Tr. p. 1399-1400). Despite the abundance of technically recoverable natural gas resources in North America, prospects for future production from shale resources continue to be uncertain due to the lack of production history from many of the formations (Tr. p. 3695, lines 6-13). While future technology could increase well productivity and reduce the cost of production (this has been evident since the onset of the shale gas revolution), innovations could become stifled if local and/or national environmental concerns regarding fracking-related chemical use, seismic activity, and emissions become more widespread (Tr. p. 5169, lines 6-13).

The final end-use of this future production is also uncertain, particularly in some sectors. Residential and commercial consumption of natural gas are generally expected to remain flat due to end-use efficiency gains. Natural gas consumption in the electricity generation sector is expected to continue to increase as coal-fired power plants are either retrofitted or retired in order to comply with the requirements of the Mercury and Air Toxics Standards (MATS) (Tr. p. 1398-1399). Future regulation of carbon emissions has the potential to further increase the consumption of natural gas in this sector as well. The US industrial sector is experiencing significant increases in natural gas consumption as expansion in the chemicals industry continues.

There is a vast but uncertain potential for demand for natural gas in the transportation (Tr. p. 10205, lines 3-4) and LNG export sectors. Demand in the transportation sector is particularly difficult to predict because they are dependent not only on the future price of natural gas, but on the inter-relationship between the price of natural gas and the price of crude oil. If the large disparity between prices of the two commodities continues, the economics of conversion from oil-based fuels remains very attractive, particularly in the heavy-duty vehicle and railway sub-sectors.

Similarly, the potential for significant LNG exports is dependent upon the price differential between the North American market and export markets being large enough and sufficiently stable to justify the investment in export facilities (Tr. p. 1399-1400). There are also further complications regarding the approval of facilities to allow the export of a resource that some see as providing a key input for an industrial renaissance in the United States.

Like other commodities, there is fundamental uncertainty and volatility as to what the evolving equilibrium price will be in the natural gas market. Credible consideration of natural gas generation needs to account for the fact that there is risk uncertainty associated with natural gas prices.

10.0 ECONOMIC ANALYSIS

In the NFAT Business Case, Manitoba Hydro provided three major sets of analyses: economic, financial and multiple account. The economic analysis determines the investment value over the life of the longest lived assets and is integral to resource decisions. When evaluating and choosing among alternative development plans, the appropriate measure is the net present value or NPV of the incremental costs and benefits associated with one plan relative to another.

Manitoba Hydro has conducted a high quality economic uncertainty analysis that is fundamentally sound. Manitoba Hydro prepared the analysis for the NFAT business case with the guidance and support of Navigant Consulting, Inc. Dr. Adam Borison[99] of Navigant assisted Manitoba Hydro in developing its probabilistic analysis approach to evaluating the uncertainty associated with the development plans included in the NFAT submission.

As described in Dr. Borison's evidence[100], there are three major steps in uncertainty analysis:

- Formulation – deciding on the elements of the uncertainty analysis and their relationships
- Inputs – collecting and processing the data that goes into the uncertainty analysis
- Outputs – generating and interpreting the results that come out of the uncertainty analysis.

Manitoba Hydro's approach to all three of these steps is fundamentally sound and follows well-established analytical principles and relevant empirical evidence. It is in many ways "state-of-the-art" in utility resource planning. The high quality of this work should provide the panel with confidence that conclusions based on this analysis are on solid ground.

Sufficient economic analysis has been provided from the overall project perspective through the economic evaluations provided by Manitoba Hydro in Chapters 9, 10 and 12 of the NFAT submission and subsequently in Manitoba Hydro exhibits, particularly MH Exhibits #95, #104, #129-7 and #171. Economic analysis information is one of the primary building blocks for the financial, multiple account and optionality/pathways analyses.

[99] Schedule 3 of Rebuttal Evidence of Manitoba Hydro, MH Exhibit #85, p. 4.; Dr. Borison is an expert in decision analysis, economic and financial analysis, real options, optimization, risk analysis and related methods and has more than 25 years of consulting experience applying uncertainty analysis methods to investments and operations in electric power, oil/gas and biofuels.

[100] Schedule 3 of Rebuttal Evidence of Manitoba Hydro, MH Exhibit #85, page 6.

10.1 NFAT Analysis is Robust

The robustness of Manitoba Hydro's analysis is demonstrated through the provision of the major sets of analyses: economic, financial, multiple account, and optionality/pathways. This robustness is supported by MIPUG in Mr. Bowman's pre-filed testimony where he stated with respect to Manitoba Hydro's approach to analysis that the approach "is comprehensive, reasonable and more thorough than typically found in utility resource plan assessments."[101]

The economic analysis determines the investment value over the life of the longest lived assets. The financial evaluation focuses on the comparative impact on future customer rates and Manitoba Hydro's comparative exposure to financial risk. Affordability and the temporal distribution of costs and benefits are also addressed in the financial analysis. The multiple account benefit cost analysis takes into consideration consequences for Manitobans that are not reflected in the revenues and expenditures of Manitoba Hydro and provides a comprehensive assessment of all the benefits and costs to Manitobans to address the question of overall socio-economic benefit. The pathways analysis uses the economic evaluations as its basis and assesses the flexibility of options to allow for a change in course based on future conditions. The use of pathways recognizes the reality of allowing decisions to be made incrementally as uncertainties resolve.

La Capra criticized Manitoba Hydro for not providing numerous metrics in its economic analysis.[102] The metrics suggested by La Capra are only appropriate when undertaking financial analysis.[103] Despite the fact that Manitoba Hydro provided additional metrics in its financial analysis that reflect the timing of costs and benefits and the associated risks, La Capra paid no regard to this analysis and instead attempted to do this work through economic analysis using inappropriate metrics in its Appendices 9A and 9B.

Manitoba Hydro presented the sets of analyses – economic, financial, multiple account, and optionality/pathways – in separate chapters of the NFAT submission in order to compartmentalize the analysis to assist in the comprehension and utility of the discrete metrics that each of the sets of analyses provides. When all the analyses are taken together, the NFAT analysis is robust.

[101] Mr. Bowman's Pre-filed Testimony; pages 3-14.

[103] La Capra, Technical Appendix 9A, pages 9A-22.

10.2 Economic Analysis Assumptions and Methodology are Appropriate

As described in Chapter 9 of the NFAT Business Case, economic comparisons of alternatives are used to assist in making decisions regarding which resources to pursue and when. When evaluating and choosing among alternative development plans, the appropriate measure is the NPV of the incremental costs and benefits associated with one plan relative to another. The economic analysis determines the investment value over the life of the longest lived assets, while the financial evaluation provides the affordability and the temporal distribution of costs and benefits as well as the corporate financial indicators.

Manitoba Hydro uses standard economic analysis for project evaluation, known as NPV as explained in Chapter 9 NFAT Business Case[104]. This approach is supported by CACs witness Mr. Bill Harper[105] as well as by La Capra who commented "Present value analysis is a common approach for economic analysis of an investment in which annual costs and revenues are discounted to a common point in time or an equivalent comparative analysis."[106]

Incremental analysis is a relative perspective where the focus is on the differences between development plans rather than the absolute value of the costs and benefits of each development plan. As a result, it is more important for the incremental differences between the plans to reflect the components of the plans. For example, applying appropriate annual real escalation rates in the analysis to the capital costs of the different resource options of wind (0%), hydro (0.6%) and natural gas (0.5%), results in a meaningful comparison between plans that include these resource options, as described in Appendix 9.3 of the NFAT submission.

In La Capra's Economic Analysis Technical Appendix 9A, pages 9A-22 and 9A-49, are examples where the purpose of the economic analysis has been confused with that of the financial analysis. The following table provides a comparison of the major attributes related to economic and financial evaluations.

[104] NFAT Business Case Chapter 9, pages 4-5.
[105] CAC Harper Econalysis, page 15.
[106] La Capra, Technical Appendix 9A, pages 9A-15.

	Economic Evaluations (standard benefit/cost methodology)	Financial Evaluations
Type of Costing	Incremental, only those costs/revenues that would be incurred if the project proceeded	All relevant costs/revenues including reallocated and overhead costs and sunk costs
Operations	Project only or project with considerations of how other operations may be affected	Total financial operations of the corporation
Measurement	Net Present Value benefit to Manitoba Hydro (domestic customers and project partners)	Rate increases & consumers revenue for domestic customers, effect on financial targets
Price Levels	Constant currencies with real escalation, ignoring general inflation (real $)	Nominal currency with real escalation & inflation (current $)
Financing	Specific funding requirements not relevant; reflected in the discounting of cash flows	Project funding, interest payments, debt repayments explicitly included in costs and revenue requirements
Depreciation	Depreciation not directly applicable. Residual Value calculated for project life longer than 35 year study period	Depreciation used. Residual value not needed as project cost calculated annually

10.2.1 Use of 78-Year Total Study Life is Appropriate

As stated in Appendix 9.3 of the NFAT submission, the total study life used in the economic analysis is 78 years. To reflect this total study life, Manitoba Hydro combined two approaches - a 35 year detailed evaluation and a long-life asset evaluation which extends from the end of the 35 year study period to the end of the 67 year service life of hydro-electric generation assets as representing the longest lived assets. The 78 years reflects the in-service dates of new hydro-electric generation will occur in approximately 2025.

The appropriate primary metric in economic analysis that reflects the total study life is NPV. La Capra's Mr. Peaco acknowledged the importance of this metric stating that "-- the net present value over -- over the life of the investment asset clearly is an important metric, and we've -- we -- we would routinely do that as a matter of course anyway."[107] In addition, MPA agreed that the calculation of a 78 year NPV represents both a detailed study period and a residual or terminal value.[108]

Whitfield Russell Associates however argued that a shorter time frame should have been used.[109] In addition, La Capra, while acknowledging the superior total study life analysis, suggested shorter timeframe analysis could have complemented the 78 year NPV analysis.[110] In particular, Mr. Athas says, "We've actually said many times that they [20-year to 50-year NPV's] complement the information of the seventy-eight (78) year NPV"[111] and, "NPV is always an important measure. Most of these other measures. . . you probably wouldn't want to use without having – being aware of what the NPV is."[112] Mr. Bowman on behalf of MIPUG indicated that although a coarse tool, he would have liked to have seen NPVs calculated over a horizon that is shorter than the full forecast scenarios.[113]

While it is certainly true that shorter-term metrics may be helpful and insightful, there is little justification for shorter-term NPV as a metric in economic analysis. Rather, because financial analysis inherently provides short term metrics, it is more appropriate for this purpose.

In order to compare alternatives on an "apples to apples" basis, it is important that the time frame of the economic analysis extend to the end of the useful life of the longest-lived assets under consideration. In this context, these assets are hydroelectric and transmission facilities and the 78-year time frame reflects their useful life. Any analysis with a substantially shorter time frame, without significant terminal value, attributes insufficient value to these assets. As Dr. Borison points out in his report[114], the effect of adopting this approach is to assume that the long-term future is known with certainty and all assets are known to have zero value in that future. This position is inconsistent with the expectation that these assets will have value in the long-term.

As a result, metrics which ignore residual or terminal value are of little value in an economic analysis. La Capra provided a number of such metrics which ignore residual or terminal value, the cumulative present value or CPV metric is one such metric. La Capra describes the

[107] Transcript, Peaco, page 5583, lines 13-17.

[114] Schedule 3 of Rebuttal Evidence of Manitoba Hydro, MH Exhibit #85, pages 9-10.

CPV metric as one that provides "valuable information to decision makers"[115] and that can be "especially useful in reviewing risk, since the risk profile of different development plans can vary greatly over time"[116]. In testimony, Mr. Peaco confirmed that the residual value of the capital stock is not included in the CPV metric used in La Capra's economic analysis.[117] Mr. Peaco also confirmed Dr. Grant's understanding that,

> "... both the breakeven column and the CPV columns are really just saying that the Keeyask/Conawapa based projects are more capital intensive, and so there's large capital outlays initially. So you're not going - - they're going to show up as negative CPV..."[118]

Effectively, the CPV analysis favours investments in resources with shorter lives such as natural gas and wind generation as it attributes insufficient value to the long-lived resources such as hydro. Manitoba Hydro submits that the CPV analysis provided by La Capra in their initial and supplemental Appendices 9A and 9B is not an approach that should be used for decision making.

La Capra states its preference for anything more involved such as development plan comparisons to be done with a revenue requirements analysis.[119] However, it is the financial analysis, not the economic analysis, that encompasses the revenue requirements analysis. In financial analysis, shorter timeframes and the temporal distribution of costs and benefits are appropriately addressed and that is why Manitoba Hydro dealt with these factors in Chapter 11 of the NFAT submission and its Financial Analysis panel of witnesses. The financial analysis provides the decision-maker information on a year by year basis and on a cumulative basis for a range of critical metrics, including rates and financial targets such as debt/equity and interest coverage, all of which are based on the utility's revenue requirement.

10.2.2 Use of NPV as the Primary Metric is Appropriate

Manitoba Hydro chose NPV as the primary metric for its economic analysis. The economic analysis was designed to show the economic impact of each alternative, and NPV is the "gold standard" in such an analysis as Dr. Borison indicated in his report[120] and testimony[121]. A

quote from finance experts Ross, Westerfield and Jaffe[122] included in Dr. Borison's report is instructive:

"While we found that the alternatives [payback period, discounted payback period, accounting rate of return, IRR, and profitability index] have some redeeming qualities, when all is said and done, they are not the NPV rule; for those of us in finance, that makes them decidedly second-rate…"

This position is supported by Dr. Harper in his testimony[123].

> MR. BOB PETERS: As between the internal rate of return and an expected value calculated on an NPV basis, which is the preferred metric?
>
> MR. WILLIAM HARPER: …since I prefer the net present value analysis, …it would be the expected value…that would be the preferred of the two (2)…

Metrics other than NPV may be helpful and insightful in particular contexts, but they must be used with care in a resource planning context. As Dr. Borison described in his testimony[124], if one had to choose between two investments, a $1,000,000 investment that makes $500,000 (a 50% IRR) or a $1 investment that makes $2 (a 200% IRR), IRR would lead to choosing the $2 gain over the $500,000 gain. On the other hand, NPV would make you richer by $499,998.

Mr. Bowman has described the debate over metrics as a "tempest in a teapot."[125] While the debate can certainly be overdone, this example should make it clear that the choice of metric can be very important. For most of us, passing up an opportunity for $499,998 because of the choice of the wrong metric is more than a tempest in a teapot. While IRR and other metrics are useful as supplements, NPV is the most appropriate and best one to use in this context.

Morrison Park Associates points out the problem with IRR and similar metrics in its testimony[126].

> "Traditional methods and metrics, such as the, you know, internal rate of return, or the rate of return on equity, or the rate of return on capital employed, don't appear to fit very well to the analysis that's required of the Preferred Development Plan and its alternatives".[127]

Dr. Borison emphasized the major role that NPV plays in the evaluation of major capital projects when he said,".... virtually all the work I've done with clients who are interested in decision making about major capital investments, pipelines…mines, power plants, have been based on NPV or a similar metric."[128]

10.2.3 Derivation of Interest Rates, Equity and WACC is Appropriate

A discount rate is a powerful instrument that has the ability to make an investment look strong or vulnerable depending on the selection of a few decimal points, and in the case of this NFAT application, all figures are tremendously significant. Given that sensitivity, Manitoba Hydro carefully reviewed its methodologies for developing and applying these rates. Fundamentally, the choice of a discount rate depends on the perspective of an investor and it was in recognition of this that Manitoba Hydro chose to use several rates: from an economic perspective using the Weighted Average Cost of Capital; from a financial perspective of Manitoba rate payers using a time-preference value; and finally, from the broader perspective of society in the multiple-account analysis.

Embedded within the development of a discount rate are assumptions based upon careful research conducted by Manitoba Hydro and expert consultants. These assumptions were scrutinized in detail throughout the past several months by all Interveners and Independent Expert Consultants. Specifically related to discount rates used in the economic and financial analysis are the key assumptions of interest rates, equity rates, and the application of uncertainty against these.

By combining interest, equity, weighting them by corporate policies, adjusting for inflation and for uncertainty, one comes to final values of the ranges of discount rates used in the economic analysis. Manitoba Hydro used 3.37% as a low real discount rate, 5.05% (updated to 5.4% in 2013) as a reference real discount rate, and 6.5% as a high real discount rate.[129] Probability weightings of 15%, 50% and 35%, respectively, were derived based on historic patterns and also to recognize that there is greater scope for interest rates to rise from their

[127] Transcript, MPA, p. 7274, lines 3-8.
[128] Transcript, Borison, page 1686.
[129] CAC/MH I-127.

current levels than for rates to decline.[130] These weightings produce a weighted average value of 5.3%. As demonstrated in PUB/MH I-165a, this is in fact slightly higher than the average historic rate levelized over a twenty year period.

10.2.3.1 Interest Rates

The core of the discount rate used by Manitoba Hydro in the economic analysis is the assumed interest rate. Simply put, the higher the interest rate, the higher the cost of debt, the higher the discount rate, and the less attractive an investment becomes. Manitoba Hydro's interest rate is determined through the industry best practice of obtaining a consensus view of interest rates from a number of credible, well-respected forecasting agencies and banks. Details of all sources and the method for averaging were provided in PUB/MH I-065, along with the forecasts of other key economic indicators like inflation, economic growth and exchange rates. Next, the consensus average, or view of projected long term Canadian bond rates, are adjusted for the Province of Manitoba's borrowing spread over Canada's costs, and finally, the current 1% provincial guarantee fee is added. The response to Information Request CAC/MH I-104 details how the 6.3% interest rate, or cost of debt was calculated, and a very detailed calculation of the 2012 and 2013 real weighted average cost of capital (including interest rates) is provided in the response to PUB/MH I-156a.

Given the sensitivity of investment decisions to the assumption of an interest rate, it was the focus of much attention in this proceeding. Morrison Park Advisors (MPA) argued that Manitoba Hydro biased their analysis: "...there's been a bit of bias in Manitoba Hydro's evidence with respect to recent history, particularly with respect to inflation and interest rates."[131] MPA points to the fact that history has experienced a much broader range of both interest and inflation and supports this by citing the amount of data available from both Statistics Canada and the Bank of Canada. This suggestion overlooks the fact that Manitoba Hydro takes a very long-run perspective of the data from both Statistics Canada and the Bank of Canada, as well as from the Federal Reserve in the United States.[132] As demonstrated in the response to PUB/MH I-165a, Manitoba Hydro used 20-year levelized values of real interest rates. These calculations start with data from 1940, thus starting at a low interest rate point similar to current conditions, capturing several social, political and economic eras, including the peaks and troughs experienced during the 1980's, 1990's and the recession in 2008.

[130] NFAT Appendix 9.3, pages 54-56.
[131] Transcript pages 7271-7272.
[132] PUB/MH I-163a, PUB/MH I-165a, LCA/MH I-207.

The reference nominal long-term debt assumed by Manitoba Hydro for the 2012 planning assumptions used in the NFAT submission was 6.30%, the low nominal long-term debt was 3.65% and the high nominal long-term debt was 8.95% (Appendix 11.2). When adjusting these for inflation they are 4.40%, 2.65%, and 5.95%, respectively, and compared to historical values cited by MPA and filed in PUB/MH I-165a, these real rates are well within the range experienced by a history beginning in 1940, and in fact, is biasing toward higher rates.

In response to information request PUB/MPA I-029b, MPA suggested that nominal Bank of Canada interest rates of 3.00%, 5.00% and 7.00% may be more appropriate to use, and that these would convert to Manitoba Hydro interest rates of 4.3%, 6.6% and 8.9% nominal when the 1% provincial guarantee fee and the Manitoba/Canada spread of 0.3%, 0.6% and 0.9% are added.

Using MPA's suggested nominal rates to determine real discount rates based on a 3% imputed return on equity for a 75/25 debt/equity ratio, and based on inflation set at 1%, 2% and 3% respectively, results in a low real discount rate of 4.02% (compared to Manitoba Hydro's of 3.35%), a reference real discount rate of 5.26% (as compared to Manitoba Hydro's of 5.05% - updated to 5.4%) and a high real discount rate of 6.48% (as compared to Manitoba Hydro's of 6.5%).

MPA does state that their reference and high rates are "...basically consistent with the choices made by Manitoba Hydro", but that but the low rate is higher.[133] Using the same probability weightings of 15%, 50% and 35%, results in a weighted discount rate of 5.50%, which is only slightly higher than the 5.30 used by Hydro. MPA suggested that there was little support for Hydro's low discount rate but when pressed under cross examination admitted that the interest rates at or below this level have occurred on a number of occasions.[134] Similarly, La Capra assigned a zero probability to the low interest rate scenario, despite not conducting any analysis of the assignment of probabilities[135] and on cross-examination agreed that "...there's definitely not a zero probability".[136]

Oddly, Mr. Harper suggested that in order to provide a better comparison between high and low capital cost and export price cases, the discount rate should be held constant and no

[135] Transcript page 6279, line 20.
[136] Transcript pages 6276-6277.

discount rate sensitivities should be undertaken.[137] Manitoba Hydro quite simply does not agree that holding a known uncertainty constant will help uncover uncertainty.

10.2.3.2 Equity

Manitoba Hydro is not an investor-owned company and so equity in the traditional sense does not apply. Manitoba Hydro is not regulated on a rate-of-return basis – rates are set to recover costs and to make contributions to retained earnings. Retained earnings provide an equity buffer that can accommodate normal business risks. As a proxy for an allowed rate of return, Manitoba Hydro estimates the return on equity as 3% over its cost of debt. Allowed rates of return on equity (ROE) for other utilities were used to determine the 3% equity adder that Manitoba Hydro utilizes as this proxy for an allowed rate of return. Regulated returns on equity in the utility industry across North America are regularly examined, and Manitoba Hydro remains satisfied that its policy to add 300 basis points (3%) to the forecasted "all-in debt" remains appropriate. A discussion of this point was provided in the response to PUB/MH II-381b; the calculations can be confirmed in PUB/MH I-156a; and examples of recent returns on equity can be found in MH Exhibit #182, Tab 18.

Mr. Harper took the view that the WACC was 0.15% too low because the spread (4.65%) between Hydro's cost of equity and its 2018 forecast of the Canadian long bond rate was less than the current (5.25%) spread approved for some Canadian utilities.[138] Specific spreads between the Bank of Canada long-term (10+ years) interest rate and the allowed returns in other jurisdictions can help to verify the reasonableness of Hydro's imputed return on equity, but they must be used with a degree of caution. It is common in rate of return hearings to express the allowed equity returns as a fixed spread from the 10 and/or 30 year Bank of Canada rate. Automatic adjustment mechanisms are often implemented to allow for equity returns to vary with interest rates. Since equity returns required by the market do not move in lockstep with interest rates, bounds on interest rate movements or time limits are often attached to these mechanisms. During periods of dramatic interest rate swings, many of these adjustment mechanisms are abandoned. Recently, many of the adjustment mechanisms have included additional factors in attempt to recognize the plasticity of the spread between equity returns and the Bank of Canada rate. Mr. Harper cited BC, Alberta and Ontario decisions as support for a higher Manitoba Hydro discount rate based on their fixed spreads above the Bank of Canada rate.[139] In fact, the approved mechanisms demonstrate that equity returns are not fixed relative to the Bank of Canada rate. The BC mechanism, which expires

[137] CAC Exhibit #30, page 41.
[138] CAC Exhibit #30, page 21.
[139] CAC Exhibit #30, page 21.

in December 2015, has a set floor and movement in the Bank of Canada rate drives only 50% of the change in the return on equity.[140] Equity returns in Alberta are set at a fixed 8.75% with no provision to adjust to changes in the Bank of Canada rate.[141] The equity return approved in Ontario at 9.36% also has an adjustment mechanism that uses only 50% of the change in the Bank of Canada rate and 50% of the change in a utility bond index.[142] No intervener or IEC witness provided evidence as to what spreads over the Bank of Canada rate would be allowed in 2018, the year that Manitoba Hydro uses in the determination of its WACC. The equity returns recently allowed in BC (8.75%), Alberta (8.75%) and Ontario (9.36%) suggest that the imputed nominal equity return of 9.3% (now 9.75%), used to calculate Manitoba Hydro's real WACC is reasonable and is somewhat above the average allowed return.

Morrison Park Advisors criticized Manitoba Hydro's value and application of a fixed equity premium within the calculation of the WACC. In PUB/MPA 1-030(a) MPA suggested a premium should be "…at least 5% above Canada Long Bonds…" as compared to Manitoba Hydro's 4.5% above Canada Long Bonds. MPA however readily acknowledges the inherent challenge faced by Manitoba Hydro with respect to embedding equity within the WACC: "…the complicating factor is you're—we're not looking at the project. We're looking at Manitoba Hydro as a whole. And, you know, it – it operates under a cost-of-service legislation. So the – the question of weighted average cost of capital and what's appropriate is always a challenging one, in – in this case, as it is and most others."[143] This point is similarly reinforced in their report: "…Manitoba Hydro is governed by "cost of service" legislation, which nominally requires Manitoba ratepayers to bear all of Manitoba Hydro's costs, and Manitoba Hydro benefits from a Province of Manitoba guarantee of substantially all of its debt."[144] MPA underscores the critical aspect that Manitoba Hydro does not have investors by the most common definition, but rather invests on behalf of the public: "…there's no investor that's putting equity into a new project. Manitoba Hydro gets its revenue – gets its capital either from retained earnings from ratepayers or from government-guaranteed debt."[145]

Although there has been criticism levied against Manitoba Hydro with respect to the value and application of equity within the weighted average cost of capital calculation, the question regarding what is appropriate has been acknowledged to be challenging and any attempts to

provide alternatives have resulted in values immaterially different. Manitoba Hydro submits that the equity component of its weighted average cost of capital calculation is reasonable.

10.2.3.3 Weighted Average Cost of Capital

Projected debt and equity rates are weighted by Manitoba Hydro's 75/25 debt/equity ratio target, resulting in the weighted average cost of capital (WACC) that is used as the discount rate. The 75/25 weighting is used irrespective of when the target ratio is actually achieved for each alternative. Manitoba Hydro's methodology for deriving the WACC disregards years prior to 2018 so as to determine a stable long-term rate, and in this case, the WACC is based upon the significantly higher interest rates forecasted for 2018 and years following.[146]

It should also be noted that economic and financial analysis by Manitoba Hydro were conducted in inflation-adjusted or 'real' values. This simply means that the effects of inflation are removed to examine what economists phrase a 'real' effect, not subject to inflationary changes in prices. Over the course of the hearings there has been some confusion on this topic. It is important that the reader of the material be mindful of whether the information they are reviewing is in real or nominal values, as these values are not interchangeable. For example, MPA incorporated nominal values in their analysis[147], while Manitoba Hydro used real values. Both nominal and real calculations were provided in numerous information requests and are referenced in detail in PUB/MH I-156a.

10.2.3.4 Uncertainty in the Forecast of Interest Rates

It is important to identify the foundation of uncertainty that influences a decision or an assumption. In the formation of Manitoba Hydro's WACC, the principal uncertainty is derived directly from the core assumption: the forecast of interest rates. Uncertainty within this context is best dealt with through recognition and study of the inherent uncertainty incorporated within the interest rate forecast. Acknowledging this sensitivity, a reasonable and appropriate range of rates that could persist for long periods of time was established.[148] This range was not intended to capture short-term fluctuations in interest rates. Detailed in the response to PUB/MH I-165a are historic Bank of Canada long-term nominal interest rates from 1940 through 2012, and these have varied from a low of 2.33% to a high of 15.22%. Inflation rates have ranged from a low of minus 1.41% to a high of 14.56%. By combining these, one can calculate the resultant real interest rate, which has ranged from a low of minus

[146] NFAT Appendix 11.2, PUB/MH II-455.
[147] Transcript page 7272, lines 1-2.
[148] NFAT Appendix 9.3, page 32.

10.16% to a high of 8.10%. The mathematical treatment used for inflation adjustment is provided in PUB/MH II-503b. As demonstrated in PUB/MH I-156a, when these values are averaged over a twenty year period (equivalent to a compounded 20 year interest rate), values range from a low of minus 0.19% to a high of 5.36%, and an average of 2.94%.

With respect to inflation, in addition to the historical data provided above, it is very important to examine and consider the monetary policies set forth by the Bank of Canada. Ever since it was established in February 1991, the Bank of Canada has targeted inflation of 2% plus or minus 1%, and it was this logic along with historical data that formed the basis of the range of inflation. The current policy was filed in LCA/MH I-207 as well as the historical data from the Consumer Price Index (CPI), a measure of inflation.

10.2.4 Use of 27 Scenarios is Appropriate

As described in Dr. Borison's evidence,[149] Manitoba Hydro initially identified eleven separate uncertainties in six categories. Based on an examination of the timing and magnitude of these uncertainties, Manitoba Hydro chose to incorporate the three factors with the greatest impact explicitly in the probabilistic analysis. Other important uncertainties were captured using sensitivity analysis.

In his evidence, Mr. Harper argued that Manitoba Hydro could and should have incorporated more uncertainties into its probabilistic analysis[150]. There is a disadvantage to including additional uncertainties. It requires time and effort, reducing the amount that can be spent on other important aspects of the analysis and it adds to the complexity of generating, interpreting and communicating results. This would impede the ability of parties to understand the case. Furthermore, as noted in the NFAT submission[151], Manitoba Hydro's examination of the uncertainties indicated that those uncertainties not included in the uncertainty analysis had relatively little impact, meaning that the benefits of including them in the uncertainty analysis would be minimal even if it is technically feasible.

10.2.5 Treatment of Discount Rate Uncertainty is Appropriate

Manitoba Hydro chose to incorporate the discount rate (and associated economic indicators) as one of the uncertainties in the probabilistic analysis. Both Mr. Bowman and Mr. Harper have argued that it is not appropriate to include discount rate as an uncertainty either because

[149] Schedule 3 of Rebuttal Evidence of Manitoba Hydro, MH Exhibit #85, pages 6-7.
[150] Transcript, Harper, pages 8510-8513.
[151] NFAT Business Case, Chapter 10, page 4, Figure 10.1.

1) it makes comparison of alternatives difficult or 2) it makes discount rates and interest rates hard to separate.[152,153] In contrast, as initially explained by Dr. Borison[154] and discussed further in testimony[155], the explicit treatment of discount/interest rate uncertainty in a long-term context, while analytically challenging, is well accepted and even required. A quote from an article by Harvard Professor Weitzman[156] cited in Dr. Borison's report is instructive, both as far as the treatment of discount rate uncertainty is concerned and the link with interest rates:

> While there is uncertainty about almost everything in the distant future, perhaps the most fundamental uncertainty of all concerns the discount rate itself. The question before us is how to discount this distant future in such a way as will induce us to make the best possible investment decisions now, in our present state of uncertainty about the relevant interest rate that will then apply.

10.2.6 Use of the Probability Tree Approach Is Appropriate

There are three major uncertainties in Manitoba Hydro's analysis:

- Energy prices
- Capital costs
- Discount rate (and other Economic Indicators)

In uncertainty analysis, the fundamental goal is to estimate the range of possible outcomes for key metrics if a particular alternative is chosen. Generally, the range is expressed as a probability distribution. This analysis enables stakeholders to compare alternatives rigorously and make more informed decisions. In most business and policy decisions, one relies on an engineering/economic model for estimating outcomes for a particular setting of inputs. The inputs include both the choice of alternative (such as building a dam) and the setting of various parameters that we cannot directly choose (such as natural gas prices). As emphasized in cross examination, there are two fundamental ways of using a model to

[152] Mr. Bowman's Pre-filed Testimony, page B-7.

generate the desired uncertainty analysis output.[157] These are Monte Carlo simulation and probability (or decision) tree analysis.

Manitoba Hydro chose to take a probabilistic scenario or probability tree approach for quantifying these uncertainties, while Dr. Simpson favours a Monte Carlo simulation approach[158].

These two approaches can really just be thought of as alternative sampling methods for uncertainty analysis. Monte Carlo tends to work well with simple spreadsheet-level operational models with lots of similar well-behaved inputs. One can associate known distributions with the inputs, press go, run the simple model thousands of times or more, and generate an accurate and credible outcome distribution quickly. Probability trees tend to work well with more complex investment models with fewer, more diverse inputs. One can evaluate each input in depth, develop customized scenarios, run the complex model hundreds of times or fewer, and generate an accurate and explainable output distribution efficiently.

It is important to point out that probability trees can be extended naturally to the analysis of optionality. One can easily expand the tree with current and future decisions, learning and flexibility. It is extremely difficult (and perhaps impossible) to incorporate optionality well into a Monte Carlo simulation. That is one reason it is more of an operational than a strategic tool.[159] [160]

It is instructive to consider that Dr. Simpson was unable to provide a single example of the use of Monte Carlo simulation in the development or evaluation of a long-term resource plan or a single example of the use of Monte Carlo simulation to evaluate alternatives in Integrated Resource Plans.[161]

Dr. Bowman concurs regarding the benefits of the probability tree or probabilistic scenario approach in this context[162].

> MS. MARLA BOYD: Would you agree that probabilistic scenario analysis often provides more transparency than Monte Carlo simulations?

MR. PATRICK BOWMAN: Yes, absolutely, and...especially in a regulatory forum. If -- it would be different if you were running a university department or something where a bunch of people could gather around a computer monitor and rerun scenarios and -- and discuss them or something of that nature. But if you've got a file -- some evidence and people need to be able to cross-examine you on it, Monte Carlo simulation is a very difficult way to find out if you've -- if you've done everything correctly, to be tested, to -- to have a proper cross-examination and evidence.

10.2.7 Approach Used to Assign Probabilities is Appropriate

Manitoba Hydro agrees that quality data is important in uncertainty analysis, just as it is in other forms of analysis. As Dr. Borison noted in his report, the inputs in the analysis were developed and calibrated carefully using a mix of historical data, model results and expert judgment.

Manitoba Hydro went to considerable lengths to draw upon available data, models and judgments in developing the underlying probability distributions, and in assigning discrete probabilities. This stands in contrast with La Capra who have relied on what appear to be largely arbitrary and casual probability assignments in what Mr. Athas referred to as a "mathematical exercise".[163]

Manitoba Hydro also updated its inputs to the probability analysis as soon as new information became available. Capital costs were refined based on new estimates[164], and the treatment of common factors (those not incremental to a particular alternative) was improved to better reflect the relative risk of individual alternatives[165].

10.2.8 Use of the Utilitarian Approach Is Appropriate

Manitoba Hydro's probabilistic analysis is based on the "utilitarian" approach to measure the impact of uncertainty for each development plan, rather than the "regret" approach. The utilitarian approach is based on "What Is" - the actual incremental impact of each alternative in each scenario. There is a fixed base value, but the choice of this base makes absolutely no difference in the comparison of alternatives. The regret approach is based on "What Could Have Been" - the difference between the actual incremental impact in that scenario and the

[163] Transcript, Athas, page 6031.
[164] Transcript, Bowen, pages 2601-2609.
[165] Transcript, Miles, pages 2517-2522.

impact if another base alternative had been chosen. The choice of this base alternative (not just a base value) is arbitrary, and can make a significant difference in the comparison of alternatives.

The distinction between utilitarian and regret approaches is not simply an academic debate, as the choice between approaches can have real significance. For example, the utilitarian approach provides a stable, useful measure of the risk of each alternative. No matter what base value is chosen, the relative risk of the alternatives remains the same. The regret approach provides no such stable, useful measure. The alternative that is chosen as the base, whatever that might be, appears as "riskless" not because there is no risk but because there is no disappointment when an alternative is compared to itself.

As La Capra acknowledges, in reality, each alternative, including the base, has risk[166]. Yet the approach that La Capra used in its analysis will show as riskless whatever alternative is chosen as the base, whether this is the All Gas plan, the Preferred Development Plan or another plan[167]. This makes use of this approach, except as a very limited supplement, suspect. Despite this, La Capra persists in discussing the outputs of this approach as if it provides an indication of risk. This is evident when Mr. Peaco says[168]:

> You can see how much the range is, so if it's net present value of...a billion dollars, but it's plus or minus $3 billion, that's important to know as opposed to if it's plus...or minus 10%.

However, this approach provides no such indication since the "risk" depends entirely on the arbitrary choice of the baseline alternative. The lack of foundation and the resulting problems with the regret approach are described in more detail in the response to MIPUG/MH II-004a.[169]

Manitoba Hydro addressed the use of the regret approach in its Rebuttal Evidence[170], where it referred to the regret approach as fundamentally descriptive (i.e., what individuals do naturally) rather than prescriptive (i.e., what organizations should do rationally). In this context the regret approach may be helpful to particular stakeholders but only as a supplement to the better-founded and better-accepted utilitarian approach.

As Dr. Borison indicated in his testimony, any approach that is based on a regret table is fundamentally a regret approach.[171] It is basing comparisons and recommendations not on "What Is" but on "What Could Have Been". Further, as Dr. Borison makes clear, there is no justification for arguing that a rational organization should make important decisions this way. Any S-curves generated with this approach are fundamentally regret-based and have little if any decision-making value[172]. Mr. Bowman supports Dr. Borison's position when he says, "I -- I think Dr. Borison was correct in -- in not advocating that... but La Capra's graphs are the same graphs you would draw if you were advocating that type of approach [a regret approach]."[173]

Manitoba Hydro chose to use the more appropriate utilitarian approach in its probabilistic analysis. This was supported by Dr. Borison in his direct testimony[174]:

> ...virtually all the theory about how to do decision making on uncertainty says you should compare things to a fixed base....you should look at your current wealth and say...If I did this, I'd be that much wealthier; if I did that, I'd be that much wealthier....That is the fundamental theoretical basis of utility theory.... The approach that is...not well regarded as a guideline...is to compare where you are to what would have happened in that particular scenario....I refer to that as the regret approach....the fundamental difference is having a bunch of zeros for any alternative in all scenarios...saying I'm going to compare things to what might have happened in that scenario...whatever you want to call it, I think it is, frankly, unconventional and misleading, comparatively speaking...

There are numerous examples of the use of the utilitarian approach in resource planning. There are no such examples of the use of the regret approach.[175]

10.2.9 Use of 10th Percentile Risk Metric is Appropriate

One key output of economic uncertainty analysis is typically the expected value, obtained by weighting each outcome with its probability. However, it is useful to go beyond expected value to look at the variability around this "central tendency." As explained in two

[171] Transcript, Borison, pages 2458-2460.

[175] MIPUG/MH II-004a.

interrogatories[176], Manitoba Hydro agrees that risk should be considered, and that risk/return tradeoffs and "efficient frontier" graphics are insightful. However, it is critically important that the right risk measures be used.

Dr. Simpson argues that risk should be measured using interdecile ranges or similar metrics such as standard deviation that incorporate both downside and upside variability.[177] These metrics are commonly used in academic and financial contexts where distributions are assumed to be symmetric (as with the normal distribution). But they can misinform where the distributions are not symmetric, which is often the case in non-academic and non-financial applications such as utility resource planning.

Manitoba Hydro chose to measure risk based on the 10th percentile value – a bad or worst case – because this better captures the essence of risk in the utility planning context. As explained in detail in CAC/MH I-0184a[178] and Dr. Borison's testimony[179], the 10th percentile risk measure is better than traditional financial measures such as interdecile range and standard deviation. It provides a much better sense of the true risk/return tradeoff.

10.3 Economic Analysis Results

In the NFAT Business Case Chapters 9, 10 and 12, Manitoba Hydro provided economic analysis and economic uncertainty analysis for up to 15 development plans. Through the course of the NFAT process, Manitoba Hydro has provided supplementary analyses[180] with respect to additional levels of DSM and updated assumptions such as updated capital cost estimates for Keeyask and Conawapa Generating Stations.

In the NFAT Business Case, Manitoba Hydro provides the impact of potential transfers to the Province which includes water rentals, capital tax and the provincial guarantee fee[181]. Appendix 9.3 Section 1.4 of the NFAT submission discusses the return on equity (ROE) included in the real weighted average cost of capital (real WACC). The real WACC is used in the economic analysis as a discount rate. In its supplementary analysis filed as MH Exhibit #171, Manitoba Hydro presents the NPV at the real WACC which has in it an embedded ROE. Manitoba Hydro also presents the increase in NPV by excluding the embedded

ROE[182]. The total NPV including ROE represents the return, in excess of debt costs, which is available to Manitoba Hydro. It should be noted that a portion of the embedded ROE is required to maintain Manitoba Hydro's debt equity ratio of 75:25. The cash transfers to the Province are shown in addition to the NPV excluding ROE in order to provide an indication of the total direct economic benefit to Manitoba.

Embedded Return on Equity in Discount Rate

Manitoba Hydro's WACC includes an imputed return on equity of 3% over the projected cost of long-term debt. Equity is assumed to constitute 25% of Manitoba Hydro's capital structure, consistent with its current financial targets. Unlike many other jurisdictions, the requirement for an equity return in Manitoba Hydro's WACC is not to produce a required return to a shareholder, but to be the vehicle by which Manitoba Hydro can achieve its financial objectives and to provide tangible ratepayer benefits. While generally seen as a benefit to Manitoba Hydro, retained earnings are really another form of ratepayer benefit; they provide rate stability in adverse situations and preserve Manitoba Hydro's self-sustaining financial status to ensure its continued access to low cost financing through the Province. MPA also supported this view in their evidence, "By definition, because Manitoba Hydro is structured as a cost-of- service company, all of its retained earnings are invested in capital, which are -- are used for the benefit of providing service to ratepayers."[183]

As there was some confusion regarding embedded return on equity, the concept is explained as follows: a project that has a zero net present value using a debt-only discount rate (no equity premium) will, over the long term, cover all of its financing costs but nothing more. Any return above the debt-only discount rate constitutes a net positive cash flow that can be used to provide benefits. As has been stated by Manitoba Hydro in Ms. Flynn's testimony[184], a portion of this return is necessary to make contributions to retained earnings otherwise known as net income. The relative share of the 3% equity premium necessary to contribute to retained earnings will be similar in all of the alternative plans.

The portion of the 3% equity premium not required to maintain financial reserves is available for two purposes: to act as a buffer against business risk, and to reduce the rates that would otherwise be required to be recovered from customers.[185] This embedded equity return is not

[182] MH Exhibit #171.

readily identifiable in the corporate financial statements, but is a real benefit that is a direct result of projects that earn returns in excess of their debt-only cost of capital.

Transfers to the Province

The construction and operation of the development plans include a range of financial transfers to the Province of Manitoba, in the form of capital taxes, water rental fees, and loan guarantee fees. With respect to the capital tax and the water rental fee, explained by Mr. Rainkie (Tr. p. 2977), and quantified in Exhibit #171, there has been no disagreement that these represent cash transfers which benefit the Province of Manitoba. There has been some discussion regarding the classification of the provincial guarantee fee, and whether or not it is a benefit to the Province. This subject merits attention because the potential magnitude of incremental benefit could be up to and beyond $1.0 Billion dollars as seen in Exhibit #171. Manitoba Hydro takes the position that a portion of the provincial guarantee fee should be included in the determination of total benefits to the province associated with the development plans. Excluding the debt guarantee fee would be justified if the province incurred direct costs or assumed risk proportionate to the fee. While the entire 1% fee represents value for service provided to Manitoba Hydro, the actual cost to the province is unclear (Tr. p. 3971-3972).

Dr. Marvin Shaffer, retained by Manitoba Hydro to undertake the Multiple Account Benefit Cost Analysis took a conservative approach when considering the net benefit of the provincial guarantee fee to the Province, "…in some respect […] the debt guarantee that the government is providing, and there are – there are costs or risks associated with that."(Tr. 3656) Consequently, he decided to not include provincial guarantee fee as a net beneficial transfer to the Province; however as demonstrated below, the issue is clearly not black-or-white.

Mr. Colaiacovo in testimony was asked by the Chairman whether the fee was too high or low, and in response explained that they did not make that determination. However, in this explanation MPA suggested that the evaluation would include an analysis of the "likelihood and magnitude of a call on that guarantee," and while they did not provide that analysis, he did explain that in other jurisdictions the fee is "..twenty (20) basis points, or thirty (30) basis points, or fifty (50) basis points." (Tr. 7298) This testimony underscores the uncertainty as to whether and by how much the fee is offset by cost and risk.

One intervener took the position that the provincial guarantee fee should be classified as a benefit - Mr. Bowman testified: "And—and I definitely include debt guarantee fees in that mix. I think of somebody is going to sit down and – and sort out a solution here, debt guarantee fees would – would need to be on the table for this" (Tr. 10277-10278). Mr. Bowman takes the position that while the provincial guarantee fee does reflect an offset of a cost, there should be some recognition that there is a net benefit.

10.3.1 Economic Conclusions Based on Updated Assumptions

Manitoba Hydro's supplementary economic analysis provided in MH Exhibit #171 reflects higher levels of DSM, potential for increased pipeline load, updated capital costs for the Keeyask and Conawapa Generating Stations, and 2013 planning assumptions. Since the filing of the NFAT submission in August 2013, it has become known that WPS will not invest in the 750 MW interconnection and that development plans with a 250 MW interconnection are not viable possibilities, and are now considered hypothetical.

In MH Exhibit #104-2, and in MH Exhibit #104-8 a portion of which is reproduced below, Manitoba Hydro provided updates to the economic uncertainty analysis results. These updates reflected the updated capital costs for Keeyask and Conawapa Generating Stations and the associated probability weightings for capital costs, removed the WPS investment in the 750 MW interconnection, and updated the treatment of common factors. The uncertainty analysis was not updated for higher levels of DSM.

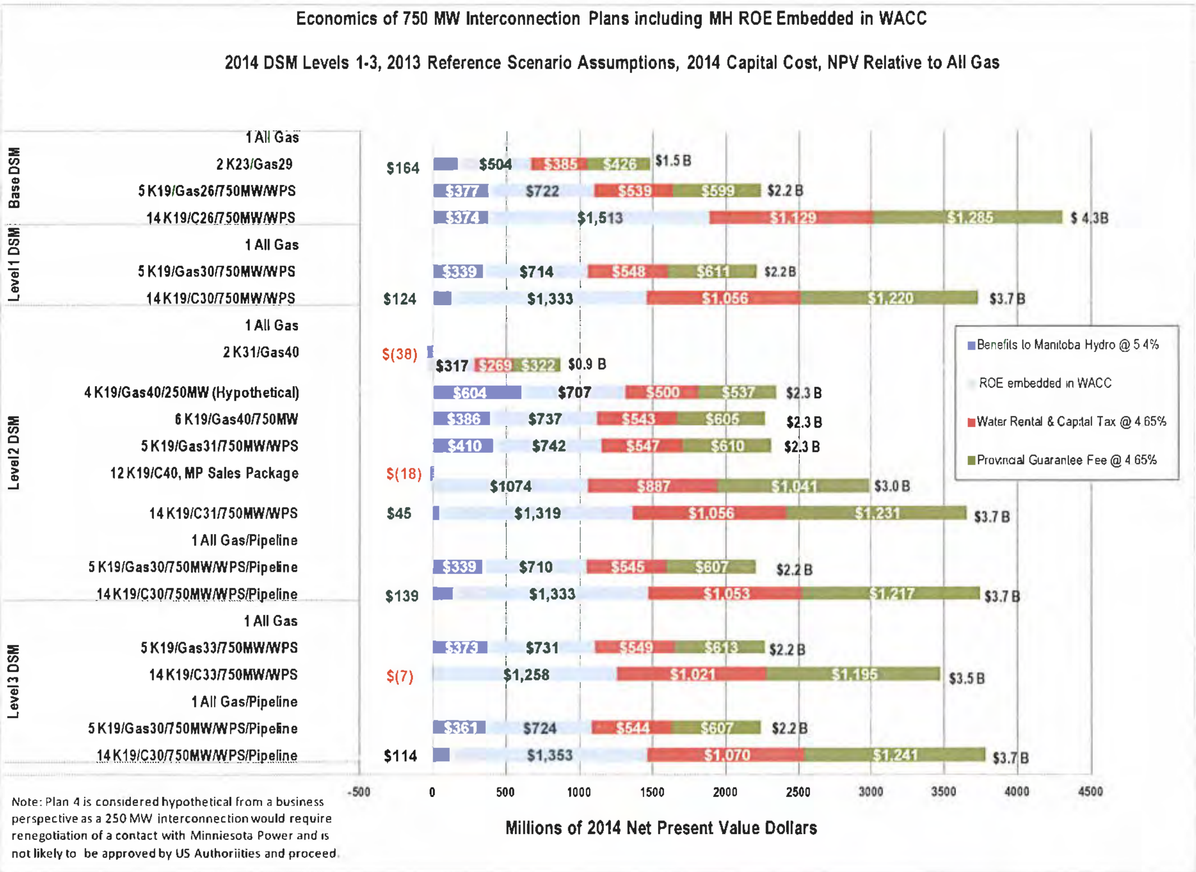
Ref-Ref-Ref NPV	0	489	917	403	662	536	484	614

In the updated uncertainty analysis, the updated treatment of common factors had no effect on the expected value calculation. The updates for capital costs and interconnection investment reduced the expected value for all plans with Keeyask and/or Conawapa Generating Stations.

From an uncertainty perspective, Plan 14 continues to have the highest upside potential but also has the highest downside risk. When considering expected value and the NPV at Ref-Ref-Ref, the focus shifts from Plan 14 to Plans 5 and 6 (Plan 5 – K19/Gas25/750MW (WPS Sale & no WPS Inv); Plan 6 – K19/Gas31/750MW).

MH Exhibit #95, Slide 129 confirms that Level 2 DSM is the most economic of the additional three levels of DSM shown. As a result, Manitoba Hydro focused additional analysis on plans with Level 2 DSM. The majority of the results from the economic analysis are summarized in MH Exhibits #171 and #104. MH Exhibit #171 is reproduced below.



With reference to MH Exhibit #171, at the real discount rate of 5.4%, which includes an embedded ROE, and at Level 2 DSM, the NPVs for Plans 5 and 6 ($410 million and $386 million, respectively) which include the Keeyask Generating Station and a 750 MW interconnection followed by natural gas-fired generation, are higher than the incremental NPV for the Preferred Plan ($45 million) and are higher than all other Plans evaluated under DSM Level 2. Plan 4 (K19/250MW) economics are not discussed because it is hypothetical, as noted in the Exhibit.

From the perspective where the NPV excludes the embedded ROE, the incremental NPV of $1.364 billion for the Preferred Plan is at least $200 million greater than the NPV of the other plans evaluated. The NPVs of Plans 5 and 6 are approximately $1.1 billion higher than the All Gas Plan, and are approximately $0.8 billion higher than the Keeyask/Gas Plan.

When considering cash transfers to the Province, the Preferred Plan with both Keeyask and Conawapa Generating Stations results in a total NPV of $1.4 billion higher compared to Plans 5 and 6. The NPVs of Plans 5 and 6 are approximately $2.3 billion higher than All Gas and $1.4 billion higher than the Keeyask/Gas Plan.

The incremental NPVs support the development of Keeyask Generating Station and a 750 MW interconnection as represented in Plans 5 and 6. The incremental NPV with respect to Plan 14, from the perspective where the NPV excludes the embedded ROE, supports protection of Conawapa Generating Station as an option. However, consideration must be given to the tradeoffs between Plans 5 and 6 and Plan 14. Further analysis of other perspectives (financial, multiple accounts, and optionality) which are discussed in Sections 13, 19 and 21 of Manitoba Hydro's Final Argument are important to the overall conclusions and recommendations provided in Section 22.

10.3.1.1 Keeyask and Conawapa High Capital Cost Stress Test

In MH Exhibit #170, stress test results are provided for Keeyask and Conawapa Generating Station 2014 updated high capital costs. The stress test evaluated the risk associated with capital cost increases that would be uniquely associated with the Keeyask and Conawapa generation stations and considered no concurrent offsetting increases in the capital costs of natural gas generation or in energy prices.

The high capital cost stress test assuming no additional pipeline load for Plans 5 and 6 results in a NPV cost relative to the All Gas Plan of $-168 million and $-192 million, respectively, at the 5.4% real WACC. Including Manitoba Hydro's embedded return on equity would provide an NPV amount of over $500 million that would be available to Manitoba Hydro, relative to the All Gas Plan. In addition, incremental transfers to the Province are approximately $1.3 billion in NPV for Plans 5 and 6. From the perspective where the NPV excludes the embedded ROE, Plans 5 and 6 can withstand increases in capital costs consistent with the updated high capital cost estimate for Keeyask Generating Station resulting in Manitoba Hydro having available to it in the order of $500 million incremental NPV over the All Gas plan.

The high capital cost stress test assuming no additional pipeline load for Plan 14 also incorporates updated high capital cost estimates for both the Keeyask and Conawapa Generating Stations. At the real WACC of 5.4%, the NPV is over $1.2 billion less than the NPV for the All Gas plan. The perspective where the NPV excludes the embedded ROE would result in approximately breaking even with the All Gas plan. Incremental transfers to the Province under this stress test are approximately $2.6 billion.

Experience from the Keeyask Project will inform Manitoba Hydro's cost estimates for Conawapa and as such Manitoba Hydro would not proceed to commit to Conawapa in the face of high capital costs unless there were offsetting factors such as sufficiently higher export revenues. The scenario presented does not take into account such offsetting factors and as such the case presented with both Keeyask and Conawapa experiencing high capital costs would not be considered a feasible or realistic scenario.

10.3.1.2 Manitoba Load - Hypothetical Flat Load Growth Analysis

In MH Exhibit #156 and MH CSI Exhibit #35 an analysis is undertaken of the hypothetical circumstance where Manitoba load growth would remain flat beyond 2022/23.

The analysis of this circumstance used the economic output from existing reference cases including the following assumptions:

- The no new generation case was based on the All Gas plan up to and including 2022/23, with existing export commitments beyond 2022/23 based on future contract terms and conditions.
- The Keeyask & 750MW interconnection case was based on Plan 5 K19/Gas25/750MW (MP & WPS Sales and no WPS investment) up to and including 2022/23, with existing export commitments beyond 2022/23 based on future contract terms and conditions.
- No domestic load growth (flat load) beyond 2022/23.
- From 2023/24 to 2048/49 all energy volumes were held constant.
- Beyond 2048/49, the long-life asset evaluation methodology was applied.

As shown in the following table, if there is no load growth assumed beyond 2022/23 and surplus energy is valued using the 2013 long-term dependable export price forecast, building Keeyask and a new interconnection results in an incremental net present value of $402M (at real WACC of 5.4%) relative to building no new generation. If surplus dependable energy is valued at prices similar to the recently negotiated export contracts, the benefit would be higher than shown in the table below. [redacted]

	Present Valued at a 5.4% Real WACC				
	Capital Cost PV Millions 2014$	Revenue (LTD) PV millions 2014$	Rev-Cost (LTD) NPV millions 2014$	[redacted]	[redacted]
No new Generation	0	3160	3160	[redacted]	[redacted]
Keeyask & 750MW	4605	8167	3563	[redacted]	[redacted]
Incremental NPV			402		[redacted]

The following table shows the same evaluation with the impact of the embedded return on equity removed resulting in a real discount rate of 4.65%. As shown in the table below there is an incremental net present value of $1190M (at 4.65%) relative to building no new generation. [redacted]

The table also shows the NPV benefit of transfers to the province (water rentals, capital tax, and provincial guarantee fee) which when included in the analysis increase the NPV of benefits from $1190M (at 4.65%) to $2422M if surplus energy is valued at the long-term dependable export price forecast. [redacted]

	Present Valued at Real Discount Rate of 4.65% Return on Equity of 3% removed				
	Capital Cost PV Millions 2014$	Revenue (LTD) PV millions 2014$	Rev-Cost (LTD) NPV millions 2014$	[redacted]	[redacted]
No new Generation	0	3675	3675	[redacted]	[redacted]
Keeyask& 750MW	4816	9681	4865	[redacted]	[redacted]
Incremental NPV			1190		[redacted]
Water Rental and Capital Tax NPV			569		[redacted]
Provincial Guarantee Fee NPV			663		[redacted]
Incremental NPV with provincial transfers			2422		[redacted]

From the perspective of hypothetical flat load growth in Manitoba, the analysis shows that there is considerable value in building Keeyask and a new interconnection even under that extreme circumstance.

The question was raised by Ms. Kapitany as to how the MISO market might be affected in the future with respect to lower load growth and how successful Manitoba Hydro might be at selling power to those markets in the future. While Mr. Dunsky recognized there would continue to be a requirement for supply due to retirement of coal plants, he referenced grid parity and DSM programs suggesting that load growth would be flat in MISO in the future.[186] As discussed in Section 9.1.3 (on MISO load growth effect on prices), although load growth assumptions are an important input required to estimate the long-term electricity price for the MISO region, the impact of load growth in determining prices in relative terms is less important than key drivers such as fossil fuel prices, carbon pricing and expected changes to the generation fleet.

As noted by Dr. Murphy in his testimony, supply side pressures in the medium term (which include emerging GHG regulations for coal and expiration of nuclear licenses in 2030s)

[186] Transcript pages 8100-8104.

effectively require new generation supply in MISO to meet load obligations, even under the assumption of very low or flat load growth.[187]

In addition, the evidence from the Brattle Group suggests that because of the characteristics of MISO's supply curve, changes in load growth assumptions are not a primary driver of power prices.[188] In Section 9.1.3 of this Final Argument, it is shown that even under a 1%/year load growth estimate, coal retirements would still represent about two-thirds of the supply shortfall between now and 2020.

As the impact of load growth in determining prices in MISO is, in relative terms, less important than key drivers such as fossil fuel prices, carbon pricing and expected changes to the generation fleet, Manitoba Hydro is confident that it will continue to be successful at selling power to the MISO market in the future and there will continue to be a demand for Manitoba Hydro's predominantly hydro-based product.

10.3.1.3 Keeyask as Next Resource to Meet Manitoba Load

In Section 4 of MH Exhibit #85-2, Manitoba Hydro provided additional economic analysis related to Pathway 1, (Gas 2023 only for domestic load, later gas generation or hydro) and Pathway 2 (Keeyask 2023 only for domestic load, later gas generation or Conawapa). The analysis built on the 2012 and 2013 planning assumptions used in the NFAT submission with the most recent capital cost estimates for Keeyask but does not include higher levels of DSM. The analysis included incremental NPV comparisons related to the timing of Keeyask Generating Station relative to the All Gas plan and resulted in a positive NPV associated with development plans that include Keeyask as a resource option. Overall, these economic evaluation results demonstrate that there remains a net benefit to pursuing Keeyask Generating Station as the next resource for Manitoba load. Based on the analysis in MH Exhibit #85-2 there is value in advancing Keeyask from 2028.

MH Exhibit #171 provides a comparison of Plan 2 (K31/Gas, DSM Level 2) to All Gas (DSM Level 2) and shows the economics to be marginal between the two plans. Based on the information contained in MH Exhibit #85-2, it can be inferred that advancing Keeyask would improve the economics of Plan 2 relative to the All Gas Plan.

[187] Transcript page 1405, lines 12-20.
[188] NFAT Appendix 5.3, page 66.

When considering the NPV excluding the embedded ROE, the incremental NPV for Plan 2 is greater than that of the All Gas plan by $317 million. These results are supportive of Keeyask as the next resource.

10.3.2 La Capra Economic Analysis to be Considered with Caution

10.3.2.1 La Capra's CPV Analysis

In Section 8.2.1, Manitoba Hydro explains that in order to compare development plans on an "apples to apples" basis, it is important that the time frame of the economic analysis extend to the end of the useful life of the longest-lived assets under consideration. In the context of the NFAT, these assets are hydroelectric and transmission facilities and the 78-year time frame reflects their useful life. Any analysis with a substantially shorter time frame, without significant terminal value, attributes insufficient value to these assets.

La Capra calculates the cumulative present value (CPV) of a development plan, which reflects the present value of all costs and benefits that have occurred to a particular point in time. Therefore, a CPV calculation does not include residual value. La Capra agrees that CPV considers only the present value of costs and revenues up to a particular point in time and, by definition, ignores all cashflows whether positive or negative that occur beyond that point in time.[189]

Effectively, the CPV analysis favours investments in resources with shorter lives such as natural gas and wind generation as it gives insufficient value to the long-lived resources such as hydro. However, CPV analysis can be useful in certain limited contexts. For example, La Capra confirmed that CPV could instruct a decision if a potential disruptive technology was of concern at some point in the future.[190] Manitoba Hydro submits that the CPV analysis provided by La Capra in their initial and supplemental Appendices 9A and 9B is an approach that can provide insights but is not an approach that should be used for decision making.

10.3.2.2 LCA No New Generation Plan (Hypothetical) of Little Value

At the request of La Capra, Manitoba Hydro provided SPLASH output and other supporting economic cashflow information which allowed La Capra to prepare an analysis of the LCA No New Generation plan. The plan consisted of increased DSM, as well as fuel switching,

[189] Transcript page 6267.
[190] Transcript pages 6331-6332.

extended diversity agreements, a 750 MW interconnection to the US, and planning criteria for imports increased from 10% to 20% with respect to dependable energy.[191]

Manitoba Hydro considers this plan to be hypothetical as developing an interconnection primarily for import to Manitoba without a counterparty, without identifying whether the region has energy to export, and without identifying any benefit to the region from such an interconnection is unrealistic. While proposed by La Capra, they too acknowledge in their direct evidence[192] that the LCA No New Generation plan is hypothetical. In addition Mr. Peaco was unable to confirm the feasibility of an interconnection primarily for import from Minnesota when he stated "I don't have any basis to know whether it is or isn't feasible."[193]

Mr. Peaco also said that "while it is a hypothetical plan, the results do point to the potential for added elements. DSM, import -- import limit cap -- capabilities are all elements of -- of a plan that -- that may be some -- may be of some promise, either by themselves or in some combination."[194]

Manitoba Hydro sees little value in the hypothetical LCA No New Generation plan as Manitoba Hydro has incorporated the elements of DSM and an interconnection into its development plans and analysis. For example, the 750 MW interconnection (both export and import) evaluated in Manitoba Hydro's development plans recognized the need for a counterparty when developing an interconnection.[195] In MH Exhibits 171 and 104, Manitoba Hydro provides analysis of DSM at various levels. At best, the hypothetical plan confirms that key elements that Manitoba Hydro has already included in its plans are in fact beneficial.

In LCA Exhibit #45, Slides 32 and 71, La Capra calculates an incremental NPV of $1.421 billion for the LCA No New Generation Plan and compares it to the incremental NPV of Manitoba Hydro's Preferred Development Plan of $1.696 billion, a decrease of $275 million. La Capra mainly attributes the $1.421 billion incremental NPV of the LCA No New Generation plan over the All Gas Plan to relaxing the planning criteria related to imports.[196] Mr. Peaco states, ". . . this case was an -- was an opportunity for us to test, you know, does it make any difference if we relax that. And -- and so -- so you see the combined effect of both

[191] La Capra Supplemental Expert Analysis Report, page LCA-5.

[195] NFAT Business Case, Chapter 8.
[196] Transcript pages 5728-5734.

of those things [relaxing the import planning criteria and the 750 MW interconnection] in that case."[197]

In MH Exhibit #104-14, Manitoba Hydro demonstrates that, on a comparable basis, when including the same La Capra load reduction into Manitoba Hydro's analysis the incremental NPV of the Preferred Development Plan increases to $2.607 billion from $1.696 billion, an additional $0.911 billion in incremental NPV as a result of assuming the same load reduction as assumed in the LCA No New Generation plan. This clearly shows that the incremental value associated with the LCA No New Generation plan was primarily due to the assumed La Capra load reduction not the increased level of imports associated with relaxing the import planning criteria. La Capra's analysis was not sufficiently complete to arrive at conclusions with respect to Generation Planning Criteria with respect to the limitation of imports. In this regard, their conclusions are seriously flawed and have led to undue concern with the Generation Planning Criteria with respect to the limitation of imports.

In addition, the comparison of the incremental NPV of the hypothetical LCA No New Generation plan and the Preferred Plan made by La Capra in LCA Exhibit #45, Slides 32 and 71 is not an "apples to apples" comparison as they do not incorporate the same load reduction. The more comparable analysis is provided by Manitoba Hydro in MH Exhibit #104-14, where the NPV of the Preferred Development Plan is shown to increase to $2.607 billion when incorporating the same load reduction as assumed in the La Capra plan. The incremental NPVs of the two plans can then be fairly compared. The resulting comparison shows that the incremental NPV of the Preferred Development Plan with the incorporated load reduction is approximately $1.2 billion higher than that of the hypothetical LCA No New Generation plan.

As discussed in Section 5.3 of this Final Argument, Manitoba Hydro has justified its Generation Planning Criteria with respect to the limitation of imports. All of Manitoba Hydro's analyses respect the Planning Criteria and the importance of maintaining a reliable and dependable supply of power. LCA's No New Generation plan ignores the Planning Criteria without any analysis or regard to the potential impact on system reliability.

In conclusion, as Manitoba Hydro has captured the value of the 750 MW interconnection (import and export) and higher levels of DSM there is little to be learned from the analysis provided by La Capra with respect to the individual or combined elements in the hypothetical LCA No New Generation plan.

10.3.2.3 La Capra Wind/Gas Analysis Provides Skewed Economic Results

In Technical Appendix 3A, La Capra provides an analysis of Manitoba Hydro's Wind/Gas plan (Plan 3) by reducing cost assumptions associated with Plan 3.

In their analysis, La Capra adjusted wind assumptions related to capital cost, capacity factor, asset life and technological improvement.[198] Each one of these assumptions was adjusted specifically to improve the relative economics of the Wind/Gas plan. When taken together, the degree to which these adjustments were made are representative of a stress test which pushes the limits of potential realization for these assumptions (capital cost, capacity factor, asset life and technological improvement).

As discussed in Section 6.4.2, Manitoba Hydro maintains that using a constant capital cost, with no real escalation, and a constant capacity factor for future wind projects are appropriate assumptions for the economic comparison of development plans with wind resource options in the NFAT submission. As explained in Section 6.4.2 using a constant capacity factor and capital cost recognizes improvement as it is typical for capital costs to escalate and for capacity factors to deteriorate when considering wind generation development in the future. Manitoba Hydro maintains that La Capra's capital cost for wind is at the low end of the range and, further, application of technological improvements to this low starting point is not representative of the future capital cost of wind in Manitoba. Manitoba Hydro's position is supported by GACs expert, Power Advisory[199], where they stated "To assume both declining capital costs and increasing capacity factors runs the risk of double counting".

As provided by La Capra[200], the effect on NPV of changes in assumptions made by La Capra to the Wind/Gas plan is $1,234M ($576M + $157M + $234M +$267M). In addition, as shown in LCA Exhibit #45 - Slide 70, even under this stress test, the La Capra Wind/Gas stress test yields the lowest 78 year NPV of the seven plans referenced. Mr. Peaco confirmed that even with the relatively optimistic scenario in the economic analysis the Wind/Gas scenario is still less economic than the Preferred Development Plan.[201]

The magnitude of the changes in the wind assumptions made by La Capra can only be described as extremely optimistic given the inherent uncertainty in the future costs of wind

[198] LCA Technical Appendix 3A, page 3A-28.

development and, therefore, La Capra's Wind/Gas analysis only has value as a stress test. For the purposes of long-term planning, it would be imprudent for resource planners to present such a stress test in a reference scenario comparison.[202] As a result, caution should be exercised when using the economic results related to the La Capra Wind/Gas analysis.

10.4 Risks of Proceeding with Hydro Generation as Next Resources

The risk analysis and the development of risk mitigation strategies are integral to the planning, design and implementation of new resources. This section will discuss the main risks and risk mitigation associated with hydro generation as the next resources.

10.4.1 Risks Associated with Keeyask and the 750 MW Interconnection

It is recognized that there are scenarios with downside risks in which Keeyask and the 750 MW interconnection would not have economic benefits to Manitoba Hydro, although most of the other benefits would still occur. Manitoba Hydro believes that these risks can be mitigated, as described below:

1. *Capital costs increase higher than expected*: Economic and Financial Evaluations, presented in Final Argument Sections 8 and 11, respectively, demonstrate this risk is manageable. Also, if Keeyask capital costs are higher than currently estimated, they likely would also be higher in the competing plans with Keeyask and no interconnection.

2. *Interest rates higher than reference scenario*: This risk was assessed in the economic and financial evaluations and would be manageable.

3. *Electricity export prices lower than reference scenario*: This risk was assessed in the economic and financial evaluations and would be manageable. This risk is mitigated by having long-term export contracts which reduce the exposure to market variations.

4. *750 MW Interconnection not approved by US and Canadian regulatory authorities*: The plans would revert to Plan 2, Keeyask followed by Gas. The benefits would be reduced but the impacts are manageable.

[202] LCA Exhibit# 45, Slide 70.

5. *Lake Sturgeon being listed under Species at Risk Act (SARA)*: If sturgeon are listed as endangered or threatened on the Lower Nelson River, there would be challenges in obtaining SARA operating permits in a timely manner. There could be cost impacts and a risk of delay in commissioning, but these are considered unlikely.

10.4.2 Risks Associated with Conawapa (Following Keeyask and the 750 MW Interconnection)

It is also recognized that there are scenarios with downside risks in which Conawapa would not have economic benefits to Manitoba Hydro, although most of the other benefits would still occur. Manitoba Hydro believes that these risks can be mitigated as follows:

1. *Capital costs increase higher than reference*: This risk can be mitigated by the optionality associated with Conawapa. Information directly pertinent to Conawapa will be obtained during Keeyask construction and if this information indicates that Conawapa costs are likely to increase, Manitoba Hydro would account for that in the business case and halt Conawapa protection and construction if warranted.

2. *Interest rates higher than reference scenario*: This risk would be taken into account in the ongoing monitoring and business case decisions.

3. *Electricity export prices lower than reference scenario*: This risk would be taken into account in the ongoing monitoring and business case decisions.

4. *Inability to successfully negotiate additional long-term contracts which would utilize Conawapa output*: Manitoba Hydro is actively progressing in negotiations with GRE, SaskPower and others. As discussed elsewhere, progress of the negotiations will be closely monitored and will influence decisions on Conawapa activities. The outcome of these negotiations will likely be known well before any Conawapa construction decision is contemplated.

5. *750 MW Interconnection not approved by Canadian and US regulatory authorities*: While Manitoba Hydro believes the interconnection most likely will be approved, the current schedule has the line approved in 2017, prior to a Conawapa construction decision. Should the approval not be forthcoming, the Conawapa activities would be delayed or cancelled.

6. *Lake Sturgeon being listed under SARA*: If sturgeon on the Nelson River are listed as endangered or threatened, there could be challenges in obtaining SARA permits related to Critical Habitat destruction and operations. While Manitoba Hydro expects these challenges will be manageable, the listing decision is expected prior to the Conawapa construction decision and would be taken into account.

10.5 Other Factors That Improve the Economic and Financial Analysis

The economic and financial evaluations utilize the most current information available when the evaluations are performed. Uncertainties are dealt with in the probabilistic scenario analysis, sensitivities and stress tests. However, when undertaking the reference scenario evaluations the input factors and assumptions do not account for certain factors which would affect the evaluations significantly but are not included because there is insufficient specific information to include them at the time or because they became known after the evaluations had been started. Relative to the original August 2013 submission, certain important factors have been included in the 2014 updates such as project capital costs, WPS contract terms and conditions and DSM program updates. As provided in Section 14.5 of the Submission and updated by Mr. Wojczynski during oral testimony[203], there are other factors common to the economic and financial evaluations which have not been able to be included in the updates which are judged to be significant.

10.5.1 Additional Long-term Export Contracts

The economic and financial evaluations do not include a number of known potential export contract opportunities for which the specifics are not sufficiently known to include in the evaluations at this time. As Ms. Flynn testified, inclusion of these export opportunities would increase the economic and financial net benefits and decrease risk, especially of the new interconnection and Conawapa. These export contract opportunities include Great River Energy 600 MW, SaskPower 500 MW, NSP 500MW extension beyond 2025, NSP Diversity beyond 2025 and others which are under discussion but cannot be publicly discussed at this time at the request of the counterparty.

[203] Transcript pages 3682-3683.

10.5.2 Interconnection to Wisconsin Increases Market Access and Overall Export Market Price for Manitoba Hydro

While the evaluations assume that the amount that could be exported or imported would increase with the addition of the new interconnection, they also assumed that the export market price structures with the interconnection addition would remain similar to the price structures without the new interconnection. Mr. Cormie testified that in actuality, the likelihood is that the export prices would increase with the addition of the interconnection.[204] The prices would be increased because there would be a significant number of new counterparties for Manitoba Hydro to contract with and compete with existing counterparties for long-term firm and opportunity term sales. The amount of increases cannot be readily be estimated but would be noticeable and thus increase the benefits associated with adding the interconnection and new hydro.

10.5.3 Interconnection Investment Likely Transferred to Other Counterparties

The evaluations of the 750 MW Interconnection plans assume Manitoba Hydro will be investing in and owning a portion of the US segment of the 750 MW interconnection and that the percentage amount owned stays constant for the life of the interconnection asset. As discussed in Chapter 14 of the NFAT submission, at page 31, it is Manitoba Hydro's intent to arrange for some or all of the Manitoba Hydro ownership to be transferred to another owner for the economic benefit of Manitoba Hydro as soon as an appropriate opportunity can be developed. Mr. Cormie indicated he expects there will be US entities interested in taking over such transmission ownership due to the investor benefits that would accrue and that Manitoba Hydro is in fact in active discussions with a transmission owner who is keenly interested. This would reduce the cost to Manitoba Hydro and increase the net benefits of the plans with the 750MW interconnection.[205]

10.5.4 Interconnection Likely has More Operational Benefits than Captured by Current Modeling

Any modeling of physical or economic systems inherently involve approximations and cannot capture precisely the variety of ways that value can be extracted from those systems. History has demonstrated that Manitoba Hydro's modeling of the generation/transmission system and exports/imports is conservative and does not capture all the benefits associated with expanding the interconnections. Mr. Colaiacovo noted in his evidence that

[204] Transcript, p 2427
[205] Transcript, p.1628

"Optimization is something that you can only do once the assets are actually there. And transmission assets are very flexible and allow you to make optimization decisions after the fact. There is a reason that transmission assets commercially command very high premiums: because you can make money on transmission assets in a variety of different ways."[206]

[206] Transcript page 7295, line 13.

11.0 DROUGHT

11.1 MH Position

Manitoba Hydro's drought management plan is consistent with the requirements of: the Manitoba Hydro Act, and includes elements of the Generation Planning Criteria[207], the Power Resource Plan[208], System Operating Priorities[209], Energy Operations Planning Processes[210], and its Detailed Operating Plans.

11.2 Drought: Keeping Drought from Being an Emergency

La Capra's evidence (LCA Technical Appendix 5, page 5-7) and testimony (Tr. p. 6451-54) suggests that La Capra was not able to find answers to the questions they were asked to pursue in the Manitoba Hydro drought management information they reviewed. Drought management is an integral part of all of Manitoba Hydro's financial and facilities planning and operations; it begins with its legislative mandate to "provide for the continuance of a supply of power adequate for the needs of the province" (*The Manitoba Hydro Act*, Section 2) and culminates with detailed energy operations plans that are prepared weekly. As explained by Ms. Flynn, Manitoba Hydro takes drought very seriously:

> "With respect to Manitoba Hydro's generation planning criteria, Manitoba Hydro has technical criteria for ensuring that the lights stay on, that our homes are warm, and industry continues to hum in the province. This is a responsibility that Manitoba Hydro takes very seriously and that generation planners and systems operators lose sleep over. We cannot underestimate the responsibility that [Manitoba Hydro] has for reliability and dependability of supply to Manitobans." (Tr. p. 1292-93)

Manitoba Hydro's drought management plan, in its most broad form, is the combination of the Manitoba Hydro Act, Generation Planning Criteria, Power Resource Plan, System Operating Priorities, Energy Operations Planning Processes and MH's detailed operating plans.

<u>Planning for Drought: *The Manitoba Hydro Act*</u>

[207]NFAT Application Appendix 4.1 - Manitoba Hydro Generation Planning Criteria.
[208]NFAT Application Appendix B - Manitoba Hydro 2011/12 Power Resource Plan.
[209] Attachment 1 to PUB/MH I-147(a)(ii) of the 2010/11 & and 2011/12 GRA and Risk Review, also included in MH CSI Undertaking #15 Energy Operations Planning – Drought Management.
[210]MH CSI Undertaking #15 Energy Operations Planning – Drought Management.

Manitoba Hydro's planning and operations are governed by *The Manitoba Hydro Act*,

> "The purposes and objects of this Act are to provide for the continuance of a supply of power adequate for the needs of the province, and to engage in and to promote economy and efficiency in the development, generation, transmission, distribution, supply and end-use of power ..." (*The Manitoba Hydro Act*, Section 2)

Accordingly, Manitoba Hydro plans the development and the operation of its system to be prepared for drought.

Planning for Drought: Generation Planning Criteria

Drought preparedness for Manitoba Hydro begins with the Generation Planning Criteria which includes an energy criterion that recognizes the predominately hydro nature of Manitoba Hydro's system. Manitoba Hydro must plan to have sufficient energy in its system in the event of a repeat of the worst drought on the record of 99 years of hydraulic flow data. In its review, La Capra did not raise any concerns with Manitoba Hydro's energy criterion as it is applied to hydro resources, stating "MH's energy criterion requires dependable resources to be available in the event of a repeat of the driest flow conditions, which is generally consistent with other hydro-dependent systems[211]."

Planning for Drought: The Power Resource Plan

The Power Resource Plan is a product of the Generation Planning Criteria.

> "Through the power resource planning process, Manitoba Hydro assesses the need for new resources, reviews potential resource options, and evaluates new resource development plans. The process and results are documented in the Power Resource Plan. The recommendations define the long-term development plan which best ensures that adequate supply resources are available to meet all firm domestic load requirements together with existing electricity export sale commitments." (NFAT Business Case, Chapter 1, page 19).

[211] La Capra Associates Technical Appendix 1 - Resource Planning, page 1-17.

Planning for Drought: System Operating Priorities

As explained in the response to LCA/MH II-461, Manitoba Hydro plans its operations with the guidance of System Operating Priorities. Documented in 1988, those priorities were first filed with the PUB as part of the 2010/11 & 2011/12 GRA and Risk Review[212]. The System Operating Priorities (updated to explicitly include Safety) were also included in the document "Energy Operations Planning – Drought Management" filed as MH CSI Exhibit #15. They are as follows:

1. Safety;
2. Energy Supply;
3. Energy Reserves;
4. Reliability;
5. Citizenship Concerns;
6. Economic Operation

Planning for Drought: Energy Operations Planning

Manitoba Hydro has documented the procedures and processes involved in energy operations planning, including under drought conditions, in the CSI document, "Energy Operations Planning – Drought Management"[213]. The purpose of this document is to outline the factors Manitoba Hydro must consider in maintaining an adequate supply of electricity for its customers in anticipation of and during drought conditions. The document outlines the roles and responsibilities, processes and reporting requirements related to drought. This document also provides guidance on the issues that should be considered in operations planning and operational drought risk management.

Planning for Drought: The "Drought Operating Plan"

The Energy Operations Planning – Drought Management document[214] describes in detail the assumptions behind the Drought Operating Plan. The Drought Operating Plan is a forward looking supply and demand balance – a sequence of planned reservoir releases, generation and import and export activities for a defined set of conservative assumptions. Key assumptions include future water supply conditions, thermal generation availability, wind generation supply, import capability and domestic load.

[212]Attachment 1 to PUB/MH I-147(a)(ii) from 2010/11 & 2011/12 GRA and Risk Review.
[213]MH CSI Exhibit #30, "Energy Operations Planning – Drought Management".
[214] MH CSI Exhibit #30, "Energy Operations Planning – Drought Management".

In essence, the Drought Operating Plan, which is updated weekly, is a detailed supply and demand plan based on conservative assumptions for the remainder of the operating horizon. The Energy Operations Planning - Drought Management document[215] sets out in detail the fundamental requirements of the Drought Operating Plan.

La Capra was provided with The Energy Operations Planning - Drought Management document which was also filed with the PUB as MH CSI Exhibit #30. The operating parameters and many of the assumptions that make up the Drought Operating Plan were also described in the twenty-seven IR responses from past GRAs, which were included in Manitoba Hydro's response to LCA/MH II-461.

Manitoba Hydro Reasonably Addresses and Manages Drought Risk in Resource Planning

Manitoba Hydro mitigates and incorporates drought risks through various steps in the resource planning process. Managing the reliability risk to the energy supply is achieved by adhering to Manitoba Hydro's Generation Planning Criteria, while the financial risk is incorporated into the main economic and financial analyses and studied separately through sensitivity analysis. Manitoba Hydro maintains that while the financial impacts of a prolonged drought are significant, corporate strategies for managing financial impacts of drought are not significantly influenced by the different development plans being studied as the Manitoba Hydro system is a predominantly hydroelectric system and will remain so well into the future.

Manitoba Hydro has the benefit of a long history of streamflows that provides a well-defined hydrologic risk profile which includes significant flood and drought events. Dr. Roy noted that Manitoba Hydro was fortunate to have such a long streamflow record[216]. Manitoba Hydro's economic and financial analysis used for planning, rate setting and financial forecasting purposes benefit from this long record. Manitoba Hydro uses the SPLASH model to simulate system operations for each of the 99 historical streamflow conditions in order to cover the range of possible flow conditions that may occur in any given year in the future. The individual components of the annual production costs and extraprovincial revenues are then averaged over the 99 flow cases to create average annual values based on all of the historical hydrologic conditions, including all historic droughts. The average annual values are then used as Manitoba Hydro's projection of long-term production costs and extraprovincial revenues.

[215] Ibid.
[216] Transcript page 1932, lines 9-13.

In addition to including all historical drought conditions in the expected projections of production costs and extra provincial revenues, Manitoba Hydro has performed an economic sensitivity analysis on the specific occurrence of a prolonged drought[217].

Manitoba Hydro maintains that the five-year historical drought from 1987/88 to 1991/92 modeled in the NFAT submission is both reasonable and appropriate for illustrating the differences in hydrological risks between development plans required to support long-term resource planning decisions.

La Capra initially raised concern with respect to Manitoba Hydro's drought analysis, however, La Capra ultimately supports Manitoba Hydro's position that the 1987/88 to 1991/92 period is adequate for reflecting drought risk when they stated "We examined the -- the effects of a number of different stream flow sequences from the period of record included in this -- in this technical appendix, and showed some of the sensitivity that -- I think that we found -- we didn't find that there was substantial added exposure for extended periods of drought consideration."[218]

Manitoba Hydro's economic analysis of drought assessed the impact of a repeat of the prolonged five-year historical from 1987/88 to 1991/92 on plans with increasing amounts of new hydro generation and interconnections compared to plans with new thermal generation[219].

Manitoba Hydro's analysis shows that in development plans with additional hydro resources, the negative impact of a prolonged drought is incrementally larger than that of development plans with additional thermal generation. This is expected as there is incrementally more projected surplus opportunity revenue when additional hydro resource options are added that will not be realized under drought conditions. Notably, the economics for plans with additional thermal resources, under prolonged drought, are more sensitive to changes in energy prices than plans with additional hydro resources. This is mainly attributable to plans with additional thermal generation having a greater overall proportion of variable fuel costs which are sensitive to energy prices.

Manitoba Hydro has also performed a financial drought sensitivity analysis to explore the impact of a prolonged drought on the Corporation's retained earnings (Chapter 11, Section 11.4 of the NFAT Business Case). Three development plans were used to illustrate the

[217] Chapter 10 NFAT Business Case
[218] Transcript page 6454.
[219] MH Exhibit #125.

impact on retained earnings on varying levels of investment in hydro development and interconnections. Similar to the economic sensitivity of drought, the droughts were applied in the financial analysis over the same range of future start dates and across the energy prices studied. Plans with additional hydro resources are robust in that hydro has the capability to absorb the adverse financial effects of a prolonged drought. At the end of the prolonged drought the retained earnings remain higher and consistently positive with additional investment in hydro development.

A key conclusion from the analysis of drought is that the impact of prolonged drought is a significant reduction in retained earnings regardless of timing of the drought or resource planning decisions. This result is to be expected in predominantly a hydro system as acknowledged by MPA when they state:

> "But as we referred to in our report, if you have, you know, the drought of the century, it doesn't matter which choice you make between the Development Plans of the fifteen (15) plans presented to Manitoba Hydro. If you have the drought of the century, it's a severe blow to Manitoba Hydro regardless of the Development Plan chosen, right, because you have 5,000 megawatts of hydro capacity already mostly on, you know, the same group of river systems."[220]

Overall Manitoba Hydro's development plans which include new hydro resource options are robust in their ability to absorb the incremental adverse financial effects related to drought. Manitoba Hydro submits that it reasonably addresses and manages its exposure to drought.

12.0 RELIABILITY AND ENERGY SECURITY

By having increased access to imports and by having increased domestic generation, Pathways 4 & 5 provide Manitobans with a higher level of system reliability to address generation or major transmission outages or unexpectedly high load peaks. They also provide Manitobans with a higher level of energy security to mitigate unexpectedly severe droughts or unexpectedly high energy consumption (Submission Chapter 14 and LCA/MH I-0037). None of the NFAT participants disagreed with or challenged Manitoba Hydro's evidence in this regard. A number of witnesses concurred that adding interconnection capability is valuable for a number of reasons, one of them being improvement in system reliability.[221] [222] [223]

The measure for grid reliability is the loss of load expectation which is a standard industry engineering technique used to evaluate capacity reliability (Tr. p 1493 lines 4-9). Manitoba Hydro analyzed the different plans and compared system reliability using loss of load expectation. Mr. Wojczynski indicated:

> "when we analyze the plans and -- and determine how much reliability we have, we have a result where the plans with the interconnections and generation advanced for export provide a much higher level of reliability than a plan where you have an all gas plan where you get just exactly the minimum amount of generation and nothing extra" (Tr. p. 1494, line 5).

The Preferred Development Plan with a 750 MW interconnection provides 500 to 1,000 megawatts more load carrying capability (Tr. p. 1494, line 19). Mr. Wojczynski contrasted this with the All Gas plan, wherein he testified: "If you have a gas plan, those gas generators don't bring you anything extra". (Tr. p. 1495, line 6).

Over the 20 years starting with the 2019 Keeyask ISD, should Manitoba experience a drought significantly more severe than the worst drought on record, the 750 MW Interconnection Plans provide significant 3,000 to 6,500 GWh emergency energy imports from Minnesota and Wisconsin to meet Manitoba domestic load compared to the All Gas Plan and Keeyask/Gas Plan.

[221] Power Engineers, Mr. Arnold, Transcript page 6588.
[222] La Capra, Mr. Peaco,Transcript page 5701.
[223] Mr. Bowman, Transcript page 10068.

Manitoba Hydro estimated the benefit of increased reliability to Manitoba electricity consumers from the Preferred Plan relative to the All Gas plan to be $101 Million NPV. The interconnection plans without Conawapa would provide a large portion of these reliability benefits. The additional energy security benefits would be even larger than the reliability benefits (Tr. p. 3701, line 15). The importance of reliability to Manitoba electricity users was confirmed by MIPUG in its Final Argument (Page 40, lines 37-38): "Specifically for MIPUG, the current interconnection and hydro system has generally proven to support the reliability, stability and long-term benefits important to industrials." When the reliability and energy security benefits are added together, they would total more than $200 Million NPV.

In conclusion, the 750 MW Interconnection plans provide a major enhancement to the reliability and energy security of the electrical supply to Manitobans; the benefits to electricity consumers are expected to be greater than $200 Million NPV.

13.0 FINANCE

There has been a significant amount of evidence, and a number of alternative analyses filed during the course of this proceeding. In considering the financial analysis of the PDP and alternatives, Manitoba Hydro focused on comparative impacts on future customer rates, and Manitoba Hydro's comparative exposure to financial risk. Notwithstanding the significant review and exchange on information, Manitoba Hydro finds that its conclusions with respect to the comparative impacts on future customer rates and financial risk have remained largely unchanged from the original NFAT Submission.

First considering the impact on future customer rates, Manitoba Hydro's conclusions with respect to the future customer rates can be summarized as follows:

1) Near-term rate increases in the order of 3.95% are required regardless of the development plan chosen;
2) In the medium term, the Preferred Development Plan is projected to have cumulative rate increases that are generally higher than other alternatives. All other plans evaluated have similar rate increases in the medium term;
3) In the long term, plans with both Keeyask and Conawapa are projected to have the lowest cumulative rate increases. The All Gas Plan and Keeyask/Gas/no interconnection have the highest cumulative rate increases. The plans with Keeyask and the 750 MW Interconnection have significant lower cumulative rate increases than the All Gas Plan and Keeyask/Gas/no interconnection;
4) The Preferred Development Plan is projected to have the lowest cumulative rate increases to Manitoba customers over the long term, supporting the position that an early in-service date for Conawapa should be protected.

Manitoba Hydro's conclusions regarding financial risks will be addressed below.

13.1 The Myth of the 2% Electric Rate Increase in Canada

Electric utilities across Canada are facing cost pressures driving the need for higher than inflationary rate increases. Manitoba Hydro is not unique or alone in this regard. As outlined by Mr. Barnlund in his testimony at transcript pages 2746 to 2749, Canadian electric utilities expanded and built their electrical systems after the Second World War and this infrastructure is now at or near the end of its useful life requiring refurbishment or replacement. The Conference Board of Canada produced analysis that electric utilities across

Canada will be required to invest approximately $350 billion between 2011 and 2030 (MH Exhibit #111, slide 27).

The rate increases sought and approved in other Canadian jurisdictions have and continue to be significantly driven by the need for this specific reinvestment. As Mr. Rainkie stated,

> "That's why the myth of the 2 percent rate increase in Canada is -- is that, a myth." (Tr. p. 3047).

Higher than inflation rate increases are being proposed by other utilities across Canada for 2014 and on. For example:

- BC Hydro rates increased by 9.0% effective April 1, 2014 and will increase by 6.0% in 2015 as directed by the British Columbia government. The rate increases for 2016, 2017 and 2018 have been capped by the BC government at 4.0%, 3.5% and 3.0% respectively;
- SaskPower implemented a rate increase of 5.5% effective January 1, 2014, and has received approval to increase rates by 5.0% in 2015;
- Nova Scotia Power implemented a general rate increase of 3% in 2014, which when combined with increases to the DSM Cost Recovery Rider, resulted in overall rate increases ranging from 3.1% to 4.5% depending on the rate class;
- The Régie de l'énergie approved a rate increase of 4.3% (3.5% for the large industrial customer class) for Hydro Quebec effective April 1, 2014;
- Lastly, in accordance with the Ontario government's 2013 Long Term Energy Plan, residential bills for Ontario consumers could increase by approximately 9.6% in 2014, 5.8% in 2015 and 15.0.% in 2016.

By direct comparison, Manitoba Hydro's projected 3.95% rate increases are moderate relative to other Canadian utilities. Even when considering rate increases approved and proposed by other Canadian electric utilities since 2006, Manitobans continue to enjoy electricity rates that are at or near the low end for rates of Canadian utilities as evidenced by Manitoba Hydro's lower relative current rate index found in the Cumulative Rate Table in Manitoba Hydro's rebuttal evidence (MH Exhibit #85, p.137). MPA stated,

> "fundamentally, you are a Hydro province and you're going to remain that way with all of the benefits that that brings, because it does bring a lot of benefits: the fact that your rates over the last twenty (20) years have been much lower than most other jurisdictions" (Tr. p.7291).

In reviewing the projected annual bill comparisons between Manitoba, British Columbia, Saskatchewan and Quebec over the next 10 years (MH Exhibit #111, p. 30), Mr. Barnlund surmises that:

> "there's no information available to us that suggest that utility costs are going to become dramatically cheaper in other jurisdictions compared to where we are today in Manitoba. So the relative relationship between our rates and those other rates, you know, will not diminish significantly." (Tr. p. 2756, lines 13-19).

As in the past, Manitoba Hydro will continue to balance rate increases with customer sensitivity in a fiscally prudent manner. Furthermore, Manitoba Hydro's current ratepayers will continue to benefit into the future from the low cost past long-term investments in addition to the future long-term investments proposed by the Corporation.

13.2 Near-Term Rate Increases of 3.95% are Required Regardless of the Development Plan Chosen

Manitoba Hydro currently has more than $13 billion worth of assets on its balance sheet which the Corporation must maintain and for which the Corporation must recover costs. Additional investment in Manitoba Hydro's existing assets is required to ensure ongoing safe and reliable service. It is important that rates are increased gradually over this time period in order to provide adequate revenues for the required investment in existing infrastructure, meanwhile avoiding the necessity of seeking higher rate increases in the future.

Even with the addition of development plans, the Manitoba Hydro electric system will be comprised predominantly of existing infrastructure for a significant period of time. As a result, the need for rate increases in the first 5 to 10 years is driven by the need to invest in system reliability enhancements and in aging utility assets that are becoming significantly more costly to maintain and renew. Costs related to development plans are deferred and have no direct impact on rates prior to their in-service dates.

Manitoba Hydro has historically funded base capital expenditures (that is, capital expenditures not related to the development plans) through internally generated funds. However, Manitoba Hydro is now projecting capital coverage ratios below 1.0 until approximately 2016/17, indicating that projected revenues at current rates are not sufficient to fund base capital expenditures. Gradual rate increases are required to ensure Manitoba Hydro is collecting the necessary revenues to maintain its financial sustainability over the long run. As such, projected rate increases of 3.95% over the near term are the minimum rate increases required under all development plans to provide for the necessary investment in infrastructure, and to allow the Corporation to continue to provide safe and reliable service.

Regardless of which plan Manitoba Hydro develops, there are financial challenges in the near term and rate increases are required under all development plans. Mr. Rainkie testified that:

> "…the reality is, in the next five (5) to seven (7) years, there is no new generation source in. We would be asking for the 3.95 percents under the All Gas Plan, as well. In fact, there's more pressure under the All Gas Plan, because we're amortizing some of the sunk costs of Keeyask and Conawapa" (Tr. p. 2774).

This position was supported by MPA at transcript pages 7315 and 7316, wherein MPA describes the relative competitiveness of Manitoba Hydro's projected rates:

> "…regardless of the plan, it includes years of rate increases for a variety of reasons … ratepayers are not going to be happy about many years of increases. But the mitigating factor is that in other jurisdictions there are rate increases as well. Ontario has had nothing but rate increases for the past fourteen (14) years. Quebec is facing rate increases. Newfoundland is facing rate increases. British Columbia is facing rate increases."

13.3 50 Year Time Period Is Appropriate For Financial Evaluation

A 50 year time period was selected for the NFAT financial evaluation to be consistent with the long-term nature of hydro-electricity assets, and to provide a sufficient time frame to analyze the benefits and costs of each development plan recognizing that in all cases the first plant is not in place until 2019, and in the case of Conawapa, the earliest in-service date is 2026. The Electric Operations Financial Forecast was the starting point for each set of pro forma financial statements and was extended to encompass the 50-year study period for evaluation purposes.

13.4 Rate-Setting Methodologies

The August 2013 NFAT submission rate setting methodology assumed even-annual rate increases in order to achieve the targeted debt:equity ratio by the end of 2031/32. Once the debt:equity target was reached, the projected comparative annual rates for the remainder of the 50-year financial forecast period utilized the corporation's interest coverage ratio target of 1.20.

In order to mitigate cumulative losses in the early years of the financial evaluation period and to smooth rate increases in the 2032 timeframe, the April 2014 supplementary financial analysis (MH Exhibit #104-12) provided two additional alternative rate setting methodologies:

1) Maintaining annual 3.95% rate increases in each development plan until 1.20 interest coverage ratio is achieved and rates required to maintain 1.20 thereafter (similar in methodology to MPA financial modeling); and
2) Modifying alternative 1 with rate increases as necessary in the period 2016 to approximately 2022 in order to minimize losses, followed by annual 3.95% rate increases until a 1.20 interest coverage ratio is achieved (and with subsequent rates required to maintain a 1.20 interest coverage ratio).

These additional methodologies eliminated the large decrease in rates that occurred in 2033 as a result of the application of the first rate setting methodology (the so-called "correction factor"). In addition to achieving moderate levels of net income (or minimizing losses), the alternatives provided were in direct response to the discussion between the Chairman and Mr. Rainkie beginning at transcript page 2773 and were intended to aid in the Panel's understanding of the rate impacts without the dramatic changes in rates following the initial 20-year period. The alternative rate methodologies were designed to be more closely aligned to rate changes based on income levels that Manitoba Hydro may propose in practice.

As shown in the following table (excerpted from MH Exhibit #104-12-7), even with rate increases of 3.95% per year using Alternative Rate Method #1, the Plans 1, 5, 6 and 12 result in cumulative losses to 2021/22 of approximately $0.3 to $0.7 billion. It is not until rate increases are raised using Alternative Rate Method #2 to between 4.32% and 5.60% for 5 to 7 years that the cumulative losses are minimized. As noted previously, Plan 4 is considered hypothetical from a business perspective as a 250MW interconnection would require renegotiation of a contract with Minnesota Power and is not likely to be approved by US authorities.

	Main Submission Rate Method Even-Annual Rate Increases	Main Submission Rate Method Cumulative Net Income/(Loss) 2014/15 – 2021/22	Alt. Rate Method #1 Cumulative Net Income/(Loss) @ 3.95% 2014/15 – 2021/22	Alt. Rate Method #2 Even-Annual Rate Increases	Alt. Rate Method #2 Cumulative Net Income/(Loss) 2014/15 – 2021/22
Plan 1	3.36%	$(1,019)	$(688)	5.46% (2016-2020)	$7
Plan 2	3.55%	(504)	(279)	5.60% (2016-2020)	403
Plan 5	3.74%	(550)	(434)	4.60% (2016-2022)	(59)
Plan 6	3.75%	(536)	(426)	4.59% (2016-2022)	(59)
Plan 12	3.76%	(443)	(333)	4.44% (2016-2022)	(53)
Plan 14	4.27%	82	(99)	4.32% (2018-2022)	10

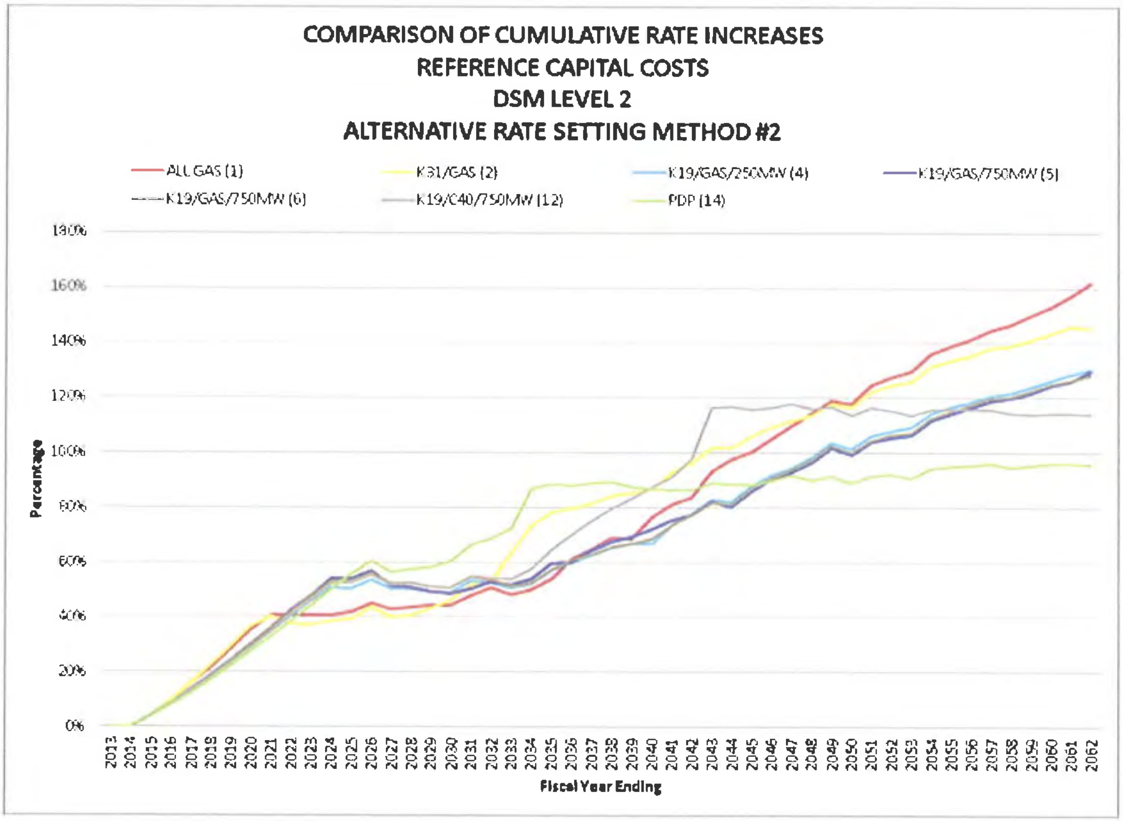
13.5 Projected Cumulative Rates 2015-2062

In the August 2013 NFAT submission, Manitoba Hydro prepared its financial evaluation based on eight (8) of the development plans included in the economic analysis under 27 different combinations of scenario assumptions including economic variables, capital cost and export prices to form 216 distinct sets of pro forma financial statements.

The April 2014 supplemental filing (Manitoba Hydro Exhibits #104-12-1 to 104-12-4) provided an update to two of the plans analyzed in the August 2013 NFAT submission financial evaluation (the All Gas Plan 1 and the PDP Plan 14), along with a new financial analysis of Plan 5 (Keeyask/Gas/750). Manitoba Hydro filed the May 2014 supplemental information (Manitoba Hydro Exhibits #104-12-5 to 104-12-7) to the August 2013 NFAT submission and the April 2014 supplemental filing which included Plans 2, 4, 6 and 12 with DSM Level 2 as well as Plans 1, 5 and 14 under DSM Level 2 with incremental pipeline load.

These plans were updated to reflect 2013 planning assumptions as well as the March 2014 updated capital costs for Keeyask and Conawapa, and consumption savings and utility costs associated with increased DSM (capitalized in a deferral account and amortized over 10 years). The 750 MW US interconnection in the updated Plans 14 and 5 assumes no WPS investment. It should also be noted that the aforementioned updates were made to the IFF12 forecast model used for NFAT evaluation purposes as the IFF13 forecast model was not extended for the 50-year study period. As such, the base capital expenditures (common capital) reflect IFF12 assumptions and there was no update for actual 2013 financial results.

The Figure and Table below show the cumulative rate increases based on alternative rate setting method #2 at DSM Level 2. This rate setting method is reflective of the approach that may be applied by Manitoba Hydro in future General Rate Applications, and as explained in Section 10.3.1, is the level of DSM upon which Manitoba Hydro focused its analysis.



Excerpted from MH Exhibit #104-12-5, p. 2

CUMULATIVE RATE INCREASES AT DSM LEVEL 2 USING ALTERNATIVE METHODOLOGY #2 AND REFERENCE CAPITAL COSTS		
	2031/32	**2061/62**
ALL GAS (1)	51%	162%
K31/GAS (2)	53%	145%
K19/GAS/750 MW (5)	53%	130%
K19/GAS/750 MW (6)	53%	128%
K19/C40/750 MW (12)	54%	114%
PDP (14)	69%	96%

Excerpted from MH Exhibit #104-12-5, p.3

The Figure and Table above demonstrates that:

1) In the medium term, the Preferred Development Plan is projected to have cumulative rate increase of 69%. All other viable plans evaluated have similar rate increases that range from 51 – 54%;

2) In the long term, plans with both Keeyask and Conawapa are projected to have the lowest cumulative rate increases. The PDP at 96% and Plan 12 at 114%. The All Gas Plan and Keeyask/Gas/no interconnection have the highest cumulative rate increases at 162% and 145% respectively. The plans with Keeyask and the 750 MW Interconnection have significantly lower cumulative rate increases in the order of 130% when compared to the All Gas Plan (162%) and Keeyask/Gas/no interconnection Plan (145%).

The Preferred Development Plan is projected to have the lowest cumulative rate increases to Manitoba customers over the long term, supporting the position that an early in-service date for Conawapa should be protected.

13.6 Manitoba Hydro Financial Targets

The alternative rate methods are provided as information to this NFAT proceeding and are in no way an indication that Manitoba has recommended or accepted revisions to its financial targets.

In its final argument at page xii, MIPUG concluded that Manitoba Hydro should adopt lower debt:equity and interest coverage targets for at least the next 20 years in order to mitigate the costs of higher rates and risks associated with higher debt in pursuing a development plan with a Keeyask 2019 in-service date and a 750 MW transmission line to the US. In making this conclusion, MIPUG referenced the alternate rate setting methodologies #1 and #2 that were presented by Manitoba Hydro in MH Exhibit #104-12 as a suggestion that Manitoba Hydro is prepared to significantly yield on the debt:equity target. MIPUG goes on to state at page 46 of its written argument at lines 25 to 28 "There was no opportunity to cross-examine Hydro on these Rate Design Alternatives, so it is not clear the extent to which they truly represent a potential policy decision to yield on financial targets imposed on customers, or are solely a theoretical analytical exercise".

While Manitoba Hydro did not have an opportunity to speak to the alternate rate setting methodologies that were filed towards the end of the hearing, the filing of this additional material arose from a discussion between the Chairman and Mr. Rainkie at pages 3025 to 3032 of the transcript. To be clear, this additional material does not suggest a policy change or yielding of financial targets on the part of Manitoba Hydro as suggested by MIPUG, but rather is a means of providing additional flexibility in terms of the quantum of the rate increases and the "pace" of moving towards the attainment of the financial targets. The alternate rate setting methodology is consistent with the approach successfully used in the past by Manitoba Hydro to promote rate stability for customers while at the same time ensuring the financial integrity of the Corporation.

While Manitoba Hydro may be prepared to accept some slippage in returning to its financial targets beyond 2032, it is only prepared to do so if it is fiscally prudent. Manitoba Hydro had indicated in its rebuttal evidence that:

> "If circumstances such as favourable water flows and sufficient cash flows are present [emphasis added] in the latter part of the 20-year time period, Manitoba Hydro may have some flexibility to taper off the projected even-annual rate increases but this would have the effect of extending the timeframe of achieving the 75:25 debt/equity ratio target" (MH Exhibit #85, p. 136).

It is not clear whether or not MIPUG is requesting the PUB to make a recommendation in its NFAT report that Manitoba Hydro should adopt lower financial targets, or if this is simply a suggested option for future consideration. Manitoba Hydro notes that in Order 43/13, Directive #10, the PUB has directed Manitoba Hydro to review the adequacy of its financial targets and report on this subject to the PUB at the next General Rate Application which is anticipated to be filed late in 2014 or early in 2015. As such, it would be premature for the NFAT panel to make any firm recommendations on Manitoba Hydro's financial targets in advance of the review of this matter by the Manitoba Hydro-Electric Board and the receipt and consideration of this report by the PUB at the next GRA.

MIPUG has also argued that the projected level of retained earnings under each of the development plans is in excess of the amounts required to mitigate the financial effects of a drought (Tr. p. 11236, MIPUG Exhibit #28, p. xii and 76-77). Manitoba Hydro's financial targets were established to aid the Corporation in managing all of the risks faced by the Corporation. While drought is a high impact, high likelihood type of risk, there are others such as a major infrastructure loss that are a high impact, lower likelihood risk but that the magnitude and duration of such a loss could overwhelm the impacts of a drought. If the Corporation faces more than one risk concurrently, the importance of having adequate retained earnings increases. MIPUG's use of drought as a measure of retained earnings adequacy would be insufficient and would potentially expose customers to significant rate increases.

13.7 Sunk Costs

In discussing the issue of sunk costs, MIPUG concluded that the sunk cost calculations favour plans with Keeyask and Conawapa and produce artificially high rate increases to plans without these plants.

Manitoba Hydro stated in the Information Request process that the full amount of sunk costs related to prior spending will likely not be written-off but rather portions of those sunk costs may be written-off periodically as they are deemed to no longer provide future benefit. Manitoba Hydro indicated that a simplifying assumption was made to amortize the total sunk costs over an 18-year period. The choice of a long period, as compared to a shorter period or a one-year period, was intended to achieve approximately the same net income impacts as a series of one-year write-offs for portions of the sunk costs deemed not useful. As a result, the simplifying approach does not skew projected rate impacts in plans with no Conawapa.

Morrison Park Advisors supported Manitoba Hydro's view that sunk costs must be considered in the evaluation of development plans:

> "If however, Manitoba Hydro does not go forward with it, that real money that was spent still has to be addressed somewhere in the Company's financial

statements. And typically it's expensed. It -- it becomes an expense item and in the year or years in which it's expensed, then Manitoba Hydro will have either no profit, or negative profits, or less profit than it otherwise would have, which will have an impact and a consequence on its equity ratio, because it will reduce retained earnings. The -- there is no way around It -- it's real money, real cash that was spent. And so it has to be taken into account somehow....

However, the reality is if you don't go forward with the Keeyask project, you still have to pay the $1.4 billion. So that $1.4 billion loss, if you will, in certain circumstances has to be addressed and taken into account. So is that in some sense unfair to other options? Well, I suppose. If an alternative option only costs $4 1/2 billion and Keeyask all-in costs 5 1/2, once you add the sunk costs of Keeyask onto the other option, suddenly it doesn't look so attractive. Fair or not, that's reality. Right? And that's how you have to address the attractiveness of the different options, because it's what ratepayers have to pay." (Tr. p. 7282-7283)

The Chairman raised a question regarding the potential rate impact associated with proceeding with Conawapa protection in the event that the project is later cancelled. Manitoba Hydro provided a response in MH Exhibit #149.

Based on the projected expenditures in the response to PUB/MH I-238c, the total actual and projected expenditures, including escalation and interest, are approximately $650 million (in nominal dollars) to the end of 2016/17. If at the end of 2016/17 the Conawapa Generating Station was deferred, the Corporation would continue to regard the facility as a potential resource option and would periodically assess whether the costs incurred to date would continue to provide future benefit. Costs which continue to provide future benefit would continue to be deferred and costs which do not provide future benefit would be required to be expensed. If a simplifying assumption is made, similar to the All Gas development plan, where the costs incurred to the end of 2016/17 are amortized over an 18 year period and the debt/equity ratio of 75:25 is achieved by 2032, the impact on rates is approximately an additional 0.07% per year to 2032.

13.8 Cumulative PV of Consumers' Revenue

The primary focus of the financial analysis is on the comparative impact on future customer rates and Manitoba Hydro's comparative exposure to financial risk. Affordability and the distribution of costs and benefits on a year by year basis are also addressed. As part of the

Information Request process, Manitoba Hydro was requested to provide the additional metric of cumulative PV of consumers' revenue. This is only one metric to be considered in the financial analysis. It should be given no more weight than any of the other metrics provided by Manitoba Hydro.

The table below provides the Cumulative PV of Consumers' Revenue based on the updated information.

CUMULATIVE PV OF CONSUMERS REVENUE AT DSM LEVEL 2 USING ALTERNATIVE METHODOLOGY #2 AND REFERENCE CAPITAL COSTS DISCOUNTED AT 1.86% REAL (In Billions)

	2031/32	2061/62
ALL GAS (1)	$26.9	$57.6
K31/GAS (2)	$26.8	$58.5
K19/GAS/750 MW (5)	$27.4	$56.2
K19/GAS/750 MW (6)	$27.5	$56.3
K19/C40/750 MW (12)	$27.4	$58.0
PDP (14)	$27.7	$57.0

Excerpted from MH Exhibit #104-12-5, p. 4

At a real discount rate of 1.86%, plans with Keeyask and a 750 MW Interconnection have the lowest consumers' revenue 50-year NPV. Plans with Keeyask and the 750 MW Interconnection (Plans 5 and 6) are virtually indistinguishable from one another based on a 50-year NPV. Based on the 50-year NPV, the PDP is lower than the All Gas Plan.

While Plans 5 and 6 have a lower NPV of consumers' revenue, the PDP has significantly lower cumulative rate increases by the end of the of study period; 96% versus 130% (shown in MH Exhibit #104-12-5, p.3 above). This supports the position that an early in-service date for Conawapa should be protected.

While Manitoba Hydro accepts that NPV may be utilized to examine consumers' revenues for NFAT purposes (see PUB/MH I-149(a), Figure 11.13, p.6), Manitoba Hydro fundamentally disagrees with applying extremely high discount rates in the determination of the time value of money for customers' bills. Manitoba Hydro demonstrated through cross-examination of MPA (Tr. p. 7564) that a nominal discount rate of 10% translates to an imputed return on equity of 21.1% (assuming a cost of debt of 6.30% and the assumed 75:25 target capital structure in Manitoba Hydro's WACC calculation). At transcript pages 2947 to 2948, Mr. Rainkie refuted the concept of disproportionately high rates of return to customers on revenues paid to Manitoba Hydro for their energy consumption:

> "I guess I've never, from a policy perspective, ever thought that Manitoba Hydro was going to offer a 21 percent rate of return, especially since we don't, in our -- in our actual revenue requirements, we don't follow a rate-based rate of return methodology. We don't charge the customers a 9 or 10 percent rate of return. In fact, if you look at our net income and -- and -- and kind of back calculate that over our equity, we probably charge a 3 to 5 percent rate of return. So, am I going to pay the customer 21 percent when I'm only charging them, you know, 3 to 5 percent in the first -- first instance? That would seem rather perverse. I -- I've never thought of Manitoba Hydro as a financial institution where you put your money and we offer a rate of return. We provide a critical service to Manitobans at a fair cost."

Manitoba Hydro's analysis shows that plans with Keeyask and an interconnection have lower NPV's of customers' bills at a fairly wide range of higher discount rates but plans with Conawapa have lower NPV's at lower discount rates (PUB/MH I-149(a), Figure 11.13, p.6). However, Mr. Rainkie cautioned:

> "... when I impute a 21 percent rate of return and use a 10 percent discount rate, essentially what I'm saying is: I don't really care what happens to, you know, rates ten (10) or twenty (20) years down the line. I'm only worried about the -- you know, the next five (5) or ten (10) years. Because, mathematically, at that type of a discount rate, the -- the fact that -- that you're multiplying any value of it is so small. So, I think what you're doing is actually imputing intergenerational inequity in the situation. You just have to be careful that by jacking up discount rates or truncating evaluation periods, that you're really not just screening hydro-electric power out; the very same fuel that's got us to the -- you know, the favourable rate position that we have right now." (Tr. p. 2949-2950)

Mr. Rainkie further stated:

> "Manitoba Hydro is here, through its mandate, to provide power for the long-term. We have to care about what's happening in the current generation and

the future generation -- future generations of Manitobans." (Tr. p. 2952)

Manitoba Hydro submits that Conawapa should not be dismissed out of hand based on extremely high discount rates applied to analyze the NPV of customers' bills and that plans which include an early in-service for Conawapa should be protected.

13.9 IEC Financial Models

While there may be some benefit in utilizing the third party financial models developed by IECs for indicative initial long term planning purposes, these IEC models are not sufficiently robust to be considered reliable for detailed short-term decision-making or rate setting purposes. MPA confirmed that their financial model was "designed to be indicative and informative in showing directional trends and providing comparative results between development plans and scenario assumptions" (Tr. p. 7542) and not designed to be used for rate setting purposes. La Capra also indicated that the intended purpose of the LCA Dynamic Rates model was focused on the NFAT proceeding (Tr. p. 6334).

In the context of cost of service regulation, Manitoba Hydro has the flexibility to smooth rate increases, which means that at times, not all expenditures that are incurred in a period are passed directly through to customers but rather are deferred to future periods for recovery. When expenditures are not immediately recovered from rates, Manitoba Hydro must fund these cash outflows, typically through debt financing which in turn increases interest expense and consequently future cash requirements. Alternatively, if Manitoba Hydro has surplus cash flow from operations, then the resulting incremental cash flow reduces borrowing that otherwise would have been required, thereby potentially reducing finance expense, future cash requirements and rate increases. Financial modeling must consider these cash flows in order to have validity for revenue requirement or rate setting purposes.

In this regard, Manitoba Hydro concludes that the LCA Dynamic Rates model fails to provide credible financial forecasts and ought not to be used for financial analysis for the purposes of an NFAT process or for rate-setting. La Capra's financial model does not forecast impacts to cash, net debt, or the compounding effects of finance expense impacts resulting from changes to rates, domestic revenues, load forecasts, capital costs, net debt, export sales, fuel and power purchases, or the target value and timing of achieving financial ratios.

La Capra's fundamental omission of these cash flows has a <u>material</u> impact on their modeled results as demonstrated in the comparison of results between Manitoba Hydro's and La

Capra's interest coverage target ratio sensitivity. For example, La Capra's modeling of the interest coverage ratio sensitivity depicts cumulative rate increases of 120% by 2062 (shown in MH Exhibit #167-3, Tab 3, page 9). By comparison, Manitoba Hydro's modeling of the same sensitivity results in cumulative rates of 87% by 2062 (MH Exhibit #167-3, Tab 4, p. 15). This is a cumulative rate overstatement by LCA of 33% (or 0.5% per year for 30 years). On a NPV cash flow basis, the difference between Manitoba Hydro's analysis and the flawed LCA modeled results is approximately One Billion dollars.

La Capra suggests that the differences between the La Capra model and Manitoba Hydro financial modeling are "due to the assumption that cash coming in was not used to change the schedule of paying down debt ..." (Tr. p. 6351). La Capra's model does not incorporate the standard methodology for cash flow analysis. In Manitoba Hydro's view, La Capra's cash flow assumption is a fatal flaw that renders the La Capra model as invalid and unreliable for financial and rate analysis.

The MPA model, while constructed with more sophisticated modeling logic and included the effects of cash flow, also had shortcomings which would limit its use. Manitoba Hydro brought to MPA's attention that MPA's simplifying assumption regarding their interest capitalized calculation would tend to overstate gross interest expense, understate net income, and understate the gross interest coverage ratio in some years. Rate increases in those years would also tend to be overstated. Correspondingly, the amount of stranded debt calculated for the purposes of MPA's illustrative stranded debt analysis would also tend to be overstated in some years.

In summary, while there may be some benefit in utilizing the third party financial models developed by IECs for indicative initial long term planning purposes, these IEC models are not sufficiently robust to be considered reliable for detailed short-term decision-making or rate setting purposes. In Manitoba Hydro's view, La Capra's model is invalid and unreliable for financial and rate analysis. The MPA model, while constructed with more sophisticated modeling logic and included the effects of cash flow, also had shortcomings which would limit its use.

13.10 FINANCIAL RISKS

With respect to Manitoba Hydro's conclusions regarding financial risks, Manitoba Hydro's conclusions can be summarized as follows:

1) In the medium term, development plans with both Keeyask and Conawapa have the highest fixed assets and retained earnings;
2) In the long term, plans with both Keeyask and Conawapa have the strongest balance sheet, with high levels of fixed assets and retained earnings;
3) Development plans with both Keeyask and Conawapa are more robust in their ability to absorb adverse financial impacts in the medium term and extending through to the end of the study period;
4) Net debt levels are converging toward the end of the study period for all development plans.

Manitoba Hydro is embarking upon its developments plans from a position of financial strength. The history of Manitoba Hydro development shows weakening of financial metrics, as measured by the equity ratio, through periods of expansion but recovery following in-service (MH Exhibit #111, Slide 72). The period following Limestone, in particular, shows strong recovery in the equity ratio at a time when rates charged to Manitoba customers did not change largely due to Manitoba Hydro's expanding access to the US export market. Coming from a period with the highest equity ratio in its history, the Corporation is well situated to move forward with its upcoming capital investments with a greater ability to protect ratepayers from sudden or excessively large rate increases.

The following table summarizes the updated projected net fixed assets, net debt, retained earnings and debt/equity ratios as at 2031/32 and 2061/62.

Development Plan	Plan #	(F) Net Fixed Assets	(G) Net Debt	(H) Retained Earnings	(I) Debt:Equity Ratio as at 2031/32	(J) Net Fixed Assets	(K) Net Debt	(L) Retained Earnings	(M) Debt:Equity Ratio as at 2061/62
		As at 2031/32 in Billions of Nominal Dollars				As at 2061/62 in Billions of Nominal Dollars			
All Gas	1	$19.0	$14.5	$4.1	78%	$29.9	$14.5	$10.2	59%
K31/Gas	2	$26.9	$21.5	$4.8	82%	$34.2	$15.8	$12.8	55%
K19 Gas 750 MW	5	$24.7	$19.4	$4.7	81%	$32.7	$15.5	$11.8	57%
K19/Gas/750MW	6	$24.5	$19.2	$4.7	80%	$32.3	$15.1	$11.8	56%
K19/C40/750MW	12	$25.8	$20.5	$4.7	81%	$43.0	$21.5	$15.6	58%
K19 Sales C31 750 MW	14	$36.9	$30.6	$5.3	85%	$39.1	$17.8	$15.3	54%

Extracted from MH Exhibit #104-12-6

As can be seen in the table above, net assets and retained earnings are highest throughout most of the study period under plans with Conawapa. While net debt levels are the highest with the development plans that include Keeyask and/or Conawapa in the medium term, they also have the highest fixed assets and retained earnings.

In the long term, development plans with Keeyask and Conawapa have the strongest projected balance sheet with high levels of fixed assets and retained earnings. Regardless of the development plan undertaken, Manitoba Hydro's system is and will remain predominantly hydro-based and the impact of an extended drought affects all development plans similarly in the near term. The impacts of drought increase over time with Keeyask and Conawapa; however, development plans with both Keeyask and Conawapa generating stations are more robust in their ability to absorb adverse financial impacts in the medium term and extending through to the end of the study period, given their comparatively higher level of retained earnings.

Turning to debt, net debt levels are converging towards the end of the study period for all development plans. The plans with Conawapa have the highest level of net debt in the near term which declines following the in-service of Conawapa. In considering the delayed implementation of Conawapa to 2040 (Plan 12) in the above table, such a deferral leads to this plan requiring a longer period of time to retire its debt. Therefore, Plan 12 shows the highest net debt levels by 2062 relative to the other plans. The All Gas plan has the lowest level of net debt initially but increases throughout the study period and converges with the PDP net debt by 2062 due to the continuous addition of gas facilities.

Manitoba Hydro's debt management strategies are strong. This was evidenced by Moody's in their credit report on Manitoba Hydro wherein they stated that the "view Manitoba Hydro as being capable of prudently managing debt" (MH Exhibit #111, slide 82). This view was also affirmed by MPA when they stated that "Manitoba Hydro has a very sophisticated treasury plan" (Tr. p. 7466, lines 8-9).

As part of this treasury plan, Mr. Schulz described the Corporation's debt management strategy to take advantage of the existing low interest rate environment by securing low interest rate financing that is fixed over an extended period of time. As an example, Mr. Schulz described a recent debt issue secured by Manitoba Hydro with an interest rate of 3.87% fixed over a 50 year term to its maturity in 2063 – thereby eliminating refinancing risk on the debt and reducing interest rate risk within the overall debt portfolio (Tr. p. 2828-2831).

With respect to Manitoba Hydro's borrowings, the Corporation receives a flow through credit rating from the Province of Manitoba. In exchange for this flow through borrowing capability, Manitoba Hydro pays a provincial guarantee fee to the Province of Manitoba which was described as a "fair exchange" from Manitoba Hydro's perspective by Mr. Schulz in discussion with Chairman (Tr. p. 2840-2843).

As Manitoba Hydro makes interest and principal payments to bondholders on an uninterrupted basis, Manitoba Hydro's debt is considered by the credit rating agencies to be self-supporting. To the extent that Manitoba Hydro prudently manages its debt and maintains its self-supporting status, Manitoba Hydro's capital investment plans should have no significant impact on the Province of Manitoba's credit rating (Tr. p. 2828, lines 12-17).

In the response to PUB/MPA I-027(a), MPA introduced a calculation of implied stranded debt in which they address the upper limit of potential unsupported debt. At transcript page 7566, MPA clarified that:

> "So it's a purely mathematical calculation, and it's a theoretical upper limit, and by no means is that a judgment of an actual financial distress situation. It's simply one measurement that was used to indicate for us -- when we were trying to understand how financial distress could conceivably occur, this would be a directional flag for us to look at certain kinds of situations."

On cross-examination, MPA confirmed that Manitoba Hydro's interest coverage ratio includes non-cash items, and if those non-cash items are added back, that Manitoba Hydro has sufficient cash flow to meet bondholder payments to an interest coverage ratio as low as approximately 0.8 times (Tr. p.7567-7568). As a result, MPA's calculation of potential unsupported debt using the 1.20 times interest coverage is flawed.

MPA's final conclusion on the various levels of debt between the plans is that the financial risk is acceptable: "...do any of the levels of projected debt present an unacceptable risk to the province? It doesn't appear so when you go through this analysis." (Tr. p.7513)

MIPUG concurs with MPA's assessment of the risk of debt in its closing submission:

> "the evidence is that this debt is readily manageable, is highly unlikely to lead to any adverse impacts on the provincial credit rating under even extreme adverse conditions (and further even if there were severe financial pressures at Hydro at most a fraction of Hydro's debt would be considered not self-

sustaining - this fraction of debt would remain well within the province's ability to defend to credit agencies)." (MIPUG Exhibit #28, p. 17-18)

The flexible pathways provide Manitoba Hydro with options to manage through future uncertainties. Management has additional options such as cash conservation, deferring spending, bridge financing and rate increases to manage liquidity risk and ensure Manitoba Hydro debt remains self-supporting. As Manitoba Hydro has historically managed adverse conditions, including drought, in a balanced way, the Corporation will continue to do so.

13.11 The Risk of Deferral

Delaying the decision to build to a future decade may not necessarily be cost effective. There is risk that not taking the opportunity to have export customers today help fund the "basement suite" or "apartment building" may result in higher costs for Manitoba customers in the future. As described by Mr. Rainkie,

> "people are trying to set this up as this risky great big hydro plan versus this tiny little gas investment that you make at the – at the front end, which is, of course – slide 61 [MH Exhibit #111] shows you quite a different perspective" (Tr. p. 2811, lines 16-19).

Mr. Rainkie further summarized the evidence which demonstrates Plan 14 has "stable, low-cost larger investments at the front end versus a series of investments under All Gas, but in the end, we end up with the same level of net – net debt and higher levels of equity" (Tr. p. 2812, lines 18-22).

The financial evaluation demonstrated that uncertainty in customer rates is greater in the medium term but lesser in the long term under the Preferred Development Plan relative to All Gas and Keeyask/Gas/750. Variation in escalation and interest rates is the dominant factor in customer rate sensitivity rather than capital costs and export and natural gas prices. Once a hydro facility has been constructed, the cost is relatively fixed. Comparatively in a gas-based plan, the continuous addition of gas facilities throughout the study horizon is subject to inflationary impacts on capital costs.

Although it is tempting to focus on the short-term risks associated with the large hydro-electric investments, one ought to be mindful of the longer term risks of plans with gas or deferred Conawapa. Hydro-electric construction costs are growing at more than the rate of inflation. As described by Mr. Schulz,

> "one could make the argument that there's higher interest rate risk, for instance, in the – in the All Gas Plan as compared to the Preferred Development Plan, particularly at a time when we have a low interest rate environment and we can secure many of the near-term or, you know, about to be near term financings at historically low levels, as opposed to rolling the dice and seeing what happens in the future with all those cascading gas plans that are coming on" (Tr. p 3358-9).

This observation was also reinforced by MIPUG in their final submission when they stated that:

> "the other thing we have to be careful about when we de - defer a plant. If construction is happening now, we know what the interest rates are now. They're low. ... we have to be careful ... to take the conclusion that deferring is always better, because we know with a fair amount of certainty what our debt's going to cost us now, but do we have the same certainty in six (6) or seven (7) years?" (Tr. p 11288-11289).

Similarly, deferring the construction start of Conawapa exposes this project to the same inflationary and interest rate risks. It is wise to take advantage of the existing low interest environment to finance Manitoba Hydro's development plans, as opposed to waiting until a future date when interest rates could be higher. As stated by MPA,

> "we have been for the last five (5) years at a very peculiar point in the long-term capital markets life cycle where debt is very cheap, and long-term bonds are available. And that's great for investors that are seeking cash right now, or have been seeking cash for the last five (5) years. I'm not sure it's fair to assume that those conditions are going to continue to pertain for the next ten (10) or fifteen (15) years" (Tr. p. 7465 lines 9-17).

While the savings to ratepayer costs in plans with Conawapa have diminished with higher capital cost and deferral of Conawapa, it is prudent to maintain the optionality between development plans which may include, and continue, to protect Conawapa given the upside potential. As part of the regular planning cycle, Manitoba Hydro will continue to assess the capital costs and economic, financial and export conditions including opportunities to negotiate additional export sales.

13.12 Affordability Is an Issue of More than Just Electricity Rates

During the NFAT process, a number of Intervenors submitted that Manitoba Hydro's future rate increases as projected in the Preferred Development Plan will disproportionately impact low-income customers. As indicated by Manitoba Hydro during oral testimony, rate increases will be required under all development plans, driven in the next several years by requirements to invest in the reliability of the electricity system (Tr. p. 2773-2775). As a result, all of Manitoba Hydro's customers will be impacted by rate increases, regardless of the plan selected.

CAC expert witnesses, Mr. Stevens and Dr. Simpson, provided evidence in respect of the impact of increases in electricity rates on low and non-low income households in Manitoba. Manitoba Hydro recognizes the issue of low-income rate affordability, but submits that this issue does not have a bearing on the determination of which development plan should be chosen given that rate increases will be required under all plans and will impact all of Manitoba Hydro's customers. Furthermore, as has been the subject of prior General Rate Applications, Manitoba Hydro's legislative mandate does not extend to addressing issues of income distribution or social policy.

Manitoba Hydro's mandate flows from *The Manitoba Hydro Act* and is "to provide for the continuance of a supply of power adequate for the needs of the Province and to engage in and to promote economy and efficiency in the development and the generation, transmission, distribution, supply and end-use of power..." (NFAT Business Case, Ch. 1, p. 1). Manitoba Hydro charges rates adequate to recover its costs of supplying power and has a legislative requirement to charge equal rates to each class of customers, which rates shall be the same throughout the Province. Manitoba Hydro does not and cannot distinguish whether or not a customer is low income in establishing rates for each customer class.

In Manitoba Hydro's respectful submission, issues of poverty and distributional effects are complex and extend beyond considerations associated with indicative electricity price increases. Furthermore, these issues ought to be addressed through the setting of social policy which is within the purview of the government.

13.13 Testimony from CAC Ratepayer Panel

CAC presented a ratepayer panel to offer opinions and some personal information as to the potential impacts of rate increases on the individuals who appeared. CAC has suggested that based on the evidence of these ratepayers that the Board should understand that ratepayers prefer lower rate increases in the immediate term with higher increases coming later, and generally fewer rate increases overall.

Manitoba Hydro acknowledges that payment of utility bills and other expenses are not easy for all customers, however we respectfully submit that the role of the PUB either in General Rate Applications or in this proceeding is to ensure a financially stable utility capable of providing safe and reliable electricity to Manitobans, being mindful of the impacts of rate increases on customers. However, it is not within the mandate of Manitoba Hydro or this Board to take on the role appropriately reserved to the Province of Manitoba to provide social assistance programs directed to low income customers by providing low-income rates or rate subsidies.

Ultimately, Manitoba Hydro concurs with the position expressed by Dr. Simpson at Tr. p 7865 and 7867 that transfers to address affordability of electricity rates should be delivered through income based credits, rather than adjusting rates charged by the utility.

13.14 Testimony from CAC's Expert Witnesses

Mr. Stevens and Dr. Simpson testified that direct subsidies to low income customers are the appropriate way to address distributional issues, not through electricity pricing. When asked about recommendations for mitigation of impacts of rate increases on low-income customers, Mr. Stevens and Dr. Simpson emphasized the use of government income transfer payments to low-income households (April 23, p. 7864). When asked if they have considered conservation rates (or block pricing) to help low-income customers, Mr. Stevens and Dr. Simpson indicated that, while on balance they might help low-income, most of their work suggest that such transfer should be made conditional on income, not on prices, because of the unintended spillover effects on customers that are not low-income. As stated by Mr. Stevens and Dr. Simpson, "if you are concerned about the hardship associated with poverty [...] in households with low-income, that direct transfers are a much wider way of dealing with that then[*sic*] trying to fiddle around with prices which may have all sorts of unintended consequences" (Tr. p. 7867).

Manitoba Hydro generally concurs with MKO that the financial impact of the development plans will affect customer groups differently depending on how these costs are ultimately reflected in rate schedules (MKO Exhibit #7, p. 2). However, matters associated with how costs will be allocated and rates designed to recover the costs associated with the development plan, are matters more appropriately addressed in a future process, such as a

Cost of Service Review or General Rate Application. The MKO recommendations outlined at pages 10 to 18 of MKO's final argument (Tr. p. 11400-11423) have not been appropriately examined and tested in this proceeding. Some of these recommendations are contrary to Provincial legislation, some may be more appropriately addressed in a separate regulatory proceeding, and some are not matters which ought to involve Manitoba Hydro or the Public Utilities Board, but rather are matters to be addressed between the MKO communities and government agencies who have jurisdiction over those matters.

As indicated above, rate increases will be required regardless of the development plan chosen. Manitoba Hydro concurs with Mr. Stevens and Dr. Simpson in that the best way for Manitoba Hydro to assist lower-income customers with respect to the impact of rate increases is through energy efficiency:

> [...] in general terms, any measures that can reduce a low-income household's expenditure on electricity would serve the same purpose. And in that regard, the demand-side management programs that were targeted to low-income households would have the desired effect of making them less vulnerable to price increases of electricity. It would cushion that impact by allowing them to reduce their consumption of electricity [...] (Tr. p. 7880-7881).

Manitoba Hydro continues to provide, through its Affordable Energy Program, sustainable, long-term solutions to customers by improving energy efficiency of their homes which results in ongoing reduced consumption and lower energy bills.

14.0 MACRO-ENVIRONMENTAL AND SOCIO-ECONOMIC ISSUES

The NFAT Terms of Reference stipulate on page 3 the factors that the assessment is to take into consideration including, "The socio-economic impacts and benefits of the Plan and alternatives to northern and aboriginal communities…." and "The macro environmental impact of the Plan compared to alternatives." The Terms of Reference on page 4 goes on to identify a number of items that are not in scope of the NFAT, including:

> "The environmental reviews of the proposed projects that are part of the Plan, including Environmental Impact Statements (these will be conducted through individual processes by the Manitoba Clean Environment Commission ("CEC"), and where possible the impacts of the matters to be considered by the CEC are included in the costs of the projects that are part of the Plan)…and…Historic environmental costs." (PUB Exhibit #2)

With respect to the PDP, an EIS for the Keeyask Generation Project has already been completed and those for the Conawapa Project and the 750MW Manitoba-Minnesota Transmission Project are underway – all have had or will have extensive consultation and regulatory review processes before they are approved. For Keeyask, both environmental and socio-economic issues have been extensively reviewed through both the provincial and federal regulatory processes.

After its review of the Keeyask materials filed by the Partnership, the Canadian Environmental Assessment Agency completed a Comprehensive Study Report (currently on its website for public commentary). It concluded that:

> "…the Project is not likely to cause significant adverse environmental effects when implementation of the proposed mitigation measures, the follow-up program and adherence to conditions and requirements related to the necessary federal permits, authorizations and approvals are taken into account." (Executive Summary, CSR, Page ii) (PUB Exhibit #70)

The Clean Environment Commission, which held hearings on the Keeyask Generation Project starting on September 16, 2013 and concluding on January 9, 2014, issued its Report on Public Hearing in April 2014, and came to the conclusion that:

> "...the Panel is more than satisfied that the record is sufficiently complete for it to offer sound advice to the minister. The Commission will recommend that an environmental licence be issued to the Keeyask Hydropower Limited Partnership for construction of the Keeyask Generation Project. " (Foreward, CEC Report, Page xiii) (PUB Exhibit #69)

The CEC also recommended a number of conditions be attached to the licence "...in order to provide some assurance that the goals of the Keeyask Generation Project can be met without compromising the environment of Manitoba." (Executive Summary, CEC Report, Page xvi) The Keeyask Generation Project was also reviewed by independent assessors from the International Hydropower Association based on its Sustainability Assessment Protocol. The IHA assessment found that 95% of the assessed aspects ranked above the good practice level. The project received the highest possible score on 16 of the 22 topics assessed which is more than any other project officially assessed in at that date world-wide. In fact, during his testimony, Mr. Tyson of Typlan noted:

> "In regard to more global perspectives on best management practices, we -- we reference the Hydropower Sustainability Assessment Protocol. The Keeyask Limited Partnership had a third-party review based on that document, and the results indicated that the project meets or exceeds basic good practice in all of the twenty-two (22) categories studied, and it meets best proven practice in sixteen (16) categories. We note that there are some gaps identified, but all of those gaps can be somewhat rationalized by the fact that there are different regulatory requirements in Canada compared to the rest of the world." (Tr. p. 7013, line 21 to Tr. p. 7014, line 7)

In reviewing the evidence submitted by the Independent Expert Consultants (IECs) and the Interveners, as well as their testimony, a number of interesting issues have been identified; however, in many cases, the evidence either does not look at the macro environmental impact of the Preferred Development Plan (PDP) compared to its alternatives or it addresses detailed topics that are typically the subject of project-specific Environmental Impact Statements (EIS).

14.1 Where is the Macro-Environmental Discussion?

Many of the environmental-related reports have focused on details typical of project-specific environmental assessment, rather than provide what is generally understood to be included in a macro-environmental assessment to assist the panel in its deliberations.

For example, in Mr. Hendriks' report entitled "Evaluating Macro Environmental Impact", he indicates the following as one purpose of his report:

> "...I was requested by the Manitoba Métis Federation (MMF) to review the available evidence concerning the macro environmental impact of the PDP and the alternative Plans, paying particular attention to the requirements of the definition of macro environmental impact provided by the PUB." (Hendriks Report, page 5, MMF Exhibit #15).

His report then goes on to document copious amounts of information from previous NFAT reviews (most of which were completed as part of EISs under CEAA, and provide little to no macro-environmental analysis on alternatives) and on the effects of the generating stations reviewed as part of these EISs. No discussion is actually provided on the macro-environmental effects of the PDP or most of its alternatives. As well, as Mr. Hendriks acknowledged in his testimony on May 12, that he has never carried out an environmental assessment or cumulative effects assessment on behalf of a proponent, nor been to the Nelson River watershed region where major component(s) of the PDP would be developed (Tr. p. 10491-10492).

Mr. Hendriks does provide some commentary on the possible effects and benefits of wind development in his second report, entitled "Evaluating the Macro Environmental and Socio-economic Implications of Additional Wind Resource in Manitoba." While the description of wind development and its possible effects (both positive and negative) is reasonably thorough, the report never actually makes any comparison of these effects to the PDP or other alternatives, nor does it discuss any socio-economic implications beyond the costs of development and related employment and business opportunities.

Most notably, the basis of the socio-economic analysis undertaken by Mr. Hendriks appears to be premised on two assumptions: 1) That wind would be developed in Partnership with Aboriginal groups on the basis of new grant/subsidy programs not yet in place; and 2) That the employment and long-term benefits provided by these developments has been underestimated by Manitoba Hydro.

While it is true that for the purposes of the NFAT, Manitoba Hydro has assumed that it will develop and own these resources, historically, this has not been the case. Wind development in Manitoba has been undertaken by private developers with access to government-based grant and subsidy programs, and the energy produced is then purchased by Manitoba Hydro. Although Mr. Hendriks references several initiatives in other jurisdictions, there are currently no provincially based grant programs in Manitoba to encourage the involvement of partnerships with Aboriginal stakeholders in wind development and, presumably, the costs of such a program if it is to be funded by Manitoba Hydro, would need to be built into the cost per MW of developing wind. Mr. Hendriks also notes that an advantage of wind is its ability to be decommissioned quickly if base load decreases (Hendriks Report, pg. 17). A point that Mr. Hendriks neglects to mention is that development of wind on this premise is unlikely to provide the long-term revenue certainty sought by investors, particularly Aboriginal stakeholders, or the related long-term benefits that come from this revenue source.

Mr. Hendriks has also criticized the employment estimates for wind provided by Manitoba Hydro, suggesting that they are likely to be greater and longer-term in nature than anticipated. The basis for this is a comparison to analysis provided by BC Hydro in its 2013 Integrated Resource Plan and an inclusion of direct, indirect and induced employment. Manitoba Hydro's estimates are based on advice provided by GL Garrad Hassan (GL GH), experts in wind development, and reflect the anticipated employment likely to be generated if wind projects are developed provincially. GL GH is an engineering consultant in the design and construction of wind energy projects in North America and worldwide.

It is important to note that many of the construction jobs associated with wind facilities are highly-specialized, with assembly of the turbines themselves undertaken by individuals trained specifically in the field. As such, it is unlikely that detailed training for neither these jobs nor the mandatory experience to fill them would be fully realized within Manitoba. Other available employment, even if there are Aboriginal employment preferences, is much more limited and primarily involves the development of access roads and pad installation for the towers.

This contrasts greatly with the training, employment and business opportunities available through the PDP. Construction and long-term operations employment associated with the PDP far exceed what is available through wind development. The differences would be even greater if the analysis and comparison were based on a consideration of direct, indirect and induced employment for these different alternatives. As well, many of the skills required and gained through the construction of generation projects are applicable to other job opportunities in northern Manitoba and throughout the province.

It is also notable that Mr. Hendriks acknowledged in his testimony that wind developments are most likely to take place in southern Manitoba, which has far superior wind resources than compared to northern Manitoba. Wind projects developed in southern Manitoba would result in limited, if any, benefits for northern Manitobans, especially northern Aboriginal residents and communities (Tr. p. 10526-10527).

> MR. SVEN HOMBACH: And in your view, if there were to be more wind development in this province, do you see it as feasible for any of that development to take place in northern Manitoba as opposed to in southern Manitoba where it's taken place to date?
>
> MR. RICK HENDRIKS: I do not. The wind resources in southern Manitoba are far superior to those in -- in northern Manitoba, and I wouldn't think that a project in northern Manitoba could compete.
>
> MR. SVEN HOMBACH: And it follows, then, that there wouldn't be any northern Aboriginal benefits flowing from wind projects in southern Manitoba?
>
> MR. RICK HENDRIKS: I would say that would be correct, yes.

Ultimately, it is not clear how Mr. Hendriks reached the conclusion that wind development "supports the maximization of socio-economic benefits for Manitobans, including Aboriginal groups". Using BC Hydro's assumptions, wind is much more costly to develop, typically requires the support of subsidy programs, and provides considerably less employment (both construction-based and longer term) than those realized through hydro generation projects.

Unlike others, Gunn and Olagunju have discussed macro-environmental analysis in their expert report; however, the entire report is based on a literature review. It identifies some potential macro-environmental impacts of hydro-electric generation, natural gas-fuelled generation, wind energy, solar photovoltaic and demand side management (DSM) without ever examining how these types of macro-environmental impacts apply to the PDP or the alternative plans. In fact, they explicitly state in a small footnote of their report the following caution, confirmed again during oral testimony:

> "Note that information provided regarding the macro environmental impacts of various power supply options may inadvertently misinform as it is a high-level review based primarily on academic literature. The intent is to present an objective overview of each and the kinds of environmental impacts each is known to be associated with. The discussion is not context-specific to Manitoba, and may not be up to date with rapid movements in the

> marketplace, especially with respect to wind and solar photovoltaic technologies." (Gunn & Olagunju Report, 2014, p. 15, CAC Exhibit #29)

A good example of this lack of context is the identification in their report that hydro-electric developments have the potential to cause earthquakes, inundation of agricultural areas and resettlement problems. Keeyask and Conawapa are included in the PDP and are the subject of the NFAT, yet they would have none of these types of impacts. This was clearly noted in their responses to IRs, and confirmed in the testimony of Dr. Gunn. (Tr. p. 9272, line to Tr. p. 9275, line 11).

The report also identifies the types of benefits associated with the various types of generation and DSM, although similarly it does not link what benefits would specifically apply to the Plan and its alternatives.

In response to why the actual macro-environmental effects of the PDP and its alternatives were not reviewed, Gunn and Olagunju indicate:

> "The intent of the Gunn and Olagunju (2013) report was not to critique the reported macro-environmental and social effects of the actual Preferred Development Plan and its alternatives: this work was deliberately left to other subject-area experts with specific training in the areas of wildlife, fisheries, human health, etc. Moreover, the macro-environmental deliberations of the PUB were not to duplicate the detailed review of the EIS." (CAC Exhibit #29)

This leaves one to question the utility of their report in evaluating and understanding the PDP and its alternatives. This response is also puzzling given that a "detailed review" comparable to an EIS is not at all what is envisioned – rather a high-level overview of the pros and cons of the different options under consideration and within the context of the Manitoba situation. In fact, in discussing strategic environmental assessment, versus an EIS, on page 10 of their report, Gunn and Olagunju articulate that the benefits of such a process (which presumably they endorse and which is macro in nature) is that it is "Broad focus, low level of detail, non-technical", which Dr. Gunn reiterated in her testimony on April 29, 2014. They then go on to state that:

> "One form of SEA, known as 'policy appraisal', is often used to select among competing policy options when there is a need to determine which is most desirable, rather than to predict with accuracy the physical impacts of subsequent development projects (Therivel 1993)."

Although macro-level environmental analysis is conspicuously absent from most of the environmental reports, virtually all of the authors have spent a considerable amount of time commenting on select aspects of the impacts of hydro-electric development. Notably, very few of the reports mention the benefits of such developments, including the huge benefits they provide in the context of low greenhouse gas emissions, training, employment, business opportunities, capacity and community development benefits for local Cree Nations, and economic benefits for Manitoba and Canada.

The macro-environmental reports, which tend to focus on the negative effects of hydro-electric development, in most cases fail to mention that other options within the PDP also come with their own adverse environmental effects. Again, the exceptions here are Mr. Hendriks, who has provided information on wind development (although no comparison to other options is really provided in the report) and the Gunn and Olagunju report, which specifically notes:

> "All of the power supply options will have profound potential impacts on the environment, and that trade-offs among them are complex." (CAC Exhibit #29).

14.2 All Options Have Environmental Effects

It cannot be lost in this process that all of the options outlined in the PDP and its alternatives have some level of environmental effect. For example, a 100 MW wind farm would produce an estimated 13 tonnes of CO_2 equivalent per GWh (see Appendix 7.3 of Manitoba Hydro's NFAT submission, Life Cycle Greenhouse Gas Assessment Overview and response to NFAT information request CAC/MH I-123a). It would also impact an area between 1 000 and 3 000 hectares and would have adverse effects on birds and bats.

Similarly, the development of natural gas plants requires an increased reliance of fossil fuels, contributing to greenhouse gas emissions. On a life cycle basis a simple cycle gas turbine is estimated to emit 764 tonnes of CO_2 equivalent per GWh, and a combined cycle gas turbine estimated to emit 509 tonnes of CO_2 equivalent per GWh (see Appendix 7.3 of Manitoba Hydro's NFAT submission). These values include the upstream greenhouse gas implications associated with the extraction and production of natural gas. Further detail on this is provided later in this final argument in the section on climate change.

The production and combustion of natural gas also has adverse environmental effects. For example, natural gas development in Alberta causes a variety of environmental effects, which have been summarized by the Government of Alberta as follows:

> "Exploration activities, processing facilities and pipelines can have significant effects on the environment in areas where natural gas is produced. The largest impact results from processing gas to render the raw gas acceptable for pipeline transportation to markets. Processing removes carbon dioxide, hydrogen sulphide, natural gas liquids and water vapour. On average, processing plants in Canada recover almost 99 per cent of the sulphur compounds in raw gas, but the remaining amount is released into the atmosphere as sulphur dioxide. Processing facilities use energy and may also release volatile organic compounds (VOCs). Other concerns arising from natural gas production include sour gas odours, groundwater contamination, waste management, land use, and impacts on wildlife habitat in producing areas."
> (From the Alberta Energy website http://www.energy.alberta.ca/NaturalGas/742.asp)

And as noted by Mr. Wojczynski in his testimony related to caribou:

> "With Gas, there isn't any effect in Manitoba, but there would be in Alberta. As a matter of fact, the federal Species at Risk Act has listed the boreal woodland caribou in the area that there's gas production in there and have cited the oil and gas production as being a major issue for them." (Tr. p. 3610).

It was noted by those who testified that in considering options, like gas, it is important to look beyond our borders to the effects that may result if that option were to be pursued. For example:

From the testimony of Mr. Sabine on April 4, 2104:

> MR. DOUGLAS BEDFORD: And drilling gas wells bring their own set of macro-environmental impacts, do they not?
>
> MR. CRAIG SABINE: They would bring a number of environmental impacts into play, one of which we -- one of which [effects of fracking] we discussed to some extent.

> MR. DOUGLAS BEDFORD: Going to suggest to you with an historical precedent in mind, that in the 1930s, it was popular in many places in the world with respect to the treatment of international issues to take what was known as an isolationist stance, in effect, to say, What happens outside my country or my province is no concern of mine.
>
> But if I turn to the year 2014 and macro-environmental issues, would you agree with me that a similar isolationist stance doesn't sensibly hold in today's world to repeat with respect to macro- environmental issues?
>
> MR. CRAIG SABINE: I would commend this hearing for its -- for its willingness to think about things globally and act locally in that context. I'm not so sure that a generalization of that paradigm of thinking can be made.
>
> Certainly, other provinces in our country think about their energy assets in specific ways that are in the best interests of the borders of their own province, and not necessarily to Manitobans, or the rest of the country, for that matter. (Tr. p. 5452-5453).

From the testimony of Ms. Orenstein on April 28, 2014:

> MS. JANET MAYOR: And while no adverse impacts would accrue to those in the north under an All Gas Plan, you're not saying that there are no adverse impacts to human health from an All Gas Plan, are you?
>
> MS. MARLA ORENSTEIN: No. I think at the distribution of where those effects are and what they are likely to be would be -- would be quite different than the effects that we've discussed in the report up to that point.
>
> MS. JANET MAYOR: So to truly understand the -- the overall health effects of an All Gas Plan, you would have to look at the potential health impacts in southern Manitoba and -- and perhaps across Canada --
>
> MS. MARLA ORENSTEIN: Absolutely, and a full health impact assessment would have to do that. (Tr. p. 9059)

From the testimony of Ms. Gunn on April 29, 2014:

MS. JANET MAYOR: There's been discussion during this hearing, and even between you and I, about the potential impacts of gas fuel generation, such as land fracturing and seismic activity. If you were to look at the impacts of an All Gas Plan, for example, in comparison to the Preferred Development Plan, would it, in your view, be appropriate to consider the impacts not only in Manitoba, but also in those areas where fracking, drilling, gas extraction is taking place?

DR. JILL GUNN: Yes, that would be appropriate. (Tr. p. 9280-9281)

In fact, one of the benefits of the PDP is the ability of Manitobans to ensure that its energy needs are being met through the development of well-planned projects, subject to comprehensive environmental reviews, that incorporate appropriate avoidance, mitigation, compensation and offsetting measures and that include province-specific enhancement measures (e.g., employment preferences for our residents). This was stated well by Mr. Tyson in his testimony:

> We've also identified as part of our socioeconomic review that if the best management practice that is -- that have been implemented for Keeyask are also implemented for Conawapa, the benefits to Northern Aboriginals and Northern communities would be optimized." (Tr. p. 7120)

14.3 IECs and Intervenors Focus on the Micro versus Macro Level Effects

Despite noting that the focus of their reports are on macro-environmental effects, many of the authors suggest the need for detailed environmental reviews, akin to an EIS, or have chosen to focus on providing their own detailed reviews of the Keeyask and Conawapa projects (in some cases, pulling directly from the Project's EIS, or from evidence submitted during the CEC Hearing process).

For example, Mr. Hendriks argued in oral testimony that each component of the PDP and presumably its alternatives should undergo a complete environmental assessment process before being evaluated by the PUB through its NFAT process – something that would be exceptionally time consuming, costly and not all macro in nature:

> MR. BRAD REGEHR: So what you're saying, essentially, is that each component must go through a complete environmental regulatory hearing, and then presumably, those regulatory bodies would have to issue their final reports before the Public Utilities Board can make a decision on the NFAT?

MR. RICK HENDRIKS: Yes. (Tr. p. 10474-10475).

As well, many of the other reports looked at micro-level, detailed environmental effects specific to Keeyask and Conawapa. Setting aside that this level of detail is outside the scope described in the Terms of Reference, it requires either summarizing the huge volume of information that was presented in the Keeyask environmental licensing process, which inevitably results in some level of inaccuracy, or the reliance on only portions of the evidence, which leads to incorrect conclusions. Further, the only project for which this level of information is available is Keeyask since detailed environmental assessments have not been done for the other forms of generation in the alternative plans such as gas turbines or wind farms.

For example, the report from MNP and related testimony contains a number of factual errors, which is understandable given the volume of material reviewed in such a short time frame. Some illustrative examples are provided below for caribou and Lake Sturgeon, respectively. Another example where information from the Keeyask process was presented inaccurately comes from the final argument of Ms. Saunders, legal counsel for the MMF, on May 21. Ms. Saunders mischaracterized the Keeyask public engagement process and the principles that Manitoba Hydro relied upon in making its partnership decisions with the KCNs and this is also discussed below.

Finally, the Consumer's Association of Canada and some of its expert witnesses, as well witnesses for the MMF, have provided evidence in their reports and in oral testimony with respect the past hydro-electric developments and the significance of related environmental and social effects. There are important subtleties associated with the term "significant" within the context of environmental legislation that are also presented below for information purposes.

These inaccuracies highlight the importance of the Keeyask environmental licensing process; its specific focus on the Keeyask Generation Project has allowed a level of rigour to be applied in drawing conclusions on environmental matters that simply cannot be matched based on the level of detail in the NFAT process. And, while out of scope of the NFAT, these issues are clarified below in the interest of having a clear and consistent record.

14.4 Caribou

On page 49 of the MNP report it states that for boreal woodland caribou, "The herd's population is estimated to be less than 3,000 and are listed as a threatened species..." (MNP Exhibit #2) This population estimate is for all of Manitoba, as is clear in the referenced Manitoba Conservation's Recovery Strategy for Boreal Woodland Caribou (2005). As such, it does not apply to the lower Nelson River area because the specialists employed in the Department of Conservation and Water Stewardship currently are of the opinion that there are no boreal woodland caribou in the lower Nelson area. While the KHLP opted to treat the ""summer resident caribou" living in the vicinity of the proposed Keeyask Generation Project Station as boreal woodland caribou in its EIS, and this was done as part of the Partnership's precautionary approach; neither Manitoba Conservation, as noted, through the Manitoba Boreal Woodland Caribou Management Committee, nor Environment Canada, in its 2012 Recovery Strategy for the Woodland Caribou, has listed this group of caribou as a distinct boreal woodland caribou herd.

MNP Exhibit #2, page 54 of this same report goes on to state,

> "Typically, there are fewer caribou present in the region as a result of declining migrations in more recent years and lower population numbers of resident caribou due to low utilization of the regional study area. These findings are supported by First Nations oral record as well as by population monitoring conducted as part of the Keeyask EIS work."

The declining migration noted began in the 1950s and, according to Aboriginal Traditional Knowledge (ATK), these caribou are now returning. There is no mention of lower population numbers of resident caribou in any of the EIS materials, including those produced by the Partner First Nations, and this "decline" has not been supported by environmental assessment studies. Apparently, the change in the 'range' of the migrating herds was confused with the size of the herds. The populations of both the Cape Churchill and Pen Islands caribou have increased since the 1970s (Keeyask EIS, Terrestrial Environment Supporting Volume, pp. 7-63). In fact, as noted by Ms. Pachal in her testimony on March 26:

> And -- and I might mention, last year, when we had our Keeyask infrastructure project going, I think there was thousands -- I can't remember. There's some people in the room who might remember how many thousands of caribou came across at the -- at the Keeyask infrastructure project site. It

> was an amazing thing. Thousands of caribou right in the middle of the construction site. It was quite something to see. (Tr. p. 3886)

Mr. Sabine of MNP also incorrectly stated during testimony that:

> There is risk, however, that the caribou will not respond to that new habitat. There's no scientific evidence that supports that they would use new islands that are generated. (Tr. p. 5275-5276)

Yet, there is ample evidence presented in the EIS and documented in the KCNs' Environmental Evaluation Reports that many caribou do in fact use the islands on Stephens Lake to calve – virtually all of which were created by the development of the Kettle Generating Station forebay which is immediately downstream of Keeyask (Keeyask EIS, Terrestrial Environment Supporting Volume, pp. 7-65, 7-69. See also p. 54 of the Fox Lake Cree Nation Environmental Evaluation Report).

14.5 Lake Sturgeon

The MNP report contains similar inaccuracies about Lake Sturgeon. In section 7.2 of the MNP report on page 59 it states,

> "Manitoba Hydro plans to use stocking as a mitigation strategy to maintain the existing population. It has been suggested by Manitoba Hydro that their conservation stocking program would include either developing another hatchery on the lower Nelson River or using the facilities at the Grand Rapids hatchery. The strategy calls for the genetic integrity and diversity of existing stocks to be preserved. If the option to use the Grand Rapids hatchery is employed, they must ensure local fish are used to supply the brood stock in order to maintain separate genetic stocks." (MNP Exhibit #2).

Stocking being proposed under the Keeyask Project will use brood stock would be used from the same genetic population as the target stocking areas. Although genetic differentiation of populations in the Nelson River has already been established through past studies, research is currently underway to develop a high resolution genetics tool that will provide even greater confidence in delineating genetically distinct populations within the Nelson River (2013 LSSEP Annual Report). All fish brought to Grand Rapids hatchery will be raised using biosecurity protocols that prevent any contact between genetically distinct populations.

Also on page 59 of MNP Exhibit #2, the MNP report concludes,

> "If the project proceeds without lake sturgeon being listed as 'protected' under SARA, there is a risk that populations will not adequately recover after construction, making extinction more likely."

Rather, if the project does not proceed, it is likely that the existing Lake Sturgeon population is not self-sustaining due to the low number of fish and only intermittent recruitment. Listing under SARA would not address the crucial issue of population numbers being at or below a self-sustaining level, which the Keeyask conservation stocking program, including mitigation and adaptive management, is designed to reverse (see Keeyask EIS Aquatic Environment Supporting Volume, Appendix 1A – Part 2).

In Section 7.3.2 on page 60 of the MNP report it states,

> "Lake Sturgeon were once a key source of traditional food for First Nations communities in the area, but this is no longer the case due to drastic declines in the population of this fish since hydroelectric development began in the 1950s...The Keeyask Project is being developed in an area where lake sturgeon have already been impacted negatively by hydroelectric development and remaining populations estimated to be in low numbers." (MNP Exhibit #2, p. 60)

The Keeyask EIS acknowledges that habitat changes resulting from hydro-electric development have likely had a detrimental impact on already depressed populations. However, what is not included in the above quote, is that Lake Sturgeon populations were dramatically reduced due to commercial overharvest before hydroelectric development even began on the Nelson River in the late 1950s (Keeyask EIS, Aquatic Environment Supporting Volume, Section 6.3.1).

On April 4, 2014, in his testimony Mr. Sabine, acknowledges that,

> "Hydro does have a number of substantial mitigation strategies in place in its planning." (Tr. p. 5279, lines 5-6)

He goes on to say,

> "It's difficult to ascertain whether these strategies, which are aimed at preserving and enhancing actually the population, will be sufficient over the long term." (Tr. p. 5279, lines 5-9)

This comment ignores that long term monitoring and adaptive management are essential components of the KHLP approach, as noted in the presentation by Ms. Pachal of Manitoba Hydro on March 25, 2014, (Tr. p. 3594, lines 19-23), and reinforced in the CEC Report through its comments and related licencing recommendations (see Chapter Thirteen, Monitoring and Follow-up of the Keeyask Generation Project Report on Public Hearing).

During Mr. Sabine's testimony, he also posited that,

> "…it's reasonable that passage will be necessary to ensure that the sturgeon are – are able to fill all their – their life stages and requirements for population sustainability." (Tr. p. 5281, lines 1-5).

However, the need for fish passage is site specific. For Keeyask, DFO has determined that:

> "…there is insufficient data at this time to conclude that there is or is not significant upstream movement of fish past the site of the proposed Keeyask generating station…The requirement for fish passage facilities will be determined by the DFO, in consultation with MCWS, based on the results of monitoring, established fisheries management objectives and support for ongoing fisheries productivity." (CAC Exhibit #45-11, Tab 2, DFO letter to KHLP, July 12, 2013)

Mr. Sabine also stated that,

> "…habitat fragmentation and loss, and the loss of spawning habitat particularly at Birthday Rapids, Gull Rapids, and Gull Lake will have an impact on the populations of sturgeon in the Kelsey to Kettle reach." (Tr. p. 5278, lines 15-19).

This is another example where summarizing from an extensive body of information has resulted in inaccurate reporting. The Keeyask EIS concluded that flows at the spawning habitat at Birthday Rapids will be affected, but it is uncertain if it will affect spawning. If monitoring identifies an effect, mitigation measures will be taken and these have already been identified by the Partnership. And while the habitat at Gull Rapids is suitable for spawning, studies have not found evidence of spawning taking place in recent years, which may be a reflection of the present, low population numbers. No Lake Sturgeon spawning habitat was found in Gull Lake itself. (Keeyask EIS, Aquatic Environment Supporting Volume, Section 6).

In fact, the Manitoba Lake Sturgeon Management Strategy (Manitoba Conservation and Water Stewardship, Fisheries Branch, 2012) makes the following observation:

> "The experience of managing lake sturgeon in Manitoba has shown that limiting mortality is the single most effective means of sustaining lake sturgeon stocks. The failure to do this effectively during the latter part of the 1800s and the early part of the 1900s in the historical commercial fishery led to dramatic declines that left lake sturgeon stocks throughout most of the province in the state they are today. Protecting habitat is also important but lake sturgeon in several parts of the province have demonstrated that they can adapt to fairly severe habitat alterations while proving unable to adapt to excessive levels of harvest." (MH Exhibit #162, p. i)

14.6 The Engagement of Partners and Others

In her final argument for the MMF, Ms. Saunders contends that,

> "...Manitoba Hydro seems to arbitrarily determine on what projects and with what Aboriginal communities it will apply its proactive approach to, even when there are a number of other Aboriginal communities, including the Manitoba Métis community, in the local and regional study areas of the Keeyask project, and certainly in the Conawapa and Manitoba-Minnesota Transmission Project areas." (Tr. p. 1182, lines 5-12).

> "So we think that the headway that Hydro has made with respect to its KCNs in going from the Northern Flood Agreement to the JKDA will only be undermined if it continues in this generation in pursuing these projects, to continue to deny another Aboriginal people that same opportunity to be a part of something that will directly impact them." (TR pg. 11217, lines 6-12)

It is well known that the Keeyask Generation Project is being developed by a Partnership involving Manitoba Hydro and four Cree Nation communities. The decision to partner with these First Nations on Keeyask, and any future decisions with respect to partnering on new developments, are business decisions made by the Corporation. In making these decisions, a number of factors are considered, including, but not limited to:

- Manitoba Hydro's obligations under existing settlement agreements;
- The vicinity of a community to the project;
- The potential for these communities and their members to be adversely affected by its development; and
- Historical and contemporary use of the project area by community members for traditional purposes.

Perhaps most importantly, the company also considers whether it is reasonable and makes good business sense to enter into a partnership for a particular project. For example, in her testimony on March 25, Ms Pachal noted with respect to transmission that:

> Manitoba Hydro has the authority under the Act to structure transmission arrangements. We've used that authority to structure those arrangements in the best interests of Manitoba ratepayers, and as such Manitoba Hydro retains 100 percent ownership of all transmission assets in Manitoba. (Tr. p. 3584-3583).

Based on the considerations above, a business decision was made to partner with the four Cree Nations on the Keeyask Generation Project. These communities all have historical relationships and existing settlements with Manitoba Hydro, they are those most affected by the Project's development, and are those resident in and using those areas most affected by the Project. To date, no other party, including the Métis, have demonstrated that they have a direct interest in the area where the Keeyask Project is to be built (see MH Exhibit #183). In the case of the Métis community, Aboriginal rights of the Métis are not recognized by the courts, the Provincial or the federal government in Northern Manitoba, unlike southern Manitoba. Those Manitobans who self-identify as Métis and who wish to hunt in northern Manitoba are required to purchase hunting licenses just like non-Aboriginal hunters.

Despite this, the Partnership made explicit and concerted efforts to involve others, including the Métis, in planning for the Project, through its Public Involvement Program (PIP). The PIP was intentionally designed to be extensive and thorough and provided opportunities for participation and input throughout Manitoba. In developing the PIP, the Partnership sought to apply the following principles consistently in all of its activities:

- Accessible process;

- Opportunities at key stages
- Transparent and open
- Use of a variety of communication mechanisms
- Engagement with Aboriginal peoples, and
- Responsive and adaptive

In fact, after several rounds of IRs and several weeks of hearings, including extensive evidence and debate on the involvement and participation of the Métis and others, the CEC in its Report on Public Hearing concluded the following:

> "Efforts were made to consult with other communities beyond the KCNs and they appear to have been relatively thorough. A large number of communities, NGOs, First Nations, Aboriginal organizations and individuals were provided with the opportunity to question the Proponent, raise concerns about the Keeyask Generation Project and have these concerns documented within the supporting material for the EIS. After review of the Proponent's public consultation process, as requested by the minister, the Commission is of the view that the process was comprehensive, inclusive and more than met the requirements for consultation." (CEC Report on Public Hearing Keeyask Generation Project, April 2014, p. 37)

A similar approach will be used to guide public engagement processes for future development projects in the PDP, building on the lessons learned from Keeyask and other recent developments. This should provide comfort to the PUB and others, that the engagement efforts made by the Corporation on its developments are sound and represent best practice in this field.

14.7 Engagement with the MMF

Detailed information on the engagement of the Métis in the Keeyask Generation Project, and the potential effects of this Project on the Métis, were thoroughly reviewed in the Keeyask CEC Hearing and through the s.35 consultation activities undertaken by the federal and provincial governments.

The topic of engagement with the MMF was discussed at length during the Keeyask CEC hearings, the details of which can be found on pages 39 through 48 of MH Exhibit #183 filed in this proceeding by Mr. London.

It is notable that in this hearing the MMF did not put forward a single witness, or ask any of the Manitoba Hydro witnesses questions, related to the engagement of the Métis in the planning for new development projects outlined in the PDP. This would have provided a similar opportunity for all of those involved in the NFAT process to review and test the assertions put forward by the MMF in its final argument - assertions that were vigorously tested during the Keeyask CEC process, and that lead the CEC to the conclusion cited above.

Since 2004, over 150 meetings that have addressed Keeyask in some way have taken place with the MMF. For the purposes of clarifying the record, and for addressing the assertions advanced by the MMF in its final argument, the following summarizes the special engagement processes implemented to seek the input of the Métis, through the MMF, in the planning process for the Keeyask (more detail is provided in MH Exhibit #183 and in the Partnership PIP filings):

- The MMF was involved in processes related to Keeyask from a very early stage as a participant in the Hydro Northern Training and Employment Initiative, beginning in the early 2000s. Testimony on their engagement was provided at this hearing and confirmed that they received a portion of the funding from this initiative and participated on the Board of Directors of the consortium responsible for implementing the training program.
- The MMF and its members were invited, and encouraged, to participate in the PIP and special arrangements were offered to support their participation – however, these offers to the MMF were refused in all but Round 1 of the three round program.
- After five years of negotiation and over 30 meetings, in June 2013 Manitoba Hydro (on behalf of the Partnership) and the MMF reached an agreement on a work plan and budget for the MMF to undertake a Métis-specific Keeyask Traditional Land Use and Knowledge Study (TLUKS), an historical narrative for the Keeyask Region and a Socio-economic Impact Assessment documenting the potential impacts on the Project on the Métis. The Partnership has always committed to reviewing and discussing these studies with the MMF once they are complete and to modifying or enhancing mitigation measures, if required, based on study findings. The results of these studies were due in October 2013. Manitoba Hydro has agreed three times to extend the Contribution Agreement and, to date, has only received a brief historical narrative. The MMF did present preliminary results of the TLUKS at the CEC Hearing, and these results confirmed the following:
    - The traditional area of Métis use recognized by the provincial government and agreed to with the MMF does not extend to the Keeyask Region. This means that any hunting, trapping or fishing activities undertaken by Métis in the Keeyask area are

done through licences issued by the provincial government. Licensed harvest activities and associated mitigation are well documented in the Partnership's EIS.

- The majority of resource use undertaken by Métis residents in the region takes place in areas near Thompson and Thicket Portage – areas not affected by the Keeyask Project and also outside of the traditional region identified through an agreement between the MMF and Manitoba.
- There is very little, if any, use of the Keeyask region and mitigation measures planned by the Partnership to address resource use activities are robust and apply equally to Métis residents of the region.
- There is no persuasive evidence of a historical Métis community in the Keeyask region whose descendants continue to live and/or use the region today, contrary to what was stated by Ms. Saunders. According to the Supreme Court of Canada, it is the existence of this type of Métis community which gives rise to the Métis rights identified in s.35 of the Constitution

For other projects, Manitoba Hydro has and will continue to attempt to engage with the MMF to review, discuss and understand the potential effects of new developments on Métis living in or using resources near to these projects. With respect to the MMTP, initial engagement of stakeholders is now taking place and the MMF have been invited to participate in this process.

The potential effects of a Project on the exercise of Treaty and Aboriginal rights is specifically assessed by the Province of Manitoba and by Canada under their duty to consult with Aboriginal groups as per Section 35 of The Constitution Act. These Section 35 duties have not been delegated to Manitoba Hydro and are different and distinct from Manitoba Hydro's obligations as a project proponent. For the Keeyask Project, the federal s.35 process is complete and the provincial process is near completion. The MMF was engaged in both of these consultation processes. Manitoba Hydro is generally not privy to the outcomes of these consultation activities, but it is notable that the Comprehensive Study Report completed by the federal government did not find any concerns with respect to Métis rights and interests in the Keeyask area.

14.8 The "Significance" of Past Developments

Finally, much has been said at the NFAT hearing about the effects of and lessons to be learned from past developments.

Ms. Pachal testified on March 25, 2014:

> "So Manitoba Hydro, as you've heard, prior to Wuskwatim planned and developed projects in a much different way than we do today. Our past projects, while in line with contemporary practices of the time and consistent with government requirements, involved much less consultation than would be considered acceptable today and considerable -- considerably less upfront planning with respect to environmental concerns.
>
> And as a result, environmental effects were not always fully understood in advance. And related avoidance, mitigation, and enhancement measures were not always identified and implemented in advance of project construction, and nor were they typically included in the capital project estimates.
>
> The planning and development processes for today's projects are very different, as you've heard many times this morning. The project planning process involves early and extensive engagement with communities in the vicinities of these projects, particularly the Aboriginal communities. And there is a concerted effort to prevent and reduce as much as possible potential impacts through improved project design and implementation of project mitigation and community-based programming.
>
> Efforts are also made to enhance project benefits as much as possible, especially for local communities, through measures like income oppor -- opportunities, training, employment, and business opportunities." (Tr. p. 3572-2573)

Witnesses for the CAC and the MMF talked extensively about Manitoba Hydro's past developments and their legacy. For example, the foundation of Mr. Hendriks' report is a suggestion that the best way to understand possible macro-environmental effects is to review effects experienced in other watersheds for comparable projects. Manitoba Hydro agrees with this approach, but would note that such a comparison needs to be context-specific – both in terms of the environments and the nature of the projects being proposed. For this reason, considerable efforts are undertaken to understand the possible effects of new developments based on a review and understanding of the outcomes of past hydroelectric developments within northern Manitoba. In fact, this is well documented in the Keeyask EIS, with ample discussion documenting relevant lessons learned from the Kelsey, Kettle, and Long Spruce generating stations and Notigi control structure, and the effects of the Churchill River Diversion and Lake Winnipeg Regulation Projects. Many areas affected by these earlier developments are used as proxies for understanding the possible effects of Keeyask (for example, Stephens Lake was used in the Keeyask EIS for several aquatic parameters including water quality and ice cover (Keeyask EIS, Executive Summary, pp. 22-24) and would also be used to understand the possible effects of Conawapa.

Oddly, the report by Mr. Hendriks criticizes the nature of the information provided in the Keeyask EIS –

> "My review indicates that the EIS and environmental evaluations describe the adverse nature of the effects of the prior development in very general terms and provide overall perspectives on the implications of these effects for use of the affected lands and waters." (Hendriks Report, pg 20 – MMF Exhibit #15).

This is a very broad generalization for a reviewer who discloses at the outset of his report and again in oral testimony (Tr. p. 10479-10488) that he has read only the aquatic portions of the EIS and it appears he did not read even those very thoroughly. In fact, the aquatic, terrestrial and socio-economic environment sections of the Keeyask EIS discuss historical change as a result of previous hydroelectric and other developments in the Keeyask Region. In the case of the terrestrial environment, these changes are quantified (because it is feasible to do so), and were discussed in detail through the CEC Process (for example, see the response to CEC Rd 2 CEC-102c, which quantifies change in terrestrial habitat and several related indicators over time for all developments in the Keeyask region).

Mr. Hendriks also states on page 22 of his report that,

> "My review of materials on the company website confirmed the existence of some programs designed to monitor environmental quality in the existing reservoirs. However, these programs do not seem to be designed with the overall intention of understanding the residual environmental effects of the existing facilities." (MMF Exhibit #15)

In fact, Manitoba Hydro and Manitoba have established a Coordinated Aquatic Monitoring Program (CAMP), in cooperation with Manitoba Conservation and Water Stewardship, to study and monitor the health of water bodies affected by Manitoba Hydro's generating system. CAMP's objective is to determine the health of aquatic environments and track them over time by:

- Monitoring the important physical, chemical and biological components of selected water bodies within Manitoba Hydro's generating system.
- Monitoring water bodies outside of Manitoba Hydro's hydroelectric generating system. These off-system water bodies will help determine how other factors, like climate, affect the aquatic environment.

Manitoba Hydro is also very fortunate that it has been provided the opportunity to work directly with many communities located in the vicinity of its proposed new projects. These communities have been affected by past developments and are those most affected by possible future hydro-electric developments. They have a wealth of knowledge about what has been experienced as a result of earlier developments and, based on this, what can be anticipated with future developments. For the KCNs, this knowledge is documented in the Keeyask EIS through their own Environmental Evaluation Reports and has informed many of the mitigation measures for this Project, most notably the adverse effects agreements.

In its report on the Keeyask Generation Project, the CEC made specific note of the positive contribution of ATK and the Keeyask Cree Nations' environmental evaluations, in particular:

> "The Commission found that the three KCN evaluations added greatly to an understanding of the Keeyask Project and to the environmental, historical, cultural, social and spiritual context of the Project. In addition to documenting the experiences and knowledge of members of the communities that will be most affected by the Project, these three reports provided a better idea of how the KCNs came to their decisions to participate in Keeyask and how they put forward issues of great importance to them. They added immeasurably to the ability of Panel members to consider the holistic nature of impacts to the environment of the Lower Nelson River. The reports presented a range of views regarding the Project – pro and con and mixed – and this helped the Panel to better understand the relationship between hydroelectric development and neighbouring communities." (PUB Exhibit #69, page 59).

The knowledge gained through CAMP as well as numerous post project environmental reviews, combined with the experience and knowledge of local Cree Nations, provides a solid, relevant foundation that has been used to understand the potential macro-environmental effects of the PDP.

On the topic of past projects, Gunn and Olagunju also make comments in their report about the effects of past hydro developments, stating on page 40 that,

> "The Nelson sub-watershed has already been substantially altered by hydroelectric development, and it is agreed past alterations have been cumulatively significant." (CAC Exhibit #29, p 5, 13 and 39).

This was repeated by Dr. Gunn in her testimony on April 29, 2014, when she stated:

> So we know that <u>significant</u> stress has already been experienced in -- in that region over the fifty-five (55) plus years of hydroelectric development that's gone on. All those kinds of effects are -- are well documented through the Keeyask hearing, through the Bipole III hearing, and elsewhere. But it is important to note that both Manitoba Hydro and the Keeyask Cree Nations partners, you know, have agreed along with -- with others, including independent experts like myself, that the Nelson River sub-watershed has already been substantially altered and has sustained significant environmental impacts. (Tr. p. 9224)

It is important to note that this is a conclusion that she has personally arrived at, despite also indicating that she has not studied the area extensively or even visited the Nelson River region, has never undertaken a cumulative effects assessment and that the report prepared did not critique the PDP and its alternatives because "this work was deliberately left to other subject-area experts with specific training in the areas of wildlife, fisheries, human health, etc." (Tr. p. 9119, line 7 to Tr. p. 9121, line 8 and Tr. p. 9272, line 2 to Tr. p. 9275, line 11).

Mr. Williams, legal counsel for the Consumers' Association of Canada, similarly used the term significant with respect to the PDP when he stated in final argument that,

> "There are going to be significant adverse consequences for the communities." (Tr. p. 11118, lines 15-17)

Setting aside the fact that the Terms of Reference identify historic environmental and social costs as outside the scope of the NFAT, it is notable that Gunn and Olagunju and legal counsel for their client have chosen to use the term "significant" – a term they understand and know has a very specific meaning in environmental regulatory processes and one discussed at great length during the course of the Keeyask CEC Hearing Process.

Under the Canadian Environmental Assessment Act, a number of specific factors must be taken into account when determining the "significance" of a project on selected Valued

Environmental Components ("VECs") within the context of environmental law. These include factors such as the magnitude, geographic extent, and duration and frequency.. It is important that the term significance – as it is used in environmental law – not be confused with the everyday use of the word. For example, the everyday definition of significant from the Merriam-Webster online is, "large enough to be noticed or have an effect: very important: having a special or hidden meaning". Based on the macro-level review being undertaken by the PUB and the explicit exclusion of project-specific EISs in the Terms of Reference, it is this everyday use of the term that is most appropriate to the PUB's review. Applying this common language definition of significant, past hydro-electric developments have had a profound impact on the environment and people of Northern Manitoba. This was noted in the Keeyask Clean Environment Commission (CEC) hearings on October 24, 2013 by Ms. Vicky Cole,

> "I think what's become very clear during the course of opening presentations, what is acknowledged in the EIS, it's talked about through the Keeyask Cree Nation environmental evaluation reports, is that -- and I'm now going to use the everyday common use of the term, that there is no doubt that these projects have had a significant impact on the communities that we're working with." (Tr. p. 833, lines 17-26).

However, federal and provincial regulators who assessed the Keeyask Generation Project EIS and were obligated to apply the professional, and obviously technical, interpretation of the word significant, found no significant adverse effects following their review of the detailed cumulative effects assessment undertaken by the Partnership.

14.9 Macro Environmental and Socio-Economic Conclusions

In preparing its submission, Manitoba Hydro took care to observe the definition of macro-environmental and socio-economic effects in the NFAT Terms of Reference and in PUB Order No. 92/13 along with items that are identified as being out of scope of the review. It provided appropriate and relevant information on the macro-environmental and socio-economic effects of the PDP and its alternatives in Chapters 13 and 15 of the NFAT submission. Additional information was provided in IRs such as CAC/MH I 231a and MMF/MH II 040a and associated testimony during the hearing. The results from the analyses undertaken by Manitoba Hydro demonstrate that the PDP and the plans with Keeyask and the 750 MW Interconnection provide superior benefits in terms of income, training, employment, capacity and community development, and business opportunities, especially for northern and aboriginal communities in Manitoba over the alternative plans. No compelling evidence has been presented during the course of this hearing that demonstrates otherwise.

The fact that this NFAT process includes consideration of the macro-environmental and socio-economic effects of the PDP and the alternative plans should be applauded as this level of analysis is not typical of many NFAT reviews. Including the consideration of those effects in the NFAT provides the opportunity for the Panel's recommendations to be informed by more than just economic and financial implications of the PDP and its alternatives. As noted above, it is important to remember that this is not the only environmental review these projects will receive. Detailed and thorough environmental assessment and licensing processes will be undertaken for all of the projects, including Conawapa and the MMTP, as they are advanced, and these projects will not proceed unless they also receive the necessary approvals through those processes. These reviews will properly examine the important issues that have been touched on by the NFAT IECs and Interveners in their submissions including cumulative effects assessment, the significance of effects and the details of direct and indirect effects to land, water, air, flora and fauna and the socio-economic environment.

It is notable that the Clean Environment Commission recommended that the Keeyask Project be issued a licence to proceed and that the Canadian Environmental Assessment Agency found that this Project would have no significant adverse effects with the implementation of the Partnership's follow-up program. This Project was planned by Manitoba Hydro and the same Cree Nation communities that will be involved in the planning and development of the Conawapa project. The same level of detail and rigour will be applied to planning and developing that project.

We would like to close this section by reminding the Board of some of the important statements made by Manitoba Hydro's Cree partners in the Keeyask Generation Project.

From Karen Anderson of Fox Lake Cree Nation:

> "Projects like Wuskwatim, Keeyask, and potentially Conawapa move us into a new era where we can strengthen our communities and do business in ways that we could have not done without those avenues." (Tr. p. 3538)

From Ted Bland of York Factory First Nation:

> "York Factory First Nation chose to support Keeyask, not just so our people could benefit from employment, business, and investments opportunities. York Factory chose to become a partner so we could have a voice in how the project is developed and managed. We want to be on the inside and influence the project." (Tr. p. 3559)
>
> "We have entered into the partnership insisting on a long-term ongoing commitment to healing, reconciliation, mutual respect, and self-determination. We intend to sustain our Cree values, customs, and traditions in the process." (Tr. p. 3560).

From Victor Spence of the Cree Nation Partners (Tataskweyak Cree Nation and War Lake First Nation):

> "I have a whole text here that I could read, but the words of my people are in my heart. It hurts many times when we chose as people a path where somehow there are others that seems to question how an Indian should think, how an Aboriginal should talk and make choices for their own people. We chose as a nation, a sovereign nation, a members of a nation. We are not merely objects within the hydro operational system. We are people. We cry. We feel pain. We have needs to better housing, better education, better healthcare services for our people, our Elders, our youth.
>
> That is why TCN choose the path it did in regards to do this development. If it was based on economics, solos -- just solely on economic, we would have said, No, to Keeyask or any development, but it gave more. It provides hope. An opportunity to say, We are involved. We continue to be involved. There's a new vision." (Tr. p. 3565 3566).

15.0 SUSTAINABLE DEVELOPMENT

The NFAT Terms of Reference direct the Board to consider, "The alignment of the Plan to Manitoba's Clean Energy Strategy and the Principles of Sustainable Development as outlined in *The Sustainable Development Act*."

The policy alignment of the PDP was confirmed by both Manitoba Hydro witnesses and independent expert consultants during the hearing.

With respect to alignment to the principles of sustainable development, Mr. Brandson, the only witness who had expertise in the history, development and implementation of the legislation, indicated that Manitoba Hydro has embraced sustainable development and acted to integrate the concept into its daily operations, as well as future planning and development. (Tr. p. 3636, lines 9-12). Appendix 14.1 of the NFAT filing presents each principle and guideline in the order they appear in the act and Manitoba Hydro provides data and examples for each principle. Further, one whole chapter in the environmental impact statement of the Keeyask partners was devoted to documenting the alignment of the project with sustainable development legislation and with Manitoba Hydro's sustainable development code of practice (Tr. p. 3637, lines 6-10).

Norm Brandson testified that "the province has articulated its strategy to achieve sustainability in a particular sector in fairly concrete measureable terms. The provincial clean energy strategy is an example."[224] In evidence, Mr. Brandson also specifically asked the question "How does the proposal before the panel align with the principles of sustainable development contained in the Manitoba Sustainable Development Act"? Manitoba Hydro submits that the summary for each principle provided by Mr. Brandson on Tr. p. 3637-3641 provides the information this panel requires in order to answer this question:

> "Principle 1 is the integration of environmental and economic decisions. As documented in the NFAT submission, and identifying its Preferred Development Pran -- Plan, Hydro screened sixteen (16) resource options against fifteen (15) characteristics divided into four (4) categories: technical, environmental, social and policy, and economic. A melding of environmental, social, and economic concerns was thus incorporated at the earliest stage of planning. The needs assessment cast a wide net that included clearly articulated assumptions for load growth, domestic and export, demand-side

[224] Transcript page 3634, lines 16-19.

management, and existing resources. As options were reduced, the multiple account cost benefit analysis was applied to take into consideration consequences not reflected in a simple accounting of revenues and expenditures.

Principle 2, stewardship. Consideration of the potential impact on future generations loomed large in the thinking of the Keeyask/Cree partners. Throughout the decade long process of developing the partnership measures were agreed upon designed to minimize the impacts and maximize the benefits to future generations. For example, a considerably smaller project than the maximum technically feasible design was agreed upon to greatly reduce flooding. Environmental effects agreements were concluded that ensure ongoing future benefits to the communities. The development of renewable hydro power minimizes greenhouse emissions to the benefit of present and future generations.

Principle 3, shared responsibility and understanding. The Keeyask partnership is founded on respecting the culture, customs, and world view of the Tataskweyak Cree Nation, the War Lake First Nation, the York Factory First Nation, and the Fox Lake First Nation. Aboriginal traditional knowledge had a significant role in the environmental assessment of the Keeyask Project and will continue to loom large in the various plans that will govern the operation of future facilities. Ways to help alleviate the current economic disparity between northern and southern Manitoba have been factored into the plan. To the wider Manitoba public, Hydro has provided numerous opportunities to be informed about the development of its plans and to make their views known. As a Manitoba Crown Corporation, all Manitobans are its partners.

Principle 4, prevention. An initial guiding principle in the planning process was to focus on river systems currently managed for hydro-electric developments. The size of the Keeyask proposal and the preliminary design for the Conawapa development have both been reduced from technically feasible maximum in order to avoid and reduce potential adverse environmental and social effects due to reservoir flooding. Recognizing that predictive science is not infallible, the principle of adaptive management will be applied to Keeyask and Conawapa projects.

Principle 5, conservation and enhancement. The construction of the projects is governed by strict rules to minimize the disruption to terrestrial and aquatic habitat due to construction activities. Lake sturgeon has received considerable attention related to the Keeyask Project. The goal is to enhance the local population through a stocking program. Efforts will be closely monitored and adaptive measures taken if necessary. And opportunities to enhance fish habitat will also be implemented.

Principle 6, rehabilitation and reclamation. All construction-related disturbance not associated with the operation of the hydro-electric plants at Keeyask and Conawapa will be re-vegetated and returned as closely as possible to pre-development conditions. Adaptive management measures again will be implemented to deal with any unforeseen effects.

And finally, and in conclusion, Principle 7, global responsibility. By developing renewable hydro-electric power, Manitoba Hydro will be, through export sales, replacing future greenhouse gas emitting fossil fuer -- fuel power plants. This will contribute to the long-term mitigation of effects of climate change, the most serious global intergenerational issue of our time. Once the power is required to meet Manitoba needs, it will contribute to the province's stated goal of a fossil fuel free Manitoba economy."[225]

So is Manitoba Hydro's PDP aligned with Manitoba's Clean Energy Strategy and the Principles of Sustainable Development as outlined in the Sustainable Development Act? Yes, it is well aligned.

The Consumers Association of Canada (Manitoba Branch) has submitted a document to the Manitoba Public Utilities Board's Need For And Alternatives To Assessment of Manitoba Hydro's preferred development plan and alternatives, entitled Framework for Sustainability Assessment authored by Dr. Kyrke Gaudreau and Dr. Robert B. Gibson. The response to this paper, the concepts contained therein and subsequent oral testimony at the PUB NFAT Hearings is organized around three key questions:

1. Is the sustainability assessment framework (SAF) proposed by the CAC mandated by the *Manitoba Sustainable Development Act*?[226]
2. Does the proposed framework fall within the terms of reference issued to the Public Utilities Board Need For and Alternatives To (NFAT) Panel?

[225] Transcript pages 3637-3641).
[226] It is only necessary to deal with this issue with respect to the *Sustainable Development Act*; if the framework is supported by the Act no further support is required from the *Environment Act* and if it is not so supported it is not reasonable to infer that the *Environment Act* which uses language almost identical to the *Sustainable Development Act* could provide such a mandate; the *Canadian Environmental Assessment Act* does not apply to the present PUB NFAT process and therefore is not relevant.

3. Is the proposed framework widely accepted as an assessment methodology for major development initiatives in Canada?

15.1 Is the proposed sustainability framework mandated by the Manitoba Sustainable Development Act?[227]

The Gaudreau/Gibson Sustainability Assessment Framework Paper (hereinafter referred to as "the Gibson Framework") asserts that:

> "it is clear that there is substantial and significant overlap in the substantive requirements for sustainable development between the generic sustainability criteria and the three Acts" (CAC Exhibit #20, Tr. p. 54).

There is in fact overlap in language between the framework and the Act. This is not at all surprising given that a common vocabulary of sustainable development has emerged over the 27 years that have elapsed since the government of Manitoba first embraced the concept of sustainable development. But there is no overlap in requirements. Language is very carefully chosen in the drafting of legislation. Concerning the substantive subject areas of sustainable development the Manitoba Sustainable Development Act – passed by one government and endorsed by its successor –is uniformly permissive, not prescriptive, and uses adjectives that are intended to allow for flexibility in interpreting if and how the principles and guidelines are applied to individual projects. Examples from the Principles and Guidelines contained in the Act include:

- Economic decisions should adequately reflect environmental, human health and social effects. [Principles 1(1)]
- Environmental and health initiatives should adequately take into account economic, human health and social consequences. [Principles 1(2)]
- Manitobans should (a) maintain ecological processes … (b) harvest renewable resources on a sustainable yield basis (c) make wise and efficient use of renewable and non-renewable resources [principles 5]
- Efficient use of Resources – which means (a) encouraging and facilitating development and application of systems for proper resource pricing … [Guidelines 1(a)]
- Public Participation – which means (a) establishing forums which encourage and provide opportunity … [Guidelines 2(a)]

[227] Background testimony, Norman Brandson, March 25/14 beginning Transcript, p. 3628.

- Access to Information – which means (a) encouraging and facilitating the improvement and refinement of economic, environmental, human health and social information [Guidelines 3(a)]
- Integrated Decision Making and Planning – which means encouraging and facilitating decision making and planning processes that are efficient, timely, accountable and cross-sectoral … [Guidelines 4]

The substance of what the government of Manitoba considers to be at the heart of sustainable development is clearly intended to be flexibly applied and directional, not prescriptive. Nowhere do the words must or shall appear in the Principles or Guidelines. Whenever these words are used in the Act they apply to administrative rather than substantive measures. The words Principles and Guidelines themselves connote an approach that is far more discretionary than command and control. This distinction between prescriptive and permissive is a critical issue in the drafting of legislation. To suggest that the Legislature of Manitoba intended to imply that sustainable development be implemented through the application of prescriptive criteria, but inadvertently neglected to mention it in the legislation, while never sanctioning a process to develop such criteria, completely ignores how legislation in general is, and the Sustainable Development Act in particular, was developed.

The New Democratic government of Premier Pawley embraced the concept of sustainable development when it accepted the 1987 report of the Canadian Council of Resource and Environment Ministers (CCREM) Task Force on Environment and Economy[228] and proceeded to implement its recommendations. This included the passage of the Manitoba Environment Act. In May of 1988 this government was succeeded by the Conservative administration of Premier Filmon. The Filmon government not only confirmed the province's commitment to sustainable development but also identified it as a flagship initiative. A Sustainable Development Coordination Unit was established as a central agency of government. The Manitoba Round Table on Environment and Economy[229] was directed to manage a highly public process to develop sectoral sustainable development strategies for Manitoba.[230] The Sustainable Development Unit also developed a White Paper on the

[228] *Report of the National Task Force on Environment and Economy* submitted to the Canadian Council of Resource and Environment Ministers – September 24, 1987.
[229] The National Task Force had recommended that "Round Tables on environment and economy" (the phrase "environment & economy" was eventually replaced by "sustainable development") of opinion leaders be established in every province and territory and by the federal government. All jurisdictions established these but today almost all have either been eliminated or fallen into disuse.
[230] The Task Force Report recommended all jurisdictions prepare a "Conservation Strategy"; Manitoba's component strategies included Land & Water (Water, Soil, Forests), Capital Region, Waste Minimization, Energy and Minerals.

possible content of sustainable development legislation. The Legislature ultimately adopted a *Sustainable Development Act* in 1997, the substance of which remains in today's Act.

The fact that government, while enthusiastically embracing the concepts of sustainable development, has had considerable difficulty in articulating how to implement its concepts, is evidenced by the flexible approach taken in the legislation, and by the launch of the Consultation on Sustainable Development Implementation (COSDI) to further examine the question in 1997[231]. The Filmon Government was replaced by the New Democratic Government of Premier Doer in October 1999. The Doer administration acknowledged the COSDI report and accepted in concept the nested planning scheme recommended by COSDI, which resulted in the East Side Planning Initiative as Manitoba's first Wide Area Plan. But the government did not pursue any of the recommendations relating to the development of more specific sustainable development evaluation criteria.

A further review of the *Manitoba Environment Act* in 2002-2003 offered yet another opportunity for discussion of more concrete criteria for sustainability to be built into that legislation. Again government declined to pursue such a course and retained the discretionary language contained in the *Sustainable Development Act*. So to suggest that the *Sustainable Development Act* implies a mandate for the SAFP framework and criteria, when government was well aware of this approach to SD implementation and has not chosen to pursue it, is to make an assertion not supported by the evidence. To argue that the flexibility designed into the Principles and Guidelines accommodates and even mandates the development of ninety criteria based on these Principles and Guidelines as the test of acceptability for Manitoba Hydro's proposed development plan, is to ignore the history of the development and application of the Act.

The Gibson Framework states that:

> "...Gibson's framework explicitly states that contribution to sustainability should be prioritized as an overarching goal, and applied at all stages of decision making and planning. The Acts are less explicit in this regard, although they implicitly require a higher test, ...
>
> Likewise the intent of the Environment and SD Acts to ensure the long-term sustainability of Manitoba and its citizens is evidence that sustainability is a long-term overarching goal..." (CAC Exhibit #20, page 55).

[231] Report on the Consultation on Sustainable Development Implementation (June, 1999).

Even if one agrees that indeed "sustainability is a long-term overarching goal" of the Manitoba government it does not follow that the means of achieving that goal is the application of the Gibson framework in this case at this time. This is an example of confusing means with ends.

As noted above, government has explicitly ruled out the adoption of sustainability criteria at this time, and the language of both the Sustainable Development and Environment Acts makes it clear that sustainability is a balance of several not always compatible attributes that preclude a hard and fast "rule" that sustainability shall be the pre-eminent test of acceptability. It is one factor and an important one but at this stage in the development of our sustainable development thinking we lack the societal consensus needed for it to be the litmus test of acceptability.

In his testimony, Dr. Gibson stated:

> "And the basic sustainability wisdom is you can't get towards sustainability by balancing. Balancing is about sacrificing economic or social or ecological objectives. And since they're all completely independent [sic – interdependent] sacrificing any one of them is sacrificing the whole to some extent."[232]

In fact, the concept of sustainability is itself all about balancing.[233] Where possible, positive social, economic and environmental benefits are sought for all development; but this is not always possible. In fact if this is to be the test of acceptability, then a substantial portion of the development upon which the functioning of our modern society rests, would fail.

In defense of the conclusion that the framework is mandated by the *Sustainable Development Act*, the Gibson Framework states:

> "Since both the substantive and procedural requirements of sustainability assessment are already consistent with what is established in the Acts, adoption of a more explicit and more fully elaborated framework for sustainability assessment would be a useful next step in clarifying expectations and facilitating implementation." (CAC Exhibit #20, page 55).

[232] Testimony, Dr. Robert Gibson, April 29/14, Transcript page 9186, lines 10-15.

As noted above, the agreement on substance refers to the use of common sustainable development vocabulary in the legislation and the framework. There is general agreement on the broad components of sustainability. There is certainly no agreement whatsoever on "procedural requirements".

The Gibson framework requires the application of sustainability criteria to be used as the final arbiter on project acceptability; the Act requires that the elements of sustainable development should be (not must be, or shall be) considered, their application encouraged and facilitated. It may well be that government may decide that development of a more rigorous framework for the implementation of sustainable development would be useful, in which case, as it did with the development of both the Sustainable Development and Environment Acts, an extensive and inclusive public consultation process would be undertaken to inform the development of a framework that would have enormous implications for future development in Manitoba. Consultations leading to the *Sustainable Development Act* transpired over almost three years. The COSDI process ran for about a year and a half.

Finally, it should be noted that where government has determined that there is sufficient consensus to better define some of the broad concepts of sustainability, such as social equity, and open, accessible and transparent decision-making, it has developed regulatory and policy instruments governing their application. Examples include the Province's Aboriginal training, employment and business development policies, and various regulatory requirements for access to information, and intervener funding. The Manitoba Energy Strategy is an explicit statement by the government of the people of Manitoba concerning a sustainable energy future for the Province – a fossil fuel free future – and how to get there.

15.2 Does the proposed framework fall within the Terms of Reference issued to the Public Utilities Board NFAT Panel?[234]

The Gibson Framework states that … "the NFAT Terms of Reference (TOR) also require consideration of sustainability concerns". This is correct. The Terms of Reference also are quite specific as to the focus of this consideration. In assessing Hydro's plan:

> The assessment will take the following factors into consideration:
> b. The alignment of the plan to Manitoba's Clean Energy Strategy and the Principles of Sustainable Development as outlined in the *Sustainable Development Act*.

[234] Testimony, Norman Brandson, March 25/14, beginning Transcript page 3635.

In assessing Hydro's plan as compared to potential alternatives, the identical language is employed to describe how sustainability is to be considered.

We must assume that the wording of the TOR was chosen with care. The PUB will take into consideration the alignment of the plan to the Principles of Sustainable Development as outlined in the *Sustainable Development Act.* This language in no way implies that the Principles should be the preeminent test of acceptability. In fact the TOR directs the Panel's attention to the highest, most general level of consideration of sustainability, the Principles; the Guidelines, also contained in the *Sustainable Development Act* are pointedly not included. This level of generality certainly does not support the notion of the development and application of prescriptive sustainability criteria to the assessment of Manitoba Hydro's plan.

Therefore it is reasonable to conclude that the proposed Gibson sustainability assessment framework falls outside of the panel's Terms of Reference.

15.3 Is the proposed framework widely accepted as an assessment methodology for major development initiatives in Canada?

The Gibson Framework relies on "the literature", experience outside of North America, and the work of the World Commission on Dams[235] to demonstrate the acceptance of the proposed framework as best practice. The paper cites some Canadian examples where sustainability has been considered in the project assessment – as indeed it has been considered in the development and assessment of Manitoba Hydro's preferred plan – but it appears that in only one case, the MacKenzie Valley Gas Project, has the Gaudreau-Gibson framework been applied[236]. The analysis utilizing the framework is contained in 32 pages of the 600-page report. It is worth noting that the Joint Panel adopted the SAF approach without direction from the governments, and that its report was filed twenty-five months after the conclusion of public hearings. The Panel stated in its report that … "The Panel cannot stress too strongly the importance of the phrase subject to the full implementation of the Panel's recommendations. Absent such implementation the Panel does not expect the project to make a net positive contribution to sustainability, or to justify approval and permitting." Nonetheless, the governments rejected several recommendations and only conditionally accepted many others. The Panel then withdrew its endorsement of the project and the

[235] Dams and Development – A New Framework for Decision-Making: World Commission on Dams (2000).

[236] Foundation for a Sustainable Northern Future: Report of the Joint Review Panel for the MacKenzie Gas Project (2009).

governments concluded, "The governments stand behind their assertion that the implementation of the final [government] response will eliminate or mitigate any significant adverse effects of the project."[237]

It is neither at all clear exactly what the experience has been outside North America, nor what application it might have in the Canadian context, and a simple assertion that the sustainability assessment framework approach has been accepted in parts of Europe, Asia and Australia cannot be taken as evidence that it constitutes best practice for project reviews in Canada, let alone that it should be applied to the PDP for the NFAT analysis.

The "literature" cited is largely academic, and although of possible interest if and when Manitoba examines a more prescriptive approach to sustainable development, it cannot be said to demonstrate best practice. It is necessary to look to what is actually practiced by the authorities in Canada responsible for major development review to determine best practice; and to date no government in Canada has adopted the sustainability assessment framework approach in assessing development initiatives.

The approach used in the Gibson Framework has defined ninety sustainability criteria that are to be applied to each alternative to determine the preferred alternative (or to propose or define some other alternative). The criteria – many of which are not quantifiable – are to be taken altogether, because of the interrelationships amongst them, and applied at all stages of development planning. "These criteria are specified for this particular case alone and have never been applied by anyone."[238]In order to apply the criteria the "desired future" must be defined. It is further asserted that not only is there no "best practice" in the development and application of a sustainability assessment framework, there may never be a "best practice"! "No there isn't a best practice that's clearly established … there will never be a … a fully defined approach."[239] A framework would have to be constructed anew in each and every case. All of this hardly adds up to a methodology, lacking as it does objectivity, reproducibility, and broad societal input into defining the values inherent in many of the criteria. And it must be emphasized that the SAF is not being proposed as a simple checklist, an additional tool in the assessment toolbox; it is being proposed as the basis upon which a final decision on a preferred development plan must rest. "The centre of it is that we're talking about a positive contribution to sustainability as the essential test on whether proposed undertakings are worthy of approval."[240]

[237] Governments of Canada and of the Northwest Territories Final Response to the Joint Review Panel Report for the Proposed Mackenzie Gas Project – November 2010.
[238] Testimony, Dr. Robert Gibson, April 25/14, Transcript page 9134, lines 4-6.
[239] Testimony, Dr. Robert Gibson, April 29/14, Transcript page 9304, lines 12-13.
[240] Testimony, Dr. Robert Gibson, April 29/14, Transcript page 9127, lines 8-11.

As noted above, it is intended that the framework criteria are to be applied at every stage of project and system design and development. This poses a problem as this particular set of 90 criteria have never been previously applied anywhere. "…one of the challenges that the criteria you are proposing create … we [PUB] would be called upon to … retrospectively apply criteria to a project that … where those criteria were not used to design the project to begin with."[241] "…what Manitoba Hydro has done in this case is quite a bit closer to the standard that we are proposing than most other cases we have seen."[242]

The most widely quoted source in the Gibson Framework is the World Commission on Dams. It should be noted that:

- The Commission's work is somewhat out of date. Its report was completed in 2000 and the actual contents developed over several years prior to that date.
- The Commission relied heavily on case studies. None of these looked at Canadian experience and the only North American example was Hoover Dam, a depression era US project several times larger than any existing or potential Manitoba projects.
- The Commission examined projects in countries where corruption was endemic, democratic, participatory review processes were non-existent and planning at best rudimentary; this had a strong influence on the focus of its assessment.
- The report does not reflect contemporary Canadian practice whereby many of the issues related to the planning for and construction and operation of hydroelectric dams are addressed in standard practices supported by legislation and institutional infrastructure.

Finally, the Manitoba Law Reform Commission has recently initiated a public review of Manitoba's Environmental Assessment and Licensing Regime. In the Commission's consultation prior to preparation of a discussion paper the topic of sustainability assessments was considered. The Commission stated its considered conclusion on this topic in its discussion paper:

> "In the Commission's view it is not yet possible to identify a best practice of sustainability assessment. Moreover, the adoption of a sustainability assessment framework would represent a significant policy choice, involving new forms of knowledge, different participants and a change in focus." [243]

[243] Discussion Paper: Manitoba's Environmental Assessment and Licensing Regime – Manitoba Law Reform Commission (January 2014)

Sustainable Development Conclusion

In conclusion, although it is fair to say that the dialogue surrounding sustainability assessment is stimulating thinking about how to better define sustainability, democratically elected governments in Canada have not yet obtained consensus on many of the broad components of sustainability. This is reflected in the fact that sustainability assessment is not supported by the Manitoba Sustainable Development Act, and that the Terms of Reference issued to the Manitoba PUB NFAT Panel mandate consideration of sustainability in the broadest, high level, non-prescriptive terms leading to the conclusion that a sustainability assessment does not fall within the TOR. And it also fair to conclude that sustainability assessment, even as a concept, is not only not best practice in Canada, but is not "practice" at all; and that the specific framework proposed in the SAFP relies on authority that does not support the assertion that it is a widely accepted methodology.

Manitoba Hydro has, as Mr. Brandson testified, embraced sustainable development and acted to integrate the concept into its daily operations, as well as future planning and development, and has aligned its PDP with Manitoba's Clean Energy Strategy and the Principles of Sustainable Development as outlined in the *Sustainable Development Act*.

16.0 ENERGY AND CLIMATE POLICY ALIGNMENT

Manitoba Hydro's Preferred Development Plan (PDP) offers the strongest alignment with current and expected international, Canadian, US and regional/local climate change policies and strategies. To a lesser degree development plans featuring Keeyask (without Conawapa) and the 750 MW interconnection are also well aligned while development plans reliant on natural gas generation are generally misaligned.

Greenhouse gas (GHG) emissions are facing increasing constraints in the US and Canada through federal regulations and state/provincial legislation.[244] These policies have the potential to increase future fossil fuel generation costs, increase demand for lower-emitting resources, and deliver more favorable market prices for low- and non- emitting resources. Hydroelectric generation provides a hedge for both Manitoba Hydro and its US customers against the cost and risk associated with these current and emerging policies.[245]

16.1 Manitoba Policy Context

The NFAT Terms of Reference direct the Board to consider, "The alignment of the Plan to Manitoba's Clean Energy Strategy and the Principles of Sustainable Development as outlined in The Sustainable Development Act." CAC and MIPUG echoed this direction, further recommending the Board consider factors that go beyond economics, including the "extent of consistency with provincial Government policy and objectives (e.g., Clean Energy Strategy) and national Government policy and objectives (e.g., long-term commitments to reduce Greenhouse Gas Emissions)."[246]

Norm Brandson testified that "the province has articulated its strategy to achieve sustainability in a particular sector in fairly concrete measureable terms. The provincial clean energy strategy is an example."[247]

MNP confirmed the strong alignment of the PDP to existing and future climate policies in both their evidence and direct testimony:

> "By and large, the preferred plan's consideration for resource conservation, sustainable energy development and avoidance of contribution to ongoing

[244] Panel II Direct Evidence (Energy Policy & Pricing Trends in MISO), NFAT Chapter 3.
[245] NFAT Chapter 6, Page 11.
[246] Response to Interrogatory Request CAC/MIPUG I-2.
[247] Transcript page 3634, lines 16-19.

> human-driven climate change increases the attractiveness of the projects in comparison to most of the alternative plans studied as part of the NFAT. The preferred plan also provides the most upside value in a policy scenario that explicitly merits the avoidance of carbon emissions and provides mid-continent regional benefits that support reduction of the continued reliance on more intensely emitting forms of generation."[248]

Mr. Bowman of InterGroup agreed that protecting the option to build Conawapa through the planning and licencing phase is consistent with the Clean Energy Strategy.[249]

MNP concluded that, "The preferred plan more strongly aligns to the current and expected international, Canadian, US and regional/local climate change policies and strategies."[250]

Sustainable development has already been reviewed in Section 15.0 Consideration of both the domestic and global GHG implications and their effect on Climate Change are fully aligned with these principles. Mr. Brandson provides the following comments in regards to Principle 7 – Global Responsibility:

> "By developing renewable hydro-electric power, Manitoba Hydro will be, through export sales, replacing future greenhouse gas emitting fossil fuer -- fuel power plants. This will contribute to the long-term mitigation of effects of climate change, the most serious global intergenerational issue of our time. Once the power is required to meet Manitoba needs, it will contribute to the province's stated goal of a fossil fuel free Manitoba economy." (Tr. p. 3640-3641).

Manitoba Hydro's hydroelectricity exports offer customers a hedge against future GHG emission constraints. Development plans which include natural gas generation are viewed as misaligned with current policies and exposed to future policy implications. Manitoba's Clean Energy Strategy recognizes the clear advantages of hydroelectric generation over natural gas generation; reduced reliance on imported fossil fuels, significantly fewer GHG emissions (See Section 17.6 in the Final Argument entitled The Preferred Development Plan Delivers the Greatest Greenhouse Gas Reductions), fuel price stability, and energy security[251].

16.2 North American Policy Context

Concern over environmental implications and climate change impacts are increasingly driving policy decisions. Under the Copenhagen Accord, both Canada and the US committed to reduce GHG emissions to 17% below 2005 levels by 2020.

The Obama Administration continues to pursue its energy and environmental objectives through regulations promulgated by its Environmental Protection Agency.[252] In the near term, the most consequential current regulation is the Mercury and Air Toxics Standards (MATS) which requires reductions in mercury and other air toxins from coal- and oil-fired power plants. Along with MATS, the Cross-State Air Pollution Rule, Coal Combustion Residuals Handling Regulations and Cooling Water Regulations will increase environmental compliance costs for generators. In May 2014, the White House released its third National Climate Assessment[253] which outlines the effects of climate change on the United States and sets the stage for the expected June 2014 release of EPA regulations to limit carbon emissions from existing power plants.[254] Ultimately, these regulations could have a transformative impact on the US electricity sector.

The Canadian Federal Government is similarly taking regulatory action to address emissions on a sector-by-sector basis through Environment Canada.[255] In addition to the existing Reduction of Carbon Dioxide Emissions from Coal-fired Generation of Electricity Regulation, Environment Canada is currently discussing regulations to limit emissions from natural gas-fired power plants. Plans that include gas-fired generation, MNP suggests, are at risk of facing difficult future Canadian performance standards and could face carbon pricing penalties which would decrease the margins they could earn in export and domestic markets.[256]

Several provinces and states have taken legislative action to limit emissions. A group of eastern states established the Regional Greenhouse Gas Initiative (RGGI), a regional cap-and-trade program. Quebec and California have also established and linked cap-and-trade programs. Other actions include: Alberta has an emission intensity reduction program, British Columbia has a carbon tax, and Nova Scotia set a hard cap on GHG emissions from its electricity sector.

[253] MH Exhibit #191-1.
[254] MH Exhibit #95, page 67.
[255] Chapter 3, page 17.
[256] MNP Report, page 15.

Within Manitoba, there is a tax on coal as well as regulations which preclude coal-fired electricity generation except to support emergency operations. Manitoba also has a Clean Energy Strategy which provides clear preference for the expanded use of low and non-emitting energy resources.

In Minnesota, utility resource plans must consider both the estimated regulatory costs of emissions – the cost of compliance with future regulations affecting electricity generators (see Section 9.2 in this Final Argument on carbon pricing), and externality costs of emissions - an estimate of all the economic damages associated with an increase in carbon emissions (see Section 19.2 in this Final Argument on externality costs of emissions). In addition to including these costs in utility resource plans, Mr. Eric Swanson noted in his testimony that Minnesota current state law essentially prohibits the construction of new nuclear facilities and a prohibition against the construction of any new base load coal- fired facilities unless and until there is either a state or federal hard cap, essentially, on greenhouse gas emissions (Tr. p. 1965, lines 1-9). Combined with federal EPA regulations, Mr. Swanson advises that in Minnesota "there's severe doubt as to the future of some of the current fleet as - -as well, which is why hydro has been so attractive to some of the US utilities" (Tr. p. 1965, lines 10-16).

Concerns over carbon regulation are driving utilities to advocate for carbon policies that are economically efficient and reduce policy uncertainty. As noted during the NFAT hearing[257] Great River Energy is publicly advocating for a MISO wide carbon fee to demonstrate regional compliance with the EPA's emerging GHG regulations for existing generating facilities. If the GRE proposal or one with a similar framework can gain traction across MISO stakeholders, states could enable MISO to incorporate a carbon fee into its operations.

[257] TR pg. 1390, lines 16-17

17.0 MH POSITION: CLIMATE CHANGE IMPACTS FOR MANITOBANS

The Intergovernmental Panel on Climate Change has determined that the warming of the climate system is unequivocal and it is extremely likely due to the observed increase in anthropogenic greenhouse gas concentrations. Changes in temperature and subsequent changes in precipitation and other environmental components have been observed throughout Manitba and are projected to ontinue to change into the future. Impact studies have been conducted globally, nationally and regionally to examine both the observed and projected impacts of climate change. These studies show that climate change impacts are occurring and are projected to continue into the future. MH Exhibit #191 contains a summary of observed and future projected impacts of climate change in Manitoba. This report reviews a sample of scientific literature on climate change impacts within Manitoba and many of these studies show that climate change is occurring and that the impacts are already being felt in many areas such as freshwater and terrestrial ecosystems. Furthermore, they show that impacts are projected to continue into the future. MH Exhibit #191-1 includes reference to the recently released US National Climate Assessment, which was prepared by the US Global Change Research Program, a scientific panel overseen by the US Government. This US climate assessment speaks to national and regional climate change impacts in the Midwest export region which may extend into Manitoba

Stakeholders in Manitoba are becoming more aware of the observed and projected impacts of climate change to their regions of interest. For example, as a result of these potential impacts of climate change to Lake Winnipeg, the Lake Winnipeg Foundation has developed and adopted the following position statement which guide their decision-making in regards to climate change:

> Global climate warming, from human-driven increases in atmospheric CO_2 with associated changes in rainfall, runoff, evaporation, ice duration, and temperatures in the Lake Winnipeg watershed, is impacting the Lake Winnipeg ecosystem. Extreme hydrological events, such as flooding and drought, are becoming more common and are detrimental to the lake's ecology and biodiversity. Increasing water temperatures are contributing to proliferation of toxic blue green algae and to invertebrate species changes which ultimately influence the Lake Winnipeg fish community. Lake Winnipeg Foundation supports policies and practices that reduce greenhouse gas emissions (February 1, 2012). (Lake Winnipeg Foundation, 2012) – MH Exhibit #191

17.1 MH Position: Climate Change Impacts Reasonably Addressed

Climate Change is a topic of interest for Manitoba Hydro and as such, strategies have been established to shape the organization's response to climate change which is described in NFAT, Appendix K. For the NFAT, the climate change sensitivity analysis undertaken by Manitoba Hydro is appropriate and reasonable given the state of the science, and its work is consistent with that of other major hydroelectric utilities. Expert witness, Dr. Rene Roy from the Ouranos Consortium which employs some of Canada's leading climate change researchers testified on March 12, 2014 that "[Manitoba Hydro] did the best they could with the information that was available[258]". Furthermore La Capra Associates (LCA) testified on April 9, 2014 and stated in MH/LCA-024 that they are not aware of any other generation developer, similar to Manitoba Hydro who have undertaken a more extensive analysis or advanced modeling of climate change impacts in a resource planning application[259].

17.2 Manitoba Hydro Sensitivity Analysis and Main Conclusions

Chapter 10, Section 10.2.2 of the NFAT Submission presents an analysis of the potential impacts of climate-changed streamflow on projections of average revenue under the All Gas development plan, the K22/Gas development plan and the Preferred Development Plan (K19/C25/750MW (WPS Sale & INV)). Manitoba Hydro employed state of the art Global Climate Model (GCM) runoff data to assess potential future changes to annual water availability in the Nelson-Churchill watershed under a changing climate. To account for the major source of uncertainty, a large ensemble of 109 simulations taken from 21 different GCMs driven by three future greenhouse gas emission scenarios was employed. The GCMs were used to create a broad range of future streamflow projections; which were input into the Simulation Program for Long-Term Analysis of Hydraulics model (SPLASH) to determine the long-term operations of Manitoba Hydro's system under the various Development Plans. In general, the projections of GCMs indicated that it is more likely there will be an increase in average annual streamflow as approximately 70% of projections show an increase in runoff. As the Manitoba Hydro system currently consists of predominately hydro-based generation, all plans will be affected by changes in streamflows driven by climate change. As a result there is a greater likelihood of an increase in average annual revenues than there is of decreased annual average revenues..

17.3 LCA and MNP Outstanding Criticisms and Lack of Expertise

LCA and MNP both commented on Manitoba Hydro's climate change sensitivity analysis[260] [261]. The main criticism from these Independent Expert Consultants (IECs) relates to Manitoba Hydro's consideration of changes to seasonally altered precipitation in the climate change sensitivity analysis and the absence of analysis on the probability and severity of future droughts as result of climate change and its related impact. Over the course of the hearings, these criticisms were addressed through Manitoba Hydro's rebuttal evidence[262], LCA/MH II-492 and expert witness testimony which demonstrated that the original criticisms were a function of the IECs incomplete understanding of the physical nature in which Manitoba Hydro operates its system.

MNP testified on April 4, 2014, that "In Hydro's rebuttal evidence[263] they provided greater clarity on the reason that they elected to conduct modeling on an annual average basis rather than on a seasonal basis. And we found that to be reasonable, acceptable[264]". It can therefore be concluded that MNP's criticism on Manitoba Hydro's consideration of seasonality is no longer a significant concern.

Through cross-examination, it was demonstrated that MNP's criticism on drought was based upon a literature review. It was revealed that MNP's "work on drought certainly isn't primary research. We reviewed documentation relating to climate change impacts which relied on other studies of the science of drought[265]". Careful examination of MNP's cited documents demonstrated that the strength of the literature reviewed by MNP was hindered by a lack of acceptable literature and failing to communicate key assumptions and limitations contained in the materials reviewed.

MNP's commentary on drought primarily relied upon work by Stern (2006)[266] which relied upon Burke et al. (2006)[267] for future drought analysis[268] [269]. Burke et al. (2006) assessed shorter-term meteorological drought and the authors acknowledges that their method

[269] April 4, 2014 Transcript page 5443, lines 12-13.

"...should not be used as a measure of hydrological drought[270]". On April 4, MNP concurred that the Burke paper was based on meteorological drought[271]. As such, Burke's research does not directly apply to Manitoba Hydro's system, where multi-year hydrological drought is of primary interest. Furthermore, Burke et al. (2006) recognizes the limitations of their studies which utilizes a single climate model, and states that: "there is a need for these results to be corroborated by other climate models[272]. Therefore, since uncertainty was not adequately considered, the results in these studies cannot be taken with absolute confidence.

It should also be noted that "No Nelson-Churchill River Basin studies were used[273]" when MNP conducted their assessment and instead, "MNP has made inference based on reported results of global modeling and impacts on northern watersheds[274]". MNP's inferences originate from Nordic/Baltic region report[275] which includes areas considerably different in size, climatology and geography, when compared to the Nelson-Churchill watershed and therefore the Nordic/Baltic region report does not constitute a reasonable base on which to make inferences.

On April, 9, 2014, LCA testified that they do not have any expertise in climate change modeling or hydroclimatology[276] and their review was simply reporting on the limitations that Manitoba Hydro had already identified[277 278].

17.4 Ouranos Support

In light of these criticisms, Manitoba Hydro sought the opinion of the Ouranos Consortium on Regional Climatology and Adaption to Climate Change ("Ouranos)", regarding Manitoba Hydro's use of the scientific data, including future climate change projections of extreme events such as prolonged hydrologic drought[279]. Ouranos was created in 2001 as a joint initiative of the Quebec Government, Hydro-Quebec and Environment Canada. The consortium brings together 450 scientists and professionals that have considerable experience in climate change impacts and adaptation including a focus on energy supply and water

resources. Ouranos has developed an internationally recognized expertise, participates in international research projects and regularly publishes in scientific journals. Ouranos conducts integrated research projects that combine the development of regional climate change projections, the assessment of physical and human impacts related to climate change and adequate measures to prepare them and different stakeholders in adaptation[280].

In Ouranos' written testimony[281] and in their oral testimony given by expert witness Dr. Rene Roy on March 12, 2014, Ouranos stated that they do not agree with the concerns raised by the IECs[282]. Research is still ongoing and there is currently no power utility accepted standard methodology to quantify climate change impacts on extreme events (i.e. floods and droughts)[283] [284] [285]. As a result of the state of the science, there is low confidence in future projections of drought as it relates to climate change in the Nelson-Churchill watershed and as such the information is not available to undertake a quantitative assessment based on a scientific consensus as suggested by MNP. In the absence of clear information on future droughts, it is best to use historical records. Consequently Manitoba Hydro has quantitatively addressed drought on the historical record of water flows in NFAT Chapter 10, Section 10.2.1 and has qualitatively assessed the impacts of a drought worse than the drought of record in NFAT Chapter 10, Section 10.3.3. This was supported by Ouranos "if you need clues on the future droughts is to look in the back and analyze your historical information[286]". Ouranos went on to state in their oral testimony "... considering the worst drought in their historical records was by far the best approach they could have used at this time[287]" and with "99 years records of flow, [MH has] lot of years behind that [MH] can rely on[288]". In Ouranos written testimony they went on to state that ".... maintaining historical droughts from the meaningful LTFD records presents a good way to compensate the limitations of the delta approach with respect to representing drought in future climate scenarios[289]". Furthermore, they described a hydropower generating station being planned in 2008 by Hydro Quebec where they "haven't been using climate change information[290]" and that if they did it again they "would use an approach such as Manitoba Hydro[291]".

17.5 Conclusion on Climate Change

Studies show that climate change is occurring and that the impacts in Manitoba are already being felt in many areas such as freshwater and terrestrial ecosystems. Furthermore, they show that impacts are projected to continue into the future. As described in NFAT Appendix K, Manitoba Hydro has demonstrated that the Corporation has a very comprehensive climate change impact study program and is "ahead of the curve" in terms of being well informed about changes in the climate sciences field. At this time, given the current state of the science, Manitoba Hydro has done a reasonable climate change sensitivity analysis and the results show that the PDP continues to be viable under climate change projections, as do the Plans with Keeyask and the 750 MW Interconnection.

17.6 The Preferred Development Plan Delivers the Greatest Greenhouse Gas Reductions

Manitoba Hydro's PDP results in the least GHG emissions within Manitoba and the greatest displacement of GHG emissions outside of the province. To a lesser degree, development plans featuring Keeyask (without Conawapa) and the 750 MW interconnection also deliver significant emission reductions, while plans that rely on natural gas generation result in the greatest emissions within Manitoba and the least displacement of GHG emissions outside of Manitoba.

The physical realities of climate change require a development plan which reduces GHG emissions globally and is well aligned with a carbon constrained future. The Intergovernmental Panel on Climate Change (IPCC) has determined that climate warming is unequivocal, human influence on the climate system is clear, and continued emissions of GHGs will cause further warming and changes in all components of the climate system. The IPCC stresses that limiting climate change will require substantial and sustained GHG emission reductions.[292]

The Pembina Institute's life cycle assessment figure below (MH Exhibit #85, page 111) demonstrates that the Keeyask and Conawapa projects have the lowest GHG emissions per unit of generation compared to any other resource option, including wind. "A comparably size high efficiency combined cycle natural gas turbine would have more direct GHG emissions in its first half year of operation than the full life cycle GHG emissions of the

[292] CAC/MH I-231a.

Keeyask G.S. over its 100 year life".[293]

The various development plans outlined by Manitoba Hydro affect GHG emissions both within and outside Manitoba, resulting in different climate change impacts. Plans which rely on natural gas generation increase local GHG emission and correspondingly reduce the potential for GHG displacement outside of the province. As MNP indicates, "The most significant long-term impacts are those direct -- are those associated with the direct impacts of climate change, which may be further exacerbated by GHGs and air pollutants in the short term that would be associated with alternative plan that are reliant on gas generation"[294]. The PDP offers the greatest opportunity to displace fossil fuel-fired electricity and associated GHG emissions in jurisdictions outside of Manitoba through exports of lower emitting hydroelectricity (Table 1 – Response to MNP Undertaking 98).[295]

As discussed in the previous climate change Section 17.5, studies show that climate change is occurring and that the impacts in Manitoba are already being felt in many areas such as freshwater and terrestrial ecosystems and that these impacts are projected to continue into the future. Emission reductions both inside and beyond the border of Manitoba will contribute to mitigating Manitoba climate change impacts. Science continues to demonstrate the increasing urgency to reduce GHG emissions associated with human induced climate change. Development plans that maximize hydropower production in association with a 750 MW interconnection deliver the greatest emission reductions. Furthermore, emerging policies are expected to increasingly constrain high emitting resources and reward lower emitting resources. The PDP which includes Keeyask and Conawapa hydroelectric generating stations will deliver the greatest GHG emission reduction benefits in a carbon constrained future, while those with Keeyask and the 750 MW Interconnection the second largest reductions.

18.0 GREENHOUSE GAS EXTERNALITIES FAVOUR THE PREFERRED DEVELOPMENT PLAN

The PDP results in the lowest greenhouse gas externalities within Manitoba and the greatest displacement of greenhouse gas externalities outside of the province. The remaining Keeyask and 750 MW interconnection plans have the second lowest greenhouse gas externalities in Manitoba and the second highest displacement outside the Province.

The Manitoba Sustainable Development Act requires the integration of environmental and economic decisions. This involves ensuring that no costs associated with a decision or action, including externalized costs, are left unaccounted for. Further the principles require global responsibility. Manitobans should think globally when acting locally, recognizing that there is economic, ecological and social interdependence among provinces and nations. [297]

The Green Action Centre highlighted the externality issue identified in *The Economics of Climate Change: The Stern Review* authored in 2007:

> "Climate change is a result of the greatest market failure the world has seen. The evidence on the seriousness of the risks from inaction or delayed action is now overwhelming. The problem of climate change involves a fundamental failure of markets. Those who damage others by emitting greenhouse gases generally do not pay."[298]

Manitoba Hydro's economic analysis dealt with expected carbon price cost however these only captured a modest portion of the total externality cost of GHG emissions. MH Exhibit #185 demonstrates that the range of climate change policies under discussion would deliver only a modest portion of the total social and environmental damages and risks associated with climate change. To further account for environmental externalities, the multiple accounts analysis acknowledged that "*Recent estimates of the social cost of GHG emissions are much higher than the assumed carbon charge*"[299]. Within the multiple account analysis, the social cost of carbon was thus used to represent the environmental and social damage costs and risks of climate change due to Manitoba thermal generation-related GHG emissions. As part of the direct evidence, the reduced Manitoba GHG externality cost associated with the PDP relative to the all gas plan was estimated to be $320 Million (6%

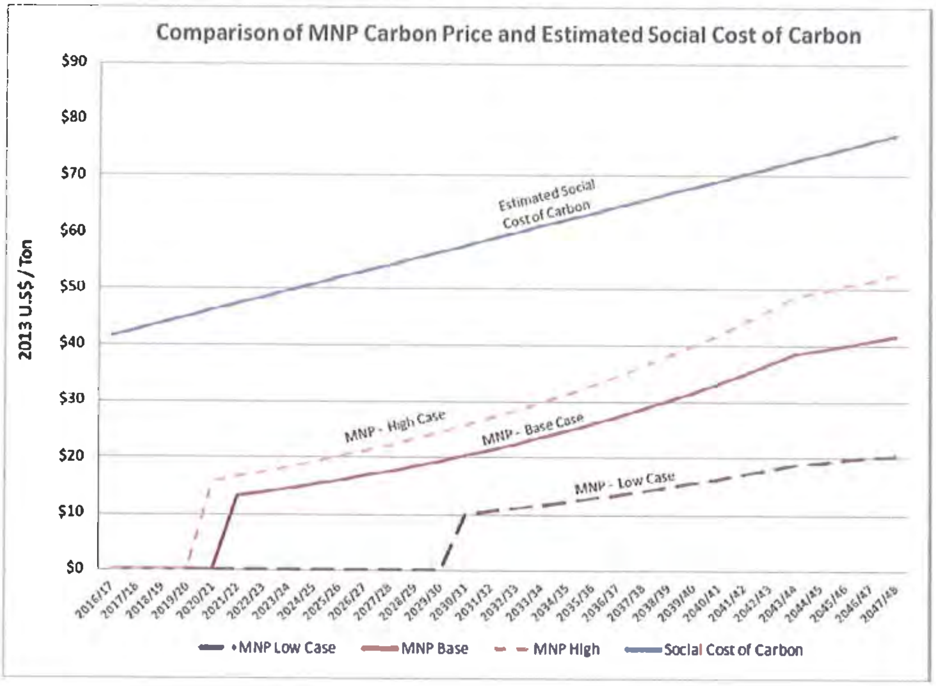
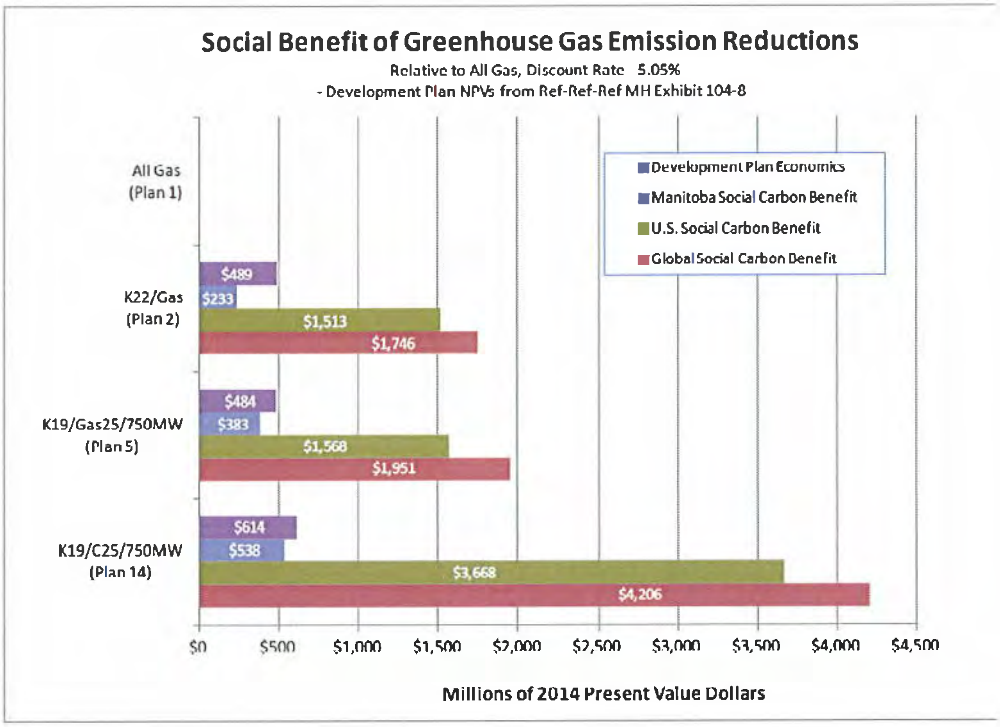
discount rate, present value $2014)[300]. This value from the multiple accounts analysis nets out internalized costs such as the Manitoba coal tax and an estimate of future carbon charge payments.



MH Exhibit 185 – Figure 2

300 MH-129-6, Page 8.



MH Exhibit # 185 – Figure 1

The global GHG externality was not quantified as part of the multiple accounts analysis. However, in response to a request from the Green Action Centre, Manitoba Hydro prepared additional analysis which determined the approximate externality benefit of GHG emission reductions from three perspectives: Manitoba, U.S. and the combined global perspective. The PDP offers the greatest global externality benefit from the reduction of GHG emissions – in excess of $4 Billion (present value $2014).[301] This results directly from the PDP having both the lowest GHG emissions within the province and the greatest displacement potential of emissions outside of the province relative to the all gas plan. The Keeyask, Gas 25, 750 MW plan yields approximately a $2 Billion (present value $2014) global externality benefit.

19.0 MULTIPLE ACCOUNTS SOCIETAL BENEFIT COST ANALYSIS

19.1 Introduction

Chapter 13 of the NFAT Application presented the results of a multiple account benefit-cost analysis (MABCA) of the preferred development plan compared to alternatives with and without the Keeyask project; and with and without a new US interconnection and new export sales agreements. The MABCA extended the assessment of alternatives from a Manitoba Hydro perspective to a broad Provincial social perspective and was specifically intended to assist the Panel in addressing the question of overall socio-economic benefit as called for in the NFAT Terms of Reference.

Benefit-cost analysis is widely recognized as a logical, consistent method of evaluating alternative projects and policies from a broad social or societal perspective. MABCA is an extension of traditional benefit-cost analysis that explicitly recognizes not all consequences can reliably be monetized. It highlights the advantages, disadvantages and trade-offs among the alternatives – not simply the overall bottom line. In terms of conducting the analysis, Manitoba Hydro ensured that it was thorough and went as far as hiring a recognized expert in the field of benefit-cost analysis; Dr. Marv Shaffer. Dr. Shaffer developed the MABCA framework for the evaluation of major crown corporation policies and projects in British Columbia and is a recognized expert in benefit-cost analysis. He teaches a course in benefit-cost analysis in the Public Policy Program at Simon Fraser University and has written a highly regarded textbook on the multiple account approach. No other expert who appeared before this Board has the same type or level of expertise in benefit cost analysis as Dr. Shaffer.

19.2 Findings

The findings of the MABCA are clear and are important in the integrated comparisons of development plans. These findings can be summarized as follows:

1. There are greater net benefits for Manitobans in developing the Keeyask project than relying on gas-fired generation when needed to meet growing load;
2. There are greater net benefits in developing Keeyask with the 750 MW interconnection and export sales opportunity than without;

3. The advantage of the development of Keeyask with the 750 MW interconnection and sales agreements increases when moving from a Manitoba Hydro perspective to a broad Provincial social perspective;
4. The monetized net benefits for Manitobans are greatest for the Preferred Development Plan, though generally similar to other plans that include Keeyask and the 750 MW interconnection and sales agreements.

These findings were based on the initial analysis performed and were confirmed in the updated capital cost sensitivity analyses which included Manitoba Hydro's latest detailed project estimates of higher capital costs and the elimination of the WPS investment (MH Exhibit #166). The MABCA also examined the GHG externalities implications which are dealt with later on in Section 18.0 – Greenhouse Gas Externalities Favour the Preferred Development Plan.

It is important to note that the monetized values in the MABCA were based on a number of purposely conservative assumptions – assumptions intended not to overstate the benefits of the Preferred Development Plan. The monetized results do not include the estimated value of the additional reliability that the preferred development plan offers and it does not recognize all of the potential government revenue benefits (for example the debt guarantee fee, sales taxes embedded within the project expenditures or the income taxes paid by in-migrants). The monetized values are also based on conservative assumptions with respect to the employment benefits for Manitobans and do not include the potential long term bequest value the hydro projects can offer. In terms of the social cost of carbon, a conservative approach was taken in two respects: the relatively low values for the benefits of lower GHG emissions in Manitoba, and not including any of the benefits of GHG reductions outside Manitoba even though Manitobans will share in that benefit as well. (Tr. p. 4163-4165 and Tr. p. 4233-4234).

19.2.1 Validity of the Evaluation Methodology

Dr. Gibson raised an issue regarding the potential for non-monetized consequences in an MABCA being 'marginalized' (Tr. pg. 9153-9154). That, however, misses the very point of the MABCA. The intent of the analysis is to identify the full range of consequences, assess their significance and highlight both the monetized and non-monetized trade-offs. As indicated by Dr. Shaffer, the important question to ask in this case is whether there is a reason to believe that the non-monetized consequences of the PDP are in the magnitude of a billion dollars (which is the difference between the monetized net benefit of the PDP versus All Gas shown in the updated analysis under MH Exhibit #166). (Tr. pg. 3999-4000).

MABCA enables reasoned, well-considered judgments to be made within the well-established, logical and consistent framework of benefit-cost analysis. Dr. Shaffer explained very clearly how that trade-off analysis assists in making reasoned, well-considered judgments about the relative merits of different plans. (Tr. pg. 3998-4000). That cannot be said about the application of an ad hoc set of criteria that one individual or group might think is appropriate.

19.2.2 Need for Fully Completed Environmental Assessments

Mr. Hendriks suggested that fully completed environmental assessments are required before any NFAT conclusions can be reached based on MABCA or presumably any other evaluation methodology (MMF Ex. 26, p.15). That, however, is neither practical nor true. Just as with the staged assessment and subsequent refinement of engineering, market and other information critically important to the evaluation of alternatives, reasoned judgments can be made with quite extensive and well-considered, even if not finalized, environmental and social impact assessments.

While Mr. Hendriks may wish to dismiss the important choices people make (Tr. pg. 9154 and MH/MMF Camerado Response to IR -016), the fact is that the willing participation of a majority of the Keeyask First Nation partners indicate the assessment that these First Nation partners made and the conclusion they reached – that it is better to proceed with the Keeyask project than not. The residual adverse effects will be sufficiently minimized or offset by the benefits the project offers. In economic terms, that means that the impacts in the view of those most directly affected by that project have been addressed in the design, implementation and partnership plans.

With respect to environmental and social impacts of Keeyask and other projects that may affect others, the MABCA explicitly recognizes there may be non-monetized adverse (as well as positive) effects. However, as stated in Chapter 13, p.67, Manitoba Hydro's assessments suggest there would not be major residual effects or trade-offs "given the extensive monitoring, mitigation and other measures that are planned, **but this will be addressed in detail in the environmental hearings the projects require"** (emphasis added).

> Conclusions can be reached and judgments made providing the rationale for next steps, including further investment in detailed project-specific planning, design, and hearing processes.

19.2.3 Consistency in the Use of the 6% Real Discount Rate

An issue was raised about whether the 6% rate was consistently used in the MABCA. Specifically, it was suggested that the 6% rate was only used up to 2047, but a rate of 5.05% was used after 2047 (Tr. p. 8537).

The monetized present values in the MABCA were calculated with a 6% real discount rate. As explained in Chapter 13, p.5 (see especially footnote 7), this was based on recent research into the estimated weighted average opportunity cost of capital. Also, it was a rate considered appropriate for an analysis from a provincial perspective where more of the capital would come from outside the jurisdiction (as opposed to displacing other capital investment within it).

While there is considerable debate in the economics profession and within government agencies as to the appropriate discount rate to use in benefit-cost analysis, the 6% rate is well within the norm and many would argue that it is higher than what is appropriate, especially for projects with long term consequences.

As Dr. Shaffer explained, that suggestion that the 6% rate was not consistently used in the analysis fails to recognize that the present value calculations in the MABCA were only done for estimated values over the 2014-2047 planning period. (Tr. pg. 4236-7). As is standard and necessary in discounted cash flow analyses with assets having useful project lives beyond the end of the planning period, residual asset values in the final year of the analysis (in this case 2047) was estimated and the differences among the plans taken into account. The residual asset values that the MABCA used were the 2047 present values that Manitoba Hydro calculated with its post 2047 projections and somewhat lower discount rate.

One could argue that the MABCA could have used lower residual asset values, ones for example that Manitoba Hydro would have calculated had it applied a higher discount rate to the long term (post 2047) projections. The effect of that would be to give less weight to the long term benefits of very long life assets.

If anything, however, the stronger argument is that the MABCA should have used higher residual asset values, ones that were based on lower intergenerational discount rates. That is what many economists now argue should be done to give proper weight to the very long term effects different projects may have – in this case to fully recognize the very significant bequest value the assets offer future generations. (See Chapter 13, page.62-4). Had that been done it would have increased the monetized advantage of the Preferred Development Plan.

19.2.4 Inconsistent Discount Rate, and Use of Declining Discount Rate

In CAC final argument, Exhibit 91-1, Mr. Harper argues that the MABCA uses different discount rates pre and post 2047. As explained in the previous point, this fails to recognize that the MABCA does not in itself discount beyond 2047. The market valuation account uses MH estimates of cash flows and residual values. With respect to the latter, the MABCA did not adjust the residual value MH calculated with MH's own discount rate.

The only reason to adjust the MH-estimated residual values in the MABCA would be if they didn't reflect the residual value of the assets from a broader social as opposed to MH perspective. But as Dr Shaffer explained in his evidence and under cross examination, if any adjustment should be made it should be to increase the residual values (based on a lower the long term intergenerational discount rate). There is a large and growing body of literature suggesting inter-generational discount rates should be lower than the standard weighted average opportunity cost of capital used over an intra-generational planning period.

Mr. Harper asserts that there is no agreement on the use of declining discount rates. First it should be noted that the **MABCA did not apply a declining discount rate to calculate a social bequest value of the residual assets**, as many would recommend. It simply noted there may be such a value. And second, whatever uncertainty there may be with respect to declining discount rates, Mr. Harper would find little support for arguing that a higher rate than MH used to calculate residual values should be used to determine their worth from a social perspective. That is what he seems to want – to give even less weight to the very valuable hydro assets the preferred and other hydro plans offer. Had Manitobans in the past done what Mr. Harper seems to recommend Manitoba Hydro would never have developed the existing hydro assets which have and continue to serve Manitoba ratepayers so well.

19.2.5 Impact of Higher Levels of DSM

As Mr. Harper notes higher levels of DSM were not part of the reference case analyzed in the MABCA (CAC Final Argument Exhibit #91-1, page 47). However, the resource analyses that Manitoba Hydro provided during the hearing indicate how the market valuation of the plans would be affected, and that directionally indicates how the MABCA results would be affected. The key point is that it wouldn't alter the main conclusions of the MABCA – that the pathways with Keeyask and the new 750 MW interconnection are better than the alternatives.

A further consideration is that the market account evaluations of the plans which include Keeyask and 750 MW, with updated capital costs, yield approximately the same level of NPV benefits regardless of the level of DSM.

19.2.6 Rate Impacts

Mr. Harper asserts that it would have been better to calculate an NPV of the rate impacts in the customer account in the MABCA (CAC final argument, Exhibit #91-1, Pg. 49-51). This, he asserts, would better capture the overall effect on ratepayers.

First, Mr. Harper does not recognize the express purpose of this part of the customer account in the MABCA. It was to address the distributional issue – how rates would be affected in the short to medium versus long run. That is something an overall present value calculation would not do.

Second, Mr. Harper fails to recognize that the market valuation account effectively does what he is calling for – determine the present value costs of the different plans that customers will ultimately have to pay for. It would be a mistake (and is certainly not done elsewhere) to calculate a present value of estimated rate impacts in addition to a present value of net utility expenditures. The present value of rate impacts would double-count what is already incorporated in the market valuation account. And it would fail to include any provision for the residual value of assets at the end of the rate forecast period. In the context of long lived hydro assets that would be a serious error and provide very misleading results.

Mr. Harper goes on to discuss what discount rate he would recommend for calculating the present value impact on ratepayers. He says a rate between 3% and 8% should be used. The MABCA used a rate of 6%, well within the range Mr. Harper recommends (indeed arguably conservatively so). What he is calling for has been done, and where it appropriately should be done – in the calculation of present value MH expenditures less export revenues – the net costs customers will have to pay for.

19.2.7 Trade-Offs In MABCA Results

Mr. Harper notes that the MABCA results point to trade-offs between the market valuation and government accounts (CAC final argument, Exhibit #91-1, Pg. 51-52). That is correct. However, from a Manitoba point of view it is the sum of these accounts that matters most. That will indicate how Manitobans as ratepayers and taxpayers are best served. As for whether government should take steps to change the distribution of benefits – whether there should be, for example, lower taxes than otherwise or lower rates – is a policy issue that only government can address.

19.2.8 Consideration of Aboriginal Consultation Costs from Government

In its Final Argument, MMF (Tr. p. 11188-9) raises an issue that the government costs for aboriginal consultation (Constitution, Section 35 consultation) have not been included or broken down in the multiple account evaluation, in the government account. In cross-examination (Tr. p. 4004) Dr. Shaffer clarified that these costs are either sunk (particularly with respect to the Keeyask project); common (at least for those projects that are included in the different plans); or included in the costs that Manitoba Hydro estimates it would incur for the other projects, including the transmission lines MMF is specifically concerned about. The key point is that it is Manitoba Hydro's best assessment that there will be no significant differences in government costs between the different plans that have not already been taken into account in the analysis.

19.3 Conclusions about MABCA

Typlan, the independent expert consultant to the Public Utilities Board who reviewed the evaluation in Chapter 13, recognized the MABCA methodology as standard and appropriate. (Tr. p. 6999; Tr. p. 7021-22; and Tr. p. 7024). CAC Consultant, Dr. Gibson, also recognized it as having some very clear advantages, including that it is an extension from relatively conventional economic analysis practice, the methodology uses available data and the ability for the methodology to capture quantified comparisons on some important considerations. (Tr. p. 9153).

In short, the findings of the MABCA are solid and robust. Manitoba Hydro conducted the analysis and placed the results before this Board in an open and transparent manner in order for them to be tested and challenged. It is important to note that there was very limited cross examination on the MABCA, there were no specific challenges to the findings of the MABCA and no evidence presented to the Panel which contradicts those results.

20.0 ECONOMIC IMPACT ANALYSIS

Economic Impact Analysis is one piece of the overall study of the impact that development plans would have on the Province of Manitoba. This analysis provides an estimate of the gross total employment impacts, labour income of a project, tax revenue impacts and of the total Gross Domestic Product. The magnitude of the impacts depends upon the amount of material, equipment and labour required for the project, and their likely origin of supply. The result of the economic impact analysis indicates that the Preferred Development Plan will result in nearly seven times more direct and indirect employment benefits as compared to the All Gas Plan (Appendix 2.3 – Economic Impact Assessment). The plans with Keeyask and the 750 MW Interconnection, but without Conawapa would have approximately half the impact of the Preferred Development Plan. While there was some criticism of Manitoba Hydro's analysis, the independent expert retained by the Public Utilities Board stated that, "...the results confirm that the PDP creates the greatest economic impacts..." (Typlan, 2014, iii). Moreover, if Manitoba Hydro was to reassess the Economic Impacts using the model suggested by Typlan, Typlan concluded that "...the benefits to Manitobans is greater than what was reported."(Ibid.)

20.1 Preferred Development Plan

The Preferred Development Plan (PDP) is expected to have significant, positive economic impacts on the Province of Manitoba with the major economic impact being from construction: *"Overall the PDP exhibits the greatest socio-economic benefits to the people of Manitoba, northern communities and First Nations compared to other plans based on the reference plans evaluated."(Typlan, 2014, vii)* As detailed in Appendix 2.3, these impacts are as follows:

a) Total provincial direct and indirect employment impacts are estimated at 19,246 person-years;
b) The total provincial labour income impact is estimated at $1,480,224 million;
c) Total provincial Gross Domestic Impact is estimated at $1,944,640 million;
d) Provincial and local tax revenues generated in Manitoba are estimated at $581,845 million.

During the operational phase, it is estimated that the PDP will generate 295 person years of direct, indirect and induced employment, $12,641 million of labour income, and $2,133 million in provincial and local tax revenues annually.

The total Manitoba direct employment impact for the PDP project is 10,524 person years, compared to 1,491 for All Gas. This represents a difference of about 9,033 person years. The total direct, indirect and induced employment impact for PDP is 19,246 person years, compared to 2,829 person years for All Gas. This represents a difference of 16,417 person years.

Economic Impact Summary for Preferred Development Plan

	Construction	O&M (Average Annual)
Employment (Direct, indirect and induced) in Person Years	19,246	295
Provincial and Local Taxes ($million)	$581,845	$2,133
Provincial GDP ($Million)	$1,944,640	$14,697
Labour Income (SMillion)	$1,480,224	$12,641

Preferred Development Plan Employment Versus All Gas Plan Employment

Impact	Construction	O&M (Average Annual)
PDP Employment (Direct, indirect and induced) in Person Years	19,246	295
All Gas Plan Employment (Direct, Indirect and induced) in Person Years	2,829	579
Difference: PDP – All Gas	16,417	(284)

20.2 Approach and Criticism of Manitoba Hydro

Economic impacts were estimated using the Manitoba Bureau of Statistics Input-Output (I-O) Model that can trace the demand for one good to demands for all goods in the economy (Appendix 2.3). The model is based on statistical information about the flow of goods and services among various sectors of Manitoba's economy. In effect, it allows one to trace the demands placed on one industry resulting from increased activity in another. Thus the model provides estimates of direct, indirect, and induced impacts of the proposed project. These estimates indicate gross impacts and not incremental or net benefits impacts. Typlan utilized a different model to analyze the impacts and concluded that potential benefits to Manitoba may be understated. Despite this, Mr. Tyson agreed that the use of a provincial I-O model, as opposed to a national-level model, is consistent with standard practice in other utilities across Canada (Tr. Pg. 7160, lines 13-17).

Mr. Tyson indicated that the treatment of many purchases as leakages, as presented by Manitoba Hydro, may have underestimated the impact of the project on Manitoba, while overstating the impact on Canada (PUB/TyPlan -006a; Tr. p. 6970). Manitoba Hydro's economic impact analysis approach is based on project-specific expenditures or data, and requires breaking down overall expenditures by appropriate goods and services (and by jurisdiction in which the expenditure will take place, i.e., Manitoba, Rest of Canada and Foreign). The non-Manitoba sourced expenditures represent leakage or loss to local economy. This project specific analysis is based on expert opinion and experience from past projects, as well as knowledge of changes to the structure and composition of Manitoba's economy. On cross-examination, Mr. Tyson confirmed that, "without a full understanding of either the Manitoba economy or how it functions and an understanding of ongoing contractual arrangements between Hydro and its service providers, it is difficult to ascertain the extent of leakages and how margins are treated" (Tr. Pg. 6968).

21.0 PATHWAYS AND OPTIONALITY

21.1 Uncertainty and the Value of Optionality

In its planning and the NFAT submissions, Manitoba Hydro proactively recognizes that the future is uncertain and that optionality – flexibility, learning and adapting – is critically important and assists in a plan being more robust (Wojczynski, Tr. p.81-87.) Some argue that Manitoba Hydro should have addressed optionality more extensively (Bowman filing, p. 3-6). Manitoba Hydro understands that more analysis is always possible, but has addressed optionality both qualitatively (Manitoba Hydro NFAT Filing, Chapter 14) and quantitatively (PUB/MH 1-279). As Dr. Borison, an expert in this area, pointed out in his report:

> "Manitoba Hydro put considerable emphasis…on flexible pathways in addition to fixed plans, and on recognition that events going forward should be monitored over time, updated analysis conducted and adjustments made." (Schedule 3 of Rebuttal Evidence of Manitoba Hydro, MH Exhibit #85, p. 10)

Optionality is captured more fully in the NFAT analysis than is typically the case, even for large investments.

Mr. Bowman agrees that optionality and decisions unfolding over time are key to making decisions about the development plans and that "it's advisable to decide the things you have to decide and then set out the processes to make the other decisions" (Tr. p 10040, lines 15-24).

As suggested in the Introduction to Final Argument, the decisions required up front on proceeding with Keeyask and the 750 MW Interconnection need to consider the uncertainties in the future and the range of future possible decisions associated with each pathway. This includes being aware of opportunities that are lost if these developments are deferred or not pursued. Once the initial path is selected, the decisions that can be made later should be left to a time when the decision is required, at which time more updated information will be available. The most critical of such future decisions relates to the timing and commitment of Conawapa.

21.2 Conawapa Protection, Commitment and Optionality

The Preferred Development Plan was defined in the August 2013 NFAT Submission to include Conawapa with an earliest in-service date (ISD) of 2026.

The Submission specifically recognized that conditions would be continuously monitored to determine if the in-service date for Conawapa should be deferred and if continued protection of Conawapa was warranted (Executive Summary, Pages 1-2). The Submission (Chapter 14, pages 48-49) further goes on to discuss benefits of the optionality associated with Conawapa which allows Manitoba Hydro to mitigate the downside risk while preserving the upside potential of this project.

While there has been a reduction in the net economic benefits resulting from plans that include Conawapa, Manitoba Hydro has decided to continue to include Conawapa as a possibility in the Preferred Development Plan and its associated pathways (Tr. p. 3717, lines 10-19).

Conawapa Schedule and Protection Costs

Manitoba Hydro is currently protecting Conawapa for an ISD of 2026 which would require a construction commitment by early 2018. As depicted in the Pathways Optionality diagram in MH Exhibit #192, Manitoba Hydro will monitor annually the benefits and cost of protecting Conawapa and decide whether to continue protecting for the target ISD, defer the date or stop protecting Conawapa at all. As discussed in Section 17.2, protecting an early date for Conawapa is still relevant, even with the updated analysis, because (a) it fits with the timing of specific actual and potential new export arrangements that would have long term benefits for Manitoba Hydro and its ratepayers and (b) it preserves the value of the investment already made in Conawapa.

The decisions regarding the continued protection of Conawapa will be affected by factors such as progress on negotiations on additional long term export contracts, export prices, capital cost estimates, interest rates, load forecast and DSM plans.

The Conawapa activities for the current fiscal year 2014/15 are already underway and include engineering, environmental studies, licensing and aboriginal discussions and are estimated to be in the order of $50 Million (Tr. p. 3718). If a decision were made in the summer of 2014 not to pursue construction of Conawapa, much of the work planned for the current fiscal year would have been undertaken or committed, and Manitoba Hydro would incur additional costs to wind-down contracts and studies already underway (Tr. p. 3722-3723). If Conawapa were halted and then restarted at some later date, additional work, cost and time would be required to restart the processes. As Mr. Wojczynski testified, if such a halt period were five years or more, most of the environmental studies which have been undertaken would need to be repeated, the community processes repeated and some engineering reworked (Tr. p. 3724-3725).

Activities and costs currently planned for Conawapa for subsequent years are outlined in Manitoba Hydro's response to PUB/MH I-238c and were also discussed by Mr. Wojczynski during the hearing (Tr. p. 3723-3725). These activities include completing community consultations, concluding development agreements with certain communities, obtaining environmental licenses and other approvals, undertaking detailed engineering and arranging construction procurement so that construction can start January 2018 for a 2026 ISD. These same costs would be similar but spread out should the protection ISD be deferred one or a few years but less than five.

As Mr. Wojczynski indicated, if a decision is made to continue protecting Conawapa for an early date and subsequently factors begin to indicate that Conawapa may not be proceeded with, it is likely that only a portion of the expenditures would be incurred as Manitoba Hydro would slow down its spending on protection activities as these factors become more certain. The Conawapa business case will be closely monitored on an ongoing basis and the work activities adjusted or terminated as appropriate.

As noted earlier, Manitoba Hydro is currently planning to protect Conawapa until 2018 or until such earlier time as new information indicates that the project should be abandoned. The 2018 date for a commitment decision arose initially from the ISD of 2026 that was part of the original Preferred Development plan. As a result of the increased levels of DSM that now appear possible, the optimum ISD for Conawapa will be reviewed by Manitoba Hydro. By summer of 2015, power resource evaluations will have further assessed the appropriate ISD to be protected for Conawapa. MH has testified that 2026 may not be the most likely date that will continue to be protected (Tr. p. 3720, lines 4-12). Assuming DSM level 2 and assuming Plan 6 (Keeyask 2019, MP 250 Sale, new interconnection), Conawapa could be deferred well beyond 2026 if it is required only for Manitoba load. With the 2013 load forecast that date could be 2040 assuming the incremental pipeline load does not occur (MH Exhibit #171) and a number of years earlier than that with the pipeline load.

There are a number of long term export contracts under negotiation which would require an earlier Conawapa ISD. The Wisconsin Public Service (WPS) 308 MW contract would require Conawapa no later than 2030. Conawapa would need to be earlier than this if the Northern States Power (NSP), Great River Energy (GRE), SaskPower or other long term contracts were to proceed. As Mr. Wojczynski indicated (Tr. p. 3707, lines 6-21) it is likely that having only a portion of the potential new export contracts would be sufficient to trigger such earlier dates for Conawapa.

22.0 RECOMMENDATIONS AND JUSTIFICATION

22.1 Keeyask and 750 MW Interconnection Recommendation and Justification

This section addresses the recommendation as to whether the plan to develop Keeyask Generation Station for a 2019 ISD and a 750 MW Interconnection for a 2020 ISD is needed and in the best long-term interest of Manitoba and Manitobans when compared to other options and alternatives. Section 17.2 addresses the future development of Conawapa.

"Need" is interpreted by Manitoba Hydro to mean a requirement for new electrical power resources to ensure that Manitoba domestic firm load along with committed firm exports can be supplied with adequate reliability and certainty (MIPUG/MH I-001a).

There is inherent uncertainty as to the specific future date when new resources are required due to uncertainty in load growth and uncertainty in resources, whether they are supply-side or demand side. As discussed in Final Argument Section 5.4, application of the Generation Planning Criteria results in a need date which can vary depending on which load forecast is assumed, the amount of DSM targeted and achieved, and the assumptions as to supply.

Plans with Keeyask advanced to 2019 and a new interconnection simultaneously provide for a range of potential domestic load need dates and provide a wide range of benefits to electricity consumers and Manitobans generally.

The most current information indicates that plans with Keeyask in 2019 and the Interconnection in 2020 are more economic from the Manitoba Hydro perspective than viable plans without Keeyask and the Interconnection. This information also indicates that advancing Keeyask to 2019 and developing the Interconnection is more economic than developing Keeyask at a later date without the Interconnection.

Plans with Keeyask 2019 and the Interconnection are also favourable to ratepayers as they provide lower rates over the long term relative to plans without Keeyask and the Interconnection or Keeyask at a later date without the Interconnection; provide benefits to the provincial government through financial transfers; provide reliability and energy security benefits to Manitoba domestic electricity consumers; provide a large reduction in GHG emission; and overall provide the most socio-economic benefits to Manitobans, especially Northern and aboriginal communities.

22.1.1 Need for the Keeyask / Interconnection Plan

The NFAT process has identified a range of need dates, depending upon assumptions included. Need dates range from 2023 to 2031, as described in Section 5.4 of this Final Argument. The evidence has demonstrated that Level 2 DSM represents the economic level of DSM appropriate for Manitoba Hydro to adopt. Assuming the 2013 load forecast along with the pipeline load and combined with DSM level 2, the projected Keeyask ISD for domestic need would be 2024. (MH Ex 104-3 and Tr. p. 9853 –9854). This date could be later or earlier due to adjustments in the load forecast, the DSM program and the supply situation (Final Argument, Section 5.4).

Advancing Keeyask by five years to 2019 would allow associated export sales and the new interconnection to proceed. Aside from the economic and other benefits, such a plan would help ensure that the uncertain needs of domestic customers can be met. As explained in Manitoba Hydro's oral evidence, higher than anticipated load growth is a greater challenge to deal with than lower load growth. Plans with Keeyask and development of the 750 MW Interconnection can inherently accommodate for the possibility of higher load growth. In effect the advancement of Keeyask to 2019 for exports and the interconnection provide a form of insurance for higher load growth and provide economic benefits even if the higher load growth does not materialize. Such plans are a means to reduce risks related to uncertainty in load growth, DSM and supply. (Final Argument, Section 5.4.2)

22.1.2 Economic Evaluation of Plans with Keeyask 2019 and 750 Interconnection 2020

Economic evaluations of the development plans are discussed in Final Argument, Section 10.3. The discussion below focuses on comparing plans with Keeyask and the Interconnection to those without Keeyask and the Interconnection.

MH Exhibit #104-8 provides the plan evaluations for 27 scenarios based on the most recent Keeyask and Conawapa capital costs, WPS transmission investment removed and the 2012 forecast assumptions. The Expected Values from the 27 scenarios for Plans 5 and 6 (comprising Keeyask 2019, the Interconnection and Gas) are higher than or equal to the Expected Values for the viable plans without them (i.e. Plans 5 and 6 relative to Plans 1, 2 and 8). The same conclusion holds true for the reference scenario NPVs.

MH Exhibit #171 provides plan evaluations with the 2013 reference scenario and updated capital costs along with various levels of DSM with and without additional pipeline load.

Assuming DSM level 2 both with and without the pipeline load, the Plans 5 & 6 are more economic than the All Gas Plan or the Keeyask/Gas Plan without Interconnection.

MH Exhibit #104-16 provides an Integrated Resource Planning presentation of the same 2013 updated evaluations instead using the TRC approach which enables comparisons simultaneously across the combination of supply plan options and different levels of DSM. Plans 5 and 6 at DSM Level 2 have a higher NPV benefit than any of the other combinations of viable plans and DSM levels.

Referring again to MH Exhibit #171 and assuming DSM level 2, the economic advantage of Plans 5 & 6 improve when the embedded return on equity is considered.

In MH Exhibit #171 when including cash transfers to the Province, Plans 5 and 6 have approximately $1.4 Billion greater benefit than Plan 2 (Keeyask, no Interconnection) and $2.3 Billion greater than the All Gas Plan.

The main risks can be mitigated and managed as discussed in Section 10.4.

22.1.3 Financial Evaluation of Keeyask 2019 and 750 MW Interconnection 2020

Financial evaluations of the development plans are discussed in detail in Final Argument Section 13.0. The discussion below focuses on the plans which contain Keeyask and the new 750 MW Interconnection.

Exhibits #104-12-1 to 104-12-4 provide new financial analyses for Plan 5 (Keeyask/Gas/750 with the WPS sale) under the reference scenario reflecting 2013 assumptions for the load forecast (with no new pipeline load), escalation, interest and exchange rates, electricity export prices, capital costs and DSM Level 2.

Exhibits #104-12-5 to 104-12-7 provide financial updates to plans with Keeyask and a 750 MW Interconnection (Plans 5 and 6) under reference scenario with the same assumptions noted above, as well as Plan 5 with new pipeline load.

Plans with Keeyask and a 750 MW Interconnection provide the lowest customer bills on a present value basis over the long term. Rates charged to customers are lower relative to plans without Keeyask and the 750 MW Interconnection by 2032 or Keeyask at a later date without the 750 MW Interconnection by about 2027.

22.1.4 Societal Perspective on Plans with Keeyask and New Interconnection

The other societal perspectives on the development plans are discussed in various Final Argument sections; the following discussion focuses on Plans 5 & 6.

Reliability of electrical supply to Manitobans – The plans with Keeyask and the 750 MW Interconnection provide significantly greater reliability than the plans with no new interconnection. They provide over 500 MW of additional Load Carrying Capacity to deal with supply interruptions and unexpectedly high short term load increases such as those due to an unusually severe cold snap over winter peak (LCA/MH I 037).

Energy security for Manitobans – The plans with Keeyask and the 750 MW Interconnection provide significantly greater emergency energy during droughts than the plans with no new interconnection. They provide in the order of 3,000 to 5,000 GWh of emergency energy in the event of droughts worse than the worst on record, outages of thermal generation or import lines and unusually cold winters or hot summers (LCA/MH I-037)

Socio-economic benefits in Manitoba especially to Northern and aboriginal communities – Development of Keeyask and the 750 MW Interconnection provide enhanced employment, income, training and business opportunities. The projects would have no significant residual impacts to community infrastructure, services, personal & family & community life, resource use and heritage resources (Final Argument Section 14.0).

Macro-environmental impacts and benefits - Developing Keeyask and the 750 MW Interconnection results in a major reduction in greenhouse gas emissions in Manitoba and regionally with no significant residual impacts to air, land, water, flora, fauna and key environmental functions (Final Argument Section 14.1).

22.1.5 Benefit Cost Evaluation from Overall Manitoba Societal Perspectives

The NPV evaluations discussed above are analyzed from the perspectives of Manitoba Hydro and Manitoba domestic ratepayers. The Multiple Accounts Benefit Cost evaluation by Dr. Shaffer integrates those perspectives and others into a single quantitative and qualitative evaluation. (Finance Section 13.0 and MH Exhibit #166).

The evaluation with the updated capital costs concludes that Plan 6 with Keeyask and the 750 MW Interconnection and Plans 14 and 12 which also include Conawapa, all are approximately equal in NPV at the 6% Real Social Discount Rate, approximately $400

Million more beneficial than Plan 2 (Keeyask/Gas) and $1Billion more beneficial than Plan 1 (All Gas).

When considering these quantitative results along with qualitative considerations, the Multiple Accounts Societal Benefit Cost evaluation concludes that proceeding with Keeyask and the 750 MW Interconnection is in the best interests of Manitobans considering the overall societal benefits and costs.

22.1.6 Ten Reasons to Decide Now to Commit Keeyask and Interconnection

Manitoba Hydro believes there is more than sufficient information available in the NFAT proceeding for the PUB to confidently draw conclusions and make recommendations about Manitoba Hydro's development plans.

CAC has suggested that there is insufficient information about the economic and financial evaluations and about the possibility of a better alternate export arrangement to recommend proceeding with Keeyask and the 750 MW Interconnection; instead the projects should be delayed. (CAC – Tr. p. 11149, line 18 – p. 11150, line 5)

Manitoba Hydro believes these concerns are not warranted and is confident that there is sufficient information and a strong enough rationale to proceed with Keeyask and the 750 MW Interconnection for the following ten reasons:

1) **Substantial amount of high quality information** – There is more than adequate information to make sound judgments and decisions. By Manitoba Hydro's count, there have been two pre-Hearing Conferences, four days of workshops and two rounds of Information requests with roughly 2400 responses placed on the public record. Inclusive of all the sub-parts, Manitoba Hydro filed over 300 exhibits which when combined with the Exhibits of other parties mean this Board has reviewed in excess of 500 exhibits. In addition to MH's 5000 page filing, the PUB has received 16 reports from the experts called by Intervenors and 8 reports from the IECs, plus their supplemental reports. In total there were will have been 48 public hearing days and over 13,000 pages of transcript. The PUB will have heard from 33 Manitoba Hydro witnesses and 52 Intervenor and IEC witnesses. In addition, for the first time the panel and IECs were able to review Manitoba Hydro's most commercially sensitive documents – its export contracts, its Power Resource Plan, its export price forecast and its construction contract information. No panel in the history of

Manitoba Public Utilities Board has ever reviewed a matter at this level of detail – it is unprecedented.

MIPUG quotes Mr. Bowman on this topic:

> MR. PATRICK BOWMAN: I've been through a number of different processes like this, and a lot of hearings on different subjects, and I can't remember hearing where the Board has had as high a quality of advice and information put to it as this one.
>
> I think that there has been some exceptional work done. I think you've had Manitoba Hydro's A-team in respect of economics. It's the best Manitoba Hydro has to offer, and although I'm always a skeptic about new people coming in and managing to find their feet on a system as complicated as Manitoba Hydro is, I think people like Morrison Park did a very, very good job, and I think you should -- I'll try to, as I work through my comments, not spend time dwelling on things that I think they have covered very well. (Final Argument, page 9).

2) **Ability to make reasonable inferences –** An area of information that was noted by CAC and LCA to be absent is an uncertainty matrix (or quilt) based on the 2013 Load Forecast and related assumptions rather than the 2012 assumptions. The NFAT deliberations can be informed by utilizing the reference scenario evaluations with 2013 information and updated capital costs in combination with the 2012 uncertainty matrix which also utilized the updated capital costs for Keeyask and Conawapa. (Mr. Wojczynski Tr. p 3923, line 19 to p. 3929, line 18). The latter matrix indicates how the economics of each plan are affected by variation in the three parameters of energy prices, capital cost and discount rate. The 2013 updated reference scenario evaluations provide a current set of economic results which can be used as a base starting point from which to use judgment to consider the variations indicated by the matrix. The information is not perfect but it is more than sufficient. (Tr. p. 1540, lines 3018)

   Similar comments can be made in regard to information provided for the financial and rate evaluation of the plans. While only the reference case was analyzed for these updates, they can be combined with the earlier sensitivity analysis to permit judgments on how the plans will perform financially and with respect to rates under different conditions.

3) **Deferring the decision does not eliminate uncertainty** – Deferring the decisions on Keeyask and the 750 MW Interconnection does not eliminate or even reduce uncertainty. (Tr. p. 4515-4516).

Most uncertainties will stay uncertain. For example load growth, capital costs, interest & escalation will always remain uncertain. (Tr. p. 3694, lines 18-20).

Some uncertainties will diminish but persist to a large degree. Impacts of shale gas likely will be better known but natural gas prices will still be subject the uncertainties of market forces and thus remain uncertain and volatile.

Some new factors will arise increasing uncertainty. These are the "unknown unknowns".

Perfect information is never available. The perfect is the enemy of the good is an aphorism or proverb meaning that insisting on perfection often results in no improvement at all. While there are remaining uncertainties and it is always helpful to be able to have additional information to inform a decision, it is impractical and imprudent to insist on trying to have a perfect set of information and comparisons. Good management and optimization of benefits to Manitobans require making a judgment as to whether there is adequate information to make a decision and then use judgment to make a reasoned decision. Time does not stand still while decisions are being considered, and the Board, like Manitoba Hydro, must make its judgments based on the information available to it. (Mr. Todd, Tr. p 4962, lines 1-10, Mr. Peaco, Tr. p. 6099 lines, 20-24, Mr. Gibson, Tr. p. 9296-9297).

Dr. Borison provides a thorough discussion of this issue at Transcript pages 2560:2561:

DR. ADAM BORISON: ...this is an industry that has been, for decades, quite dynamic, quite changing, and quite uncertain. And that I was looking back in the literature for the use of the term 'unprecedented uncertainty', which I have used, and Dr. Murphy has used. And I found that in every single year, at least going back ten (10) years on the Internet, and then I actually found an article from 1983 about -- that said the -- the utility industry is facing unprecedented uncertainty. But I actually don't think that's untrue. I think what 'unprecedented' means in that context is there are a set of things that appear very uncertain right now that -- that haven't been there before. And so in '83 it were -- was things like Three Mile Island, or something of that nature, electromagnetic fields. There were issues that were there that people had never heard about before which all of a sudden made things very uncertain. I think the -- the fantasy though is that -- that somehow those are going to go away."

Although the 250MW sale agreement with Minnesota Power includes delay provisions tied to the start of Keeyask, exercising them for the purpose of studying other alternatives will greatly increase uncertainty for Minnesota Power and the Minnesota Public Utilities Commission, raising concerns and putting into question whether to proceed with the 750 MW interconnection. Any indication that Manitoba is delaying and is uncertain whether to commit to Keeyask is likely to result in a suspension of its 750 MW interconnection development and permitting activities including the public hearing scheduled to commence in August of 2014.

4) **The Interconnection provides flexibility to manage uncertainty** – While there are uncertainties, the development of the interconnection facilitated by Keeyask is a means to provide options and flexibility to respond to, adapt to, to manage and to take advantage of the uncertainties. The pathways have demonstrated how the interconnection assists in managing risks and opportunities. If energy prices or carbon regulation increase, Conawapa can be developed; if not, Conawapa does not need to proceed. If export contract negotiations are successful, or net load growth increases greatly, Conawapa can proceed. If net load growth diminishes, system surplus from Keeyask and DSM can be exported over the expanded interconnection. If climate change causes increased water supply, the interconnection assists in exporting the additional surplus hydro energy. If climate change causes more severe droughts, the interconnection and expanded hydro can provide additional emergency energy during droughts to Manitoba domestic customers. (Mr. Peaco, Tr. p. 5995, lines 4-12, Mr. Tyson, Tr. p. 7021, lines 17-23, Mr. Bowman, Tr. p. 10040, lines 15-25, Mr. Wojczynski, Tr. p. 2302, line 13 – p. 2303, line 12).

5) **Keeyask and the 750 MW Interconnection economic over wide range of net loads** – An area of concern in the NFAT process has been the uncertainty in future net load growth given the inevitable variation in gross load growth and the added uncertainty as to how much DSM potential there is in the future. While the economics of adding Conawapa is affected by assumptions as to future net load growth, studies indicate that the economics of developing Keeyask with the Interconnection are remarkably stable. The reference scenario evaluations result in approximately a $400 Million NPV benefit from the MH perspective regardless of whether DSM is assumed to be

base, Level 1, 2 or 3 and whether pipeline load is included or not. The NPV is also approximately $400 Million in the sensitivity evaluation where net load growth was assumed to flatten to zero and Keeyask became a pure merchant plant (Tr. p. 9947-9948).

6) **The window of opportunity for developing the 750 MW interconnection infrastructure is time limited** – The confluence of factors which enable the opportunity will likely not remain for an extended time:

- US utilities need change in supply mix away from coal generation
- US utilities want to avoid overexposure to natural gas generation and are making strategic decision now
- In the US, regulators, government & MISO are favorably disposed to the 750 MW interconnection project and Keeyask imports due to the wind synergies resulting from hydro and transmission expansion
- Minnesota Power is willing to develop the 750 MW interconnection now and is in the midst of the regulatory proceeding for the interconnection
- Manitoba Hydro has preferential positioning for firm transmission service into Wisconsin with MISO that will be lost if the transmission requests have to be resubmitted at later date;
- Keeyask project is construction ready and supported by First Nation partners
- Currently there is a low interest rate environment for Manitoba Hydro to commit 30 year bonds while in future years interest rates may be higher

(Mr. Wojczynski, Tr. p. 306 line 12 – p. 307 line 20, Tr. p. 2308 lines 15-25, Tr. p. 3693 line 11 – p. 3694 line 17)

7) **An infinite circle of information** – CAC suggests that given the MP 250MW contract has a provision to allow for up to a two year delay, there is time to hold another NFAT process in which Manitoba Hydro ought to be required to provide economic and financial uncertainty evaluations with updated capital costs and 2013 forecast information to supplement the evaluations done for the reference scenario. If such a process were followed it is inevitable that once the NFAT#2 process were underway there would be requests to update the reference scenario evaluations for 2014 forecasts of loads and other parameters and once those were available there would be requests for the other 26 scenarios and by the time all this was available and under review there would be demands for 2015 updates. This would become an infinite circle.

8) **A Bird in Hand** – The reality is that MH has undertaken much effort and investment to create a viable commercial opportunity which is indicated by studies to benefit Manitobans over a wide range of perspectives. The opportunity before us today with Keeyask and the interconnection is a known quantity with certainty as to its existence. To seek an alternative in the hope that there might be a better new arrangement places the onus on there being strong evidence supporting the existence, viability and benefits of this other alternative. This was strongly supported by Mr. Colaiacovo of MPA (Tr. p. 7614) and confirmed later in the MPA May 23 Supplement Report:

"MR. PELINO COLAIACOVO: … our point was that given all of the money that's been spent on Keeyask, given the commercial arrangements that have been a made for Keeyask, a decision to not proceed has to -- could only occur if there was very, very strong evidence that not proceeding would be advantageous to the ratepayer and to other stakeholders. That it's not sufficient to say that financial modeling, or economic modeling suggests that All Gas is preferable to -- to going ahead with Keeyask on some narrow basis. That the burden of proof, frankly, lies on people who question the decision to go forward with Keeyask, to demonstrate that other options are conclusively better. If they can't demonstrate that their -- their other options are conclusively better, then Keeyask is the real option that -- that is before the Government of Manitoba, is before the NFAT process. There has been some new information. The cost of Keeyask has gone up. It's legitimate to recalculate numbers to ensure that those -- that new information doesn't change all of the analysis that's happened so far to date."

9) **Cancelling Contracts Now Would Harm Manitoba Hydro Commercial Credibility** – Deferring Keeyask and cancelling the export contracts which have been negotiated for over six years would harm the credibility and trust Manitoba Hydro has with counterparties in the export market regarding the ability of Manitoba Hydro to carry through and deliver on such arrangements. While this would not harm the willingness of counterparties to arrange short term exports it likely would impede long term contractual negotiations. This would harm the ability to secure favorable long term export contracts to the detriment of future export revenues. Mr. Coloaiacovo from MPA explains (Tr. p. 7255, line 4):

> "there is also an issue of the commercial reputation of Manitoba Hydro and its ability to do business in the future. It has been working for a number of years on the Keeyask project, the intertie project, and the export contracts. It's been working with a wide variety of parties who

have come to the table in good faith and negotiated these arrangements on the assumption that there was an ability to actually execute on them. That is not determinative. Deals fail all the time in the world. But when deals fail there are consequences to deal failure. And those are -- consequences are not always easily calculated in dollar terms. There is a loss of reputation, and there is a loss of the ability to do business. None of the alternative plans of the many different alternative plans that have been put before the panel address that issue. There is a cost consequence in terms of the writing off of some costs, but there is no additional cost burden that is understood to be related to the commercial consequences of the collapse and cancellation of the plans."

10) **Deferring Keeyask Increases Capital Cost** – Deferral of Keeyask would involve increased capital costs due to real escalation in costs, additional activity required to maintain the project readiness and interest on expenditures. A one year deferral has been estimated to increase the In-service cost $250 to $300 Million. Each additional year of delay would entail further and similar cost increases.

22.1.7 NFAT Participant Support for Keeyask and 750 MW Interconnection proceeding

A common position of most participants is that adding additional interconnection capacity to utility grids whether in Manitoba or elsewhere is generally overall beneficial in terms of enhanced efficiency in electrical system development and operation and enhanced reliability. (MPA - Tr. p. 7293, line 15 – p. 7295, line 19, Bowman - Tr. p. 10064, lines 12-15, GAC - Tr. p. 9788, line 17 – p. 9790, line 11, Mr. Russell Tr p. 10631, line 24).

> "But the fact of the matter is having interconnections – and this is one (1) of the major advantages of interconnections – is that you can rely upon your neighbours. There's a long history in the industry of doing so. And indeed, in the NFAT, I quote in my report portions where Manitoba Hydro cites just this kind of opportunity is being available from enhanced interconnections."

A number of participants support the specific proposal by MH to advance Keeyask to 2019 and develop the 750 MW interconnection.

Independent Expert Consultant Mr. Colaiacovo on April 17 supported proceeding with Keeyask and the 750 Interconnection (Tr. p. 7614).

> "MR. PELINO COLAIACOVO: … Should Keeyask proceed or not? I -- our point was that given all of the money that's been spent on Keeyask, given the commercial arrangements that have been a made for Keeyask, a decision to not proceed has to -- could only occur if there was very, very strong evidence that not proceeding would be advantageous to the ratepayer and to other stakeholders. That it's not sufficient to say that financial modelling, or economic modelling suggests that All Gas is preferable to -- to going ahead with Keeyask on some narrow basis. That the burden of proof, frankly, lies on people who question the decision to go forward with Keeyask, to demonstrate that other options are conclusively better. If they can't demonstrate that their -- their other options are conclusively better, then Keeyask is the real option that -- that is before the Government of Manitoba, is before the NFAT process. …
>
> And therefore a judgment to not proceed with it has to be made with strong evidence and strong grounds. And all of the financial modelling and analysis that we did as part of this process suggests there isn't that strong evidence and strong grounds based on the data we had. And we came to the conclusion, therefore, that, in our view, commercially Keeyask makes sense as a project to go forward with based on that analysis and information."

MPA in their May 23 supplemental report (Page 43) confirmed that they continue to hold the view that proceeding with Keeyask for 2019 and the 750MW Interconnection for 2020 is warranted.

MIPUG expert witness Mr. Bowman concluded the plans with Keeyask 2019 and the 750MW Interconnection should proceed (MIPUG Exhibit #24, Slide 65)

> "Pursue Keeyask, MP 250, 750 MW T-Line"

MIPUG in its Final Argument also supported proceeding with Keeyask 2019 and the 750 MW Interconnection as long as some modifications were made to improve benefits sharing between the Province and Manitoba Hydro and as long as there was some temporary relaxation of the Manitoba Hydro financial targets, (Mr. Antoine Hacault, TR page11234, line 9):

> "So moving to the second subject on our one (1) page summary, Keeyask19 with a 750 megawatt line could be preferred, but needs revised benefit sharing to achieve fairness."

CAC takes the position in final argument that it is premature to conclude whether Keeyask should proceed in the near term with the 750 MW Interconnection and that MH should be directed to provide additional information to a second NFAT process. CAC takes this position despite the fact that two of their own expert witnesses (Harper and Higgin) concluded that plans with Keeyask and the 750 MW Interconnection were the most economic of the plans.

CAC witness Mr. Harper on April 26(TR page 8552, line 19, CAC Exhibit #68, slide 61) supported the position that plans with Keeyask 2019 and the 750MW Interconnection are more economic than plans without the interconnection.

- "From information available to-date advancing Keeyask/750/gas-based plan appears economic relative to plans with no intertie
  - supported by the updated 2012 uncertainty analysis
  - the 2013 reference case results indicate that at dsm2 levels these economics will improve"

CAC witness Dr. Higgin (TR page 9477, line 11, CAC Exhibit #76, slide 18) supported proceeding with Keeyask 2019 and the 750MW Interconnection:

> "So I would tell my client, I think because of the terms of reference, the path should be DSM for domestic need, and Keeyask for export opportunity with the intertie, with certain conditions to be met in the 2015 period.

GAC in its Final Argument also supported proceeding with Keeyask 2019 and the 750MW Interconnection (GAC Exhibit #27, page 29-30)

> "The PUB should approve Keeyask and the 750 MW transmission intertie to Duluth for immediate construction.
>
> The new 750 MW intertie to Minnesota (expandable to 1100 MW), with complementary reserved transmission to Wisconsin, is the most important asset in Hydro's plans. It has net benefits to Manitoba and contributes to

regional sustainability, including facilitation of economic firm exports, economic imports (particularly in drought conditions and to meet winter peak load, but also for profitable resale on-peak), enhancing other renewable resources by firming wind and solar power, and enhancing the reliability of domestic power supply. While the evidence in support of Keeyask for domestic need is more equivocal and the analysis under flat loads is sketchy, Green Action Centre believes that Keeyask is likely to be justified for exports, especially because a commitment to that plant appears to be necessary to promote the prompt construction of the intertie and it already has its capacity contracted out in profitable sales for the early years."

22.1.8 Development of Keeyask 2019 and 750 MW Interconnection 2020 is Justified.

Keeyask construction for a 2019 ISD and development of the 750 MW Interconnection for a 2020 ISD is justified. This pathway includes the associated long-term export contracts (MP 250 MW, WPS 100 MW and WPS 308 MW, NSP 125 MW extension) and the expanded DSM plan. The pathway meets the electricity needs of Manitobans and is in the best long-term interest of Manitobans and the province of Manitoba when compared to other options and alternatives.

Risks associated with advancing Keeyask and development of the 750 MW Interconnection have been evaluated and can be mitigated and managed, refer to Final Argument Section 10.4 and Section 13 (Financial Risks)

Plans with Keeyask and the 750 MW Interconnection are shown to result in the lowest long term cost of supply for Manitoba Hydro; are favourable in the long term to ratepayers; provide significant benefits to the provincial government through financial transfers; provide reliability and energy security benefits to Manitoba domestic electricity consumers; provide a large reduction in GHG emissions; and overall provide the most socio-economic benefits to Manitobans, especially Northern and Aboriginal communities, including employment, income, training, business opportunities and capacity building.

22.2 Conawapa Recommendations & Justification

This section addresses the recommendation as to whether Conawapa should proceed in the event that Keeyask is committed for a 2019 ISD and the 750MW Interconnection is committed for a 2020 ISD.

The most current information indicates that proceeding with Conawapa for an ISD earlier than required for domestic load would be economic from the Manitoba Hydro perspective in the likely situation that current negotiations on additional long term export contracts are favourable. Proceeding with Conawapa would also provide incremental benefits to the provincial government though cash transfers, provide a larger reduction in GHG emissions and from an overall perspective provide the most socio-economic benefits to Manitobans especially Northern and aboriginal communities.

Under the reference scenario, the direct economic benefit to Manitoba Hydro for the plans with Conawapa is only greater than the plans without Conawapa if the embedded return on equity is considered. Plans with Conawapa as a resource also have higher downside risks and incur higher mid-term rate increases. However, the direct benefits to Manitoba Hydro and ratepayers are expected to be higher than identified in the current evaluations because it is expected that negotiations and discussions currently underway with US and Saskatchewan utilities will be successful and increase the benefits while reducing risks (Final Argument Sections 6 and 8.5, Higgin TR page 9500 line 22). The direct benefits would also significantly rise in scenarios with higher export prices, lower interest rates and /or lower capital costs.

Fortunately, a decision to commit construction of Conawapa does not need to be made for several years. By 2017 or early 2018 there will be better information on these potential sales and on US approvals for the proposed 750MW tieline. As discussed in Section 16.2, Manitoba Hydro will intensively monitor the Conawapa business case to determine the appropriate early ISD to protect for Conawapa and to delay or halt Conawapa if the favourable business case does not materialize as expected.

22.3 Economic Evaluation of Conawapa Benefits to Manitoba Hydro

Economic evaluations of the development plans are discussed in Final Argument Section 10.3. This discussion below focuses on the Conawapa plans.

MH Exhibit #104-8 provides the plan evaluations for 27 scenarios based on the most recent Keeyask and Conawapa capital costs, WPS transmission investment removed and 2012 forecast assumptions. The expected value of the 27 scenarios for plans with Conawapa are lower than the plans without Conawapa (i.e. Plan 14 relative to Plan 5, Plan 12 relative to Plan 6.) As noted, there is considerable upside NPV opportunity for the Conawapa plans in scenarios such as with high export prices, low capital costs and/or low discount rates.

Furthermore the Conawapa plan economics would improve and the risk diminish if, as expected, additional export contracts are successfully negotiated.

MH Exhibit #171 provides plan evaluations with the 2013 reference scenario and updated capital costs along with various levels of DSM both with and without additional pipeline load. Assuming DSM level 2 with or without the pipeline load, the Conawapa plans approximately meet the NPV test relative to the All Gas Plan but are less economic than the Keeyask/Interconnection plans without Conawapa. Assuming DSM level 2, the Conawapa plans have approximately the same or greater benefits than the Keeyask/Interconnection plans without Conawapa if the embedded return on equity is considered.

The most powerful economic argument for maintaining Conawapa as an option lies in the analysis which includes economic benefits to the Province as a whole. In MH Exhibit #171, plans with Conawapa have significantly greater benefits when including cash transfers to the province: $0.7 Billion under DSM 2 with no pipeline load, $1.4 Billion under DSM 2 with pipeline load and up to $2.1 Billion for Base DSM with no pipeline load. Plans which include Conawapa are also distinguished by an increased number of jobs, economic spinoff and opportunities for Northern and aboriginal communities.

The aforementioned scenarios with upside assumptions are ones where there would clearly be the full suite of benefits arising from plans with Conawapa. It is recognized that there are also scenarios with downside risks in which Conawapa would not have the economic benefits to Manitoba Hydro although most of the other societal benefits would still occur. Manitoba Hydro believes that these risks can be mitigated and are manageable as discussed in Section 10.4.

There has been confusion as to the situation regarding the WPS 308 MW sale and Conawapa. As explained in the Final Argument Introduction, the WPS sale contract is a finalized and signed contract but the delivery of exports under the contract are determined by various contract conditions. One condition is that delivery is contingent on four Conawapa units being in-service by 2031. Should the units be in by that time and the 750 MW interconnection be in place, then the WPS sale deliveries are to occur. Should MH choose not to develop Conawapa for that time period, the parties may mutually agree to amend the WPS contract to allow it to proceed, or, in the event the parties do not agree, the sale agreement will terminate.

22.4 Financial Evaluation of Conawapa Plans

Financial evaluations of the development plans are discussed in detail in Final Argument Section 13; the following discussion focuses on the Conawapa plans.

Exhibits #104-12-1 to 104-12-4 provide an update to Plan 14 (reference scenario) reflecting 2013 assumptions, updated capital costs and DSM Level 2. Exhibits #104-12-5 to 104-12-7 provide an update to Plan 12 (reference scenario) with the same assumptions noted above, as well as Plan 14 with new pipeline load.

In the long term, rates charged to customers for plans with Conawapa are lower than other plans. However, cumulative rates for plans with Keeyask and an Interconnection are lower than plans with Conawapa in the medium term. While plans with Keeyask and an interconnection have a lower NPV of consumers' revenue than the plans that also have Conawapa, the Preferred Development Plan has significantly lower cumulative rate increases by the end of the of study period, 96% versus 130% (shown in MH Exhibit #104-12-5, p.3 above).

As with the economic analysis, there is sufficient evidence to indicate potential upside to ratepayer benefits for plans with Conawapa in addition to the benefit to Manitoba as a whole to continue to protect the optionality of Conawapa.

22.5 Societal Perspective on Conawapa Plans

The other societal perspectives on the development plans are discussed in various Final Argument sections. The following focuses on the Conawapa plans.

Socio-economic benefits in Manitoba especially to Northern and Aboriginal communities- Development of Conawapa provides enhanced employment, income, training and business opportunities with no significant residual impacts to community infrastructure, services, personal & family & community life, resource use and heritage resources. (Final Argument Section 14)

Macro-environmental impacts & benefits- Developing Conawapa in addition to Keeyask results in approximately a doubling in the reduction in greenhouse gas emission in Manitoba and regionally with no significant residual impacts to air, land, water, flora, fauna & key environmental functions (Final Argument Section XXX)

22.6 View of NFAT Participants on Conawapa Advancement

A position of several participants is that the full justification for proceeding with Conawapa has not been established but that it is possible that the justification will be there once more information is available on the success of negotiations on the export contracts and on future export prices.

MIPUG takes the position in its Final Argument (page 59) that the potential for the Conawapa project proceeding for 2026 should not be abandoned. MIPUG suggests that there should be limitations on Conawapa spending and timing.

As described in Section 16.2 there will be extensive monitoring of Conawapa activities and expenditures. Manitoba Hydro expects that there will be sufficient progress on the export contract negotiations early enough that the four years of protection and investment will not be required to be in a position to make decision on Conawapa. However, Manitoba Hydro suggests that setting some form of cap on such time frame and investment is not appropriate given that the business case at the time should be the determinant of decision on Conawapa protection. It would not be practical or prudent to recommend a funding cap or time limitation to government.

In its May supplementary report (page 4), MPA supports continued protection of Conawapa:

> "Conawapa as a competing alternative for future generation:
> MPA continues to support its comments to the PUB that Conawapa should be considered a development opportunity, competing with other potentially superior alternatives, and continued expenditures to develop Conawapa should be justified in that light."

22.7 Conclusion: Conawapa Advancement for Exports Likely Warranted

The NFAT TOR includes Conawapa as well as Keeyask and the rest of the Preferred Development Plan. As discussed in the Final Argument Introduction and Section 16.2, no decision on committing Conawapa construction is required for at least several years. If the upside opportunities to the Conawapa business case do not arise due to failure of the current export contract negotiations and /or other conditions occur which are unfavorable to the business case, the Conawapa protection activities would be halted and Conawapa would not proceed.

This creates a somewhat different situation for the PUB NFAT report and recommendations than is the situation regarding Keeyask. Manitoba Hydro had been asked under what conditions Conawapa should be approved and Manitoba Hydro suggested that it would be reasonable for Conawapa to proceed if, at the time of commitment, the trajectories of economics are not significantly adverse compared to what we're looking at in the NFAT evaluations and if some of the positive upsides happen as we expect will happen as a result of successful negotiation of additional export sales contracts (Wojczynski, TR pp 4240:4241)

> "First of all, Manitoba Hydro is quite aware that for a decision out in 2018 or the end of 2017, that whole timeframe, that given the uncertainties that -- to have an unqualified endorsement and that -- and let me exaggerate to make the point, to say, no matter what happens, Conawapa should proceed, and we agree that that is not something Manitoba Hydro's asking for or looking for. And -- but something that is more along the line of -- if the trajectories of economics are not significantly adverse compared to what we're looking at and if some of the positive upsides happen as we expect will happen with some of this additional sales and that -- then that it would be reasonable for Conawapa to proceed. I think something in that realm would be what Manitoba Hydro would reasonably be looking for this panel to be commenting on. We recognize, Mr. Chair and panel, that given there are a few years to go, a totally unqualified endorsement is -- is not something that would be reasonable to -- to ask for. But to give an indication of the reasonability or proceeding in the more positive portion of the -- the circumstances that happen and can happen in the future, I think would be something that would be reasonable and -- and Manitoba Hydro is looking for."

Assuming that previously Keeyask has been committed for a 2019 ISD and the 750MW Interconnection committed for a 2020 ISD, it is in the interests of Manitobans for to maintain Conawapa as an option and to plan for the possibility that it may be developed for export earlier than needed for domestic load. As noted, Conawapa has significant provincial and macroeconomic benefits. It is worth maintaining this option for a few more years to confirm the expectation that additional export opportunities will emerge, allowing the project to capitalize on its significant upside.

TABLE OF CONCORDANCE

The following table details each component of the mandate given to the PUB by the NFAT Terms of Reference, and provides the location within Manitoba Hydro's Written Final Submission where the item is addressed. Some components are also dealt with in the separate Final Argument Submission from the Keeyask Cree Nations.

Terms of Reference	Addressed in Final Argument Sections and Subsections
Recommendations to the Government of Manitoba on the needs for Hydro's preferred development Plan	5.1,5.4,5.6,12,22.1.1
An overall assessment as to whether or not the Plan is in the best long-term interest of the province of Manitoba when compared to other options and alternatives.	19,22
1. An assessment as to whether the needs for Hydro's Plan are thoroughly justified and sound, its timing is warranted, and the factors that Hydro is relying upon to prove its needs are complete, reasonable and accurate. The assessment will take the following factors into consideration:	2,3,4,5,7,8,9,11,12,22.1.1
a) The alignment of the Plan to Hydro's mandate, as set out in Section 2 of the Manitoba Hydro Act;	5.3, 5.4
b) The alignment of the Plan to Manitoba's Clean Energy Strategy and the Principles of Sustainable Development as outlined in The Sustainable Development Act.	15, 16, 17,18
c) The extent to which the Plan is needed to address reliability and security requirements of Manitoba's electricity supply.	5, 7, 11, 12 ,22.1.1
d) The reasonableness, thoroughness and soundness of all critical inputs and assumptions Hydro relied upon for its justification of its needs. This should include Hydro's planning load forecast and future load scenarios,...	2,3,4,5
...its demand and supply analysis,...	5.3,5.4, 6
...export expectations and commitments,....	9.1, 9.2, 8.3, 8.4
...demand side management and conservation forecasts.	2,3,4, 5.4

Terms of Reference	Addressed in Final Argument Sections and Subsections
2. An assessment as to whether the Plan is justified as superior to potential alternatives that could fulfill the need. The assessment will take the following factors into consideration: a) If preferred and alternative resource and conservation evaluations are complete, accurate, thorough, reasonable and sound;	 5,6,8,10,11,13,21,22
b) The alignment of the Plan and alternatives to Manitoba's Clean Energy Strategy, The Climate Change and Emissions Reduction Act and the Principles of Sustainable Development as outlined in The Sustainable Development Act;	15, 16, 17, 18
c) The accuracy and reasonableness of the modeling of export contract sale prices, terms, conditions, scheduling provisions, export transmission costs, and the reasonableness of projected revenues;	5.5,7,8,.3,8.4,8.5,8.6,9.1.2
d) The reasonableness of forecasted critical inputs including construction costs,	6
…opportunity export revenues,…	9
… future fuel prices,…	9
…electricity market price forecasts,…	9
…the determinants of those values,…	9
…and export volumes;	5
e) The reasonableness of the scope and evaluation of risks and the benefits proposed to arise from the development and the reasonableness and the reliability of Hydro's interpretation of the most likely future outcomes as a result of climate changes, interest rate fluctuations, export market prices, domestic load fluctuations, droughts, competing technologies, fuel prices, carbon pricing, technology developments, economic conditions, Hydro's transmission positions and other relevant factors;	5,10,11,12,13,17,22
f) The impact on domestic electricity rates over time with and without the Plan and with alternatives;	13
g) The financial and economic risks of the Plan and export contracts and export opportunity revenues in relation to alternative development strategies;	8.3, 9.1.1.3, 10, 13
h) The socio-economic impacts and benefits of the Plan and alternatives to northern and aboriginal communities;	14,19,20
i) The macro environmental impact of the Plan compared to alternatives;	14

Terms of Reference	Addressed in Final Argument Sections and Subsections
j) If the Plan has been justified to provide the highest level of overall socio-economic benefit to Manitobans, and is justified to be the preferable long-term electricity development option for Manitoba when compared to alternatives.	19,22

November 2009

Capital Expenditure Forecast (CEF09-1)

2009/10 - 2019/20

Corporate Controller Division

Finance & Administration

Foreword

The *Capital Expenditure Forecast* (CEF09-1) is a projection of Manitoba Hydro's capital expenditures for new and replacement facilities to meet the electricity and natural gas service requirements in the Province of Manitoba as well as expenditures required to meet firm sale commitments outside the province. Expenditures included in the Capital Expenditure Forecast will provide for an ongoing safe and reliable supply of energy in the most efficient and environmentally sensitive manner.

The *Capital Expenditure Forecast* is comprised of a number of specifically identified large projects or "major items" as well as numerous unspecified smaller projects referred to as "domestic items." Major items are normally over $2 million in total cost and the construction period on each major item usually extends beyond one year. Domestic items typically represent the ongoing and recurring capital requirements to meet electricity and natural gas service replacements and expansions throughout the province. All major and domestic capital projects are subjected to a rigorous review and approval process before being included in the *Capital Expenditure Forecast*.

In constructing and maintaining its capital facilities, Manitoba Hydro adheres to the principles of sustainable development. For example, the Corporation is committed to reduce the net emissions from its own facilities and to contribute towards global emission reductions through the export of renewable electricity. Manitoba Hydro exceeded its past voluntary commitment to reduce its average net greenhouse gas (GHG) emissions from 1991 to 2007 to 6% below 1990 levels. Manitoba Hydro also has a separate contractual commitment under its participation in the Chicago Climate Exchange (CCX) to progressively reduce its generation related emissions until 2010. The Corporation is in full compliance with the CCX target.

Manitoba Hydro has one of the most aggressive Demand Side Management (DSM) programs in North America. The target to be achieved by 2025 is for electrical savings of 915 MW and 3,271 GWh, and natural gas savings of 172 million cubic meters. In total, Manitoba Hydro's DSM programs are expected to result in greenhouse gas emission reductions of nearly 2.5 million tonnes annually by 2025.

Capital Expenditure Forecast Summary Table

1.0 Overview

Capital Expenditure Forecast Summary

This Consolidated Capital Expenditure Forecast (CEF09-1) totals $16 480 million for the 11 year period to 2019/20. Expenditures for Major New Generation & Transmission and the New Head Office total $11 763 million, with the balance of $4 717 million comprised of expenditures for infrastructure renewal, system safety and security, new and increasing load requirements, and efficiency improvements.

Comparison to CEF08

The Capital Expenditure Forecast (CEF09) for the ten year period ending 2018/19 totals $15 189 million compared to $15 358 million for the same ten year period included in last year's Capital Expenditure Forecast (CEF08).

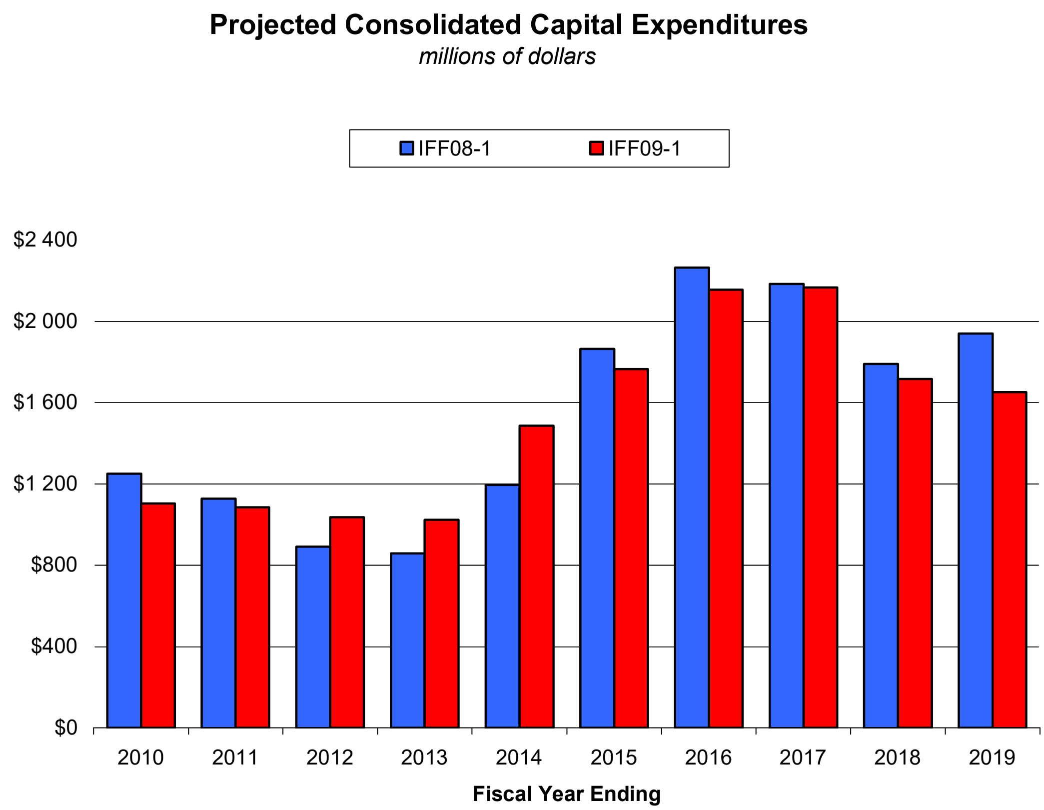
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	10 Year Total
CEF08	1 248	1 127	891	858	1 196	1 864	2 263	2 183	1 790	1 938	15 358
Increase (Decrease)	(144)	(42)	145	167	290	(99)	(107)	(18)	(74)	(287)	(169)
CEF09	1 104	1 085	1 036	1 025	1 486	1 765	2 156	2 165	1 716	1 651	15 189

The decrease of $169 million in capital expenditures over the ten year forecast period is comprised of the following:

	10 Year Increase
Keeyask Generating Station	$ 792
Demand Side Management - Electric	57
13.2 kV Shunt Reactor Replacements	33
System Refurbishment and Other Projects	184
Conawapa Generating Station	(224)
Pointe du Bois Improvements & Upgrades	(500)
Target Adjustment	(511)
	$ (169)

New energy resources are required to meet forecasted domestic requirements by 2022/23. Some of the key assumptions underlying future spending on new generation and transmission include:

- The in-service date (ISD) of the Wuskwatim Generating Station will be September 2011.
- Kelsey generating station to be upgraded by 77 MW by 2012/13.
- Bipole 3 is assumed to follow a route west of the Interlake and this route will require 2 000 MW of converters to operate, with an in-service date of October 2017.
- Manitoba Hydro has signed term sheets with Northern States Power (NSP) for 375/500 MW starting in 2015, Wisconsin Public Service (WPS) for 500 MW starting in 2018, and Minnesota Power (MP) for 250 MW starting in 2022 (for firm power).
- Keeyask and Conawapa are necessary to meet domestic load requirements and export sales commitments and have first power in-service dates of December 2018 and May 2022, respectively.



The following table provides a listing of each capital project with a forecast of expenditures for each year to 2019/20. The subsequent section provides high-level descriptions of each capital project with brief justifications and comparisons to the previously approved capital expenditure forecast.

Section 2

Project Summaries

Electric

Gas

ELECTRIC OPERATIONS:

MAJOR NEW GENERATION & TRANSMISSION:

Wuskwatim - Generation

Description:
Design and build the new Wuskwatim Generating Station with three generators and installed capacity of approximately 200 MW on the Burntwood River upstream of Thompson.

Justification:
This project increases generation for both export power purposes and domestic load requirements.

In-Service Date:
First power September 2011.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 1 274.6	$ 326.9	$ 256.4	$ 126.8	$ 20.8	$ -	$ -
Increase (Decrease)	-	37.5	18.9	(21.7)	(8.7)	-	-
Revised Forecast	$ 1 274.6	$ 364.4	$ 275.3	$ 105.1	$ 12.1	$ -	$ -

Wuskwatim - Transmission

Description:
Design and build the associated transmission facilities necessary to integrate the Wuskwatim Generation Station into the Manitoba Hydro 230 kV transmission network.

Justification:
The existing 230 kV transission system in Northern Manitoba does not have sufficient capacity to accommodate the additional output of the Wuskwatim Generating Station. This project will increase the ability of the transmission system to carry the full output of Wuskwatim to load anywhere in Manitoba.

In-Service Date:
September 2011.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 316.3	$ 52.5	$ 32.2	$ 15.5	$ 0.9	$ -	$ -
Increase (Decrease)	-	37.6	(1.7)	3.4	(0.9)	-	-
Revised Forecast	$ 316.3	$ 90.1	$ 30.5	$ 18.9	$ -	$ -	$ -

Herblet Lake - The Pas 230 kV Transmission

Description:
Perform environmental assessments and route selection, design and construct transmission and terminal facilities to provide firm supply to Flin Flon Cliff Lake and The Pas Ralls Island as follows: *Transmission*: 230 kV line 160 km from Herblet Lake to The Pas Ralls Island. *Terminations*: Extend 230 kV facilities at Herblet Lake and The Pas Ralls Island stations. *Communications*: Upgrade and co-ordinate with existing Herblet Lake and The Pas facilities.

Justification:
The line is required to provide firm supply and voltage support for increasing Flin Flon and The Pas area loads. In addition, this line facilitates the transmission of power from the Wuskwatim Generating Station.

In-Service Date:
September 2011.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 93.2	$ 39.3	$ 29.0	$ 4.2	$ -	$ -	$ -
Increase (Decrease)	-	2.6	1.4	3.0	1.9	-	-
Revised Forecast	$ 93.2	$ 41.9	$ 30.4	$ 7.2	$ 1.9	$ -	$ -

Keeyask - Generation

Description:
Design and build the Keeyask Generating Station with seven generators and installed capacity of approximately 630 MW on the Nelson River downstream of Thompson. Project costs include activities necessary to obtain approval and community support to proceed with the construction of the future generating station. The estimate is comprised of costs associated with extensive First Nations and other community consultations, pre-project training, joint venture business developments, environmental studies, impact statement preparations, submissions, regulatory review processes, detailed pre-engineering requirements, acquiring all necessary licensing, the design and construction of associated transmission facilities, and improvements to access roadways.

Justification:
This project increases generation for export power purposes and ultimately domestic load requirements.

In-Service Date:
First power December 2018.

Revision:
Estimate updated to reflect the acquisition of all necessary licensing, the design and construction of associated transmission facilities, and improvements to access roadways.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 3 700.4	$ 25.9	$ 33.1	$ 36.1	$ 64.3	$ 220.3	$ 2 974.9
Increase (Decrease)	891.2	41.8	51.9	159.2	134.3	(38.0)	504.1
Revised Forecast	$ 4 591.6	$ 67.7	$ 85.0	$ 195.3	$ 198.6	$ 182.3	$ 3 479.0

Conawapa - Generation

Description:
Design and build the Conawapa Generating Station with ten generators and installed capacity of approximately 1,300 MW on the Nelson River downstream from Thompson. Project costs include activities associated with extensive First Nations and other community consultations, pre-project training, environmental studies, impact statement preparations, submissions, regulatory review processes, acquiring all necessary licensing, improvements to access roadways, and detailed pre-engineering required to obtain a license and all necessary approvals to construct the Conawapa Generating Station.

Justification:
This project increases generation for both export power purposes and domestic load requirements.

In-Service Date:
First power May 2022.

Revision:
Estimate updated to reflect current market conditions along with the addition of access roadway improvements.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 4 978.4	$ 60.5	$ 60.7	$ 57.7	$ 62.3	$ 67.7	$ 3 705.7
Increase (Decrease)	1 346.4	(0.1)	(0.3)	17.3	49.5	122.4	(634.3)
Revised Forecast	$ 6 324.8	$ 60.4	$ 60.4	$ 75.0	$ 111.8	$ 190.1	$ 3 071.4

Kelsey Improvements & Upgrades

Description:
Overhaul and uprate all Kelsey generating station units (1-7) including the replacement of turbine runners, bottom rings, discharge rings or weld overlays, transformers, generator windings and exciters. Perform model testing to refine runner design, perform unit 1 to 7 draft tube modifications, perform unit 1 to 5 intake gate rehabilitation, and upgrade rail spur and overhead crane. Upgrade transmission facilities necessary to integrate the additional Kelsey generation into the Manitoba Hydro system network.

Justification:
Rerunnering presents the best economic solution for increasing efficiency at the Kelsey Generating Station and for adding system capacity without flooding or requiring a new water power license. Overhauling the units will improve the unit output by up to 11 MW per unit. The transmission upgrade of a portion of the Kelsey 138 and 230 kV buses and the revisions to the Northern AC Cross Trip scheme are required to accommodate the 77 MW of additional Kelsey output.

In-Service Date:
March 2012.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 189.6	$ 45.8	$ 7.4	$ 0.3	$ -	$ -	$ -
Increase (Decrease)	-	(0.7)	(0.6)	0.2	-	-	-
Revised Forecast	$ 189.6	$ 45.1	$ 6.8	$ 0.5	$ -	$ -	$ -

Kettle Improvements & Upgrades

Description:
Rewind stator for units 5-12, and install a new stator frame, core and winding for unit 4.

Justification:
The stator windings at Kettle are polyester bonded mica which is prone to internal degradation as a result of thermal and electrical stresses. There has been a much higher failure rate for stator coils at Kettle than in any of our other generators installed since 1960. Analysis of the internal conditions of the insulation system is ongoing. Re-wedging units at Kettle is an opportunity to repair isolated cases of severe slot discharge, necessary to avoid deterioration. Unit 4 requires repairs due to an incident that occurred in August 2006, where a top clamping finger on the unit broke off and fell into the air gap causing extensive damage to the windings and core.

In-Service Date:
October 2022.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 75.6	$ 7.0	$ 7.3	$ 6.4	$ 6.0	$ 3.8	$ 28.0
Increase (Decrease)	-	4.1	11.1	0.2	14.1	14.8	(28.0)
Revised Forecast	$ 75.6	$ 11.1	$ 18.4	$ 6.6	$ 20.1	$ 18.6	$ -

Pointe du Bois Improvements & Upgrades

Description:
Design and build a spillway and earth fill dam to replace the existing spillway structures. Includes engineering and environmental studies, community consultation, obtaining regulatory approval, construction and de-commissioning the existing spillway.

Justification:
Pointe du Bois does not currently meet Dam Safety guidelines with respect to spillway capacity. A new spillway is required to meet these guidelines.

In-Service Date:
October 2014.

Revision:
Project estimate decreased $500.0 million to reflect scope change to exclude the construction of a new four unit powerhouse, and in-service date advanced three years from October 2017.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 818.0	$ 13.8	$ 14.8	$ 15.5	$ 91.5	$ 141.1	$ 514.5
Increase (Decrease)	(500.0)	-	-	-	(38.5)	(58.0)	(403.8)
Revised Forecast	$ 318.0	$ 13.8	$ 14.8	$ 15.5	$ 53.0	$ 83.1	$ 110.7

Pointe du Bois - Transmission

Description:
Install 17 kms of single circuit 115 kV transmission line with 795 ACSR conductor between Rover and the intersection of GT1/ST2 and the transmission right-of-way near the floodway. Install 43 kms of single circuit 115 kV transmission line with 795 ACSR conductor between Pointe du Bois and GT1/ST2 transmission line south of Lac du Bonnet. The estimate is based on the utilization of the previously vacated transmission line corridor from Pointe du Bois to GT1-ST2 transmission line south of Lac du Bonnet and from Ridgeway station to Rover station. Install a second communications link from Pointe and Slave to the System Control Center.

Justification:
To address aging infrastructure concerns with the existing 66 kV P Lines, provide adequate outlet transmission for future Pointe du Bois generating station expansion, and to integrate the Winnipeg Central System into the Manitoba Hydro System.

In-Service Date:
May 2014.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 85.9	$ 19.1	$ 12.5	$ 13.2	$ 16.4	$ 13.0	$ 2.8
Increase (Decrease)	-	(10.1)	13.8	(2.8)	4.2	0.9	0.3
Revised Forecast	$ 85.9	$ 9.0	$ 26.3	$ 10.4	$ 20.6	$ 13.9	$ 3.1

Bipole 3

Description:
Design and build a transmission line (west of Lakes Winnipegosis & Manitoba), conduct environmental impact assessments, select route, acquire property for right of way, and obtain licensing for Riel Station, a +/- 500 kV DC transmission line from proposed line paralleling site near Radisson and proposed Riel Station, and a 230 kV AC line from Riel Station to Dorsey Station (normally operated at +/- 500 kV DC).

Design and build an HVDC transmission line from Riel Converter Station (CS) to Conawapa CS; a converter station with 2000 MW of converters at Conawapa; six AC transmission lines approximately 30 kms long to connect the Conawapa converter station to the Henday converter station; and a converter station with 2000 MW of converters at Riel, including three synchronous compensators.

Justification:
Provides increased reliability to the Manitoba Hydro system due to the critical risk to the Province and the Corporation of not mitigating an Interlake (Bipole 1 and 2) corridor outage or a Dorsey station common mode outage. In normal steady state operation, it will also provide an increase in southern power at full load, due to decreased line losses (approximately 78 MW).

In-Service Date:
October 2017.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 2 247.8	$ 16.6	$ 21.4	$ 36.7	$ 113.4	$ 266.5	$ 1 774.4
Increase (Decrease)	-	-	-	-	-	-	(8.7)
Revised Forecast	$ 2 247.8	$ 16.6	$ 21.4	$ 36.7	$ 113.4	$ 266.5	$ 1 765.7

Riel 230/500 kV Station

Description:
Sectionalize Dorsey to the United States 500 kV transmission line D602F at Riel (on the southeast side of Winnipeg), and establish a station including a 230 and 500 kV ring bus, the installation of a 230/ 500 kV transformer bank, and line reactors salvaged from Dorsey 500 kV Station.

Justification:
The sectionalization of the 500 kV line allows power to be imported during a catastrophic Dorsey outage, as well as an alternate path for power export during a Dorsey transformer outage.

In-Service Date:
May 2014.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 267.6	$ 30.7	$ 68.8	$ 75.7	$ 43.5	$ 36.4	$ 4.7
Increase (Decrease)	-	5.4	(10.4)	3.9	1.6	1.8	(0.1)
Revised Forecast	$ 267.6	$ 36.1	$ 58.4	$ 79.6	$ 45.1	$ 38.2	$ 4.6

Firm Import Upgrades

Description:
Reconductor and resag transmission lines R23R, WT34, HS5 and SM26, and replace risers and current transformers for stations at Rosser, Ridgeway, Great Falls, Transcona, Mercy St., and Parkdale.

Justification:
This project will improve Manitoba Hydro's firm import capability during periods when we are expected to be energy deficient.

In-Service Date:
March 2012.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 4.8	$ 0.4	$ 2.1	$ 2.1	$ -	$ -	$ -

Revised Forecast	$ 4.8	$ 0.6	$ 2.1	$ 2.1	$ -	$ -	$ -

Dorsey - US Border New 500kV Transmission Line

Description:
Design and build a 63 KM 500 kV transmission line between Riel station and Dorsey station, and a 125 KM 500 kV transmission line between Dorsey station and the U.S. border. Acquire property for right-of-way, conduct environmental impact assessment, conduct community consultations, obtain licensing and perform environmental monitoring for all facilities.

Justification:
Manitoba Hydro has received transmission service requests for more than 750 MW of new import and export service between the U.S. and Manitoba. Term sheets have been signed for a potential 500 MW power sale to Wisconsin and a 250 MW power sale to Minnesota. These additional power sales require the construction of a new high voltage tieline between Manitoba and the U.S.

In-Service Date:
May 2018.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 204.8	$ -	$ -	$ 0.8	$ 1.8	$ 10.7	$ 191.4
Increase (Decrease)	-	-	0.5	1.1	6.4	6.9	(14.9)
Revised Forecast	$ 204.8	$ -	$ 0.5	$ 1.9	$ 8.2	$ 17.6	$ 176.5

Brandon Combustion Turbine Pipeline Upgrade

Description:
Install 11,403 meters of 12” steel transmission pressure pipeline and one control point valve assembly to assist in supplying the Brandon thermal generating station natural gas turbines.

Justification:
In order to meet Manitoba Hydro’s contractual obligation to KOCH Fertilizer Canada Ltd., as well as the firm service agreement with the Brandon thermal generating station, it is necessary to construct an additional 11,403 meters of 12” pipeline for supply to the Brandon thermal generating station natural gas turbines.

In-Service Date:
October 2009.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 5.5	$ 5.2	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	(0.1)	0.2	-	-	-	-	-
Revised Forecast	$ 5.4	$ 5.4	$ -	$ -	$ -	$ -	$ -

Demand Side Management

Description:
Design, implement and deliver incentive based PowerSmart conservation programs to reduce electricity consumption in Manitoba. When combined with savings realized to-date, total electricity savings of 915 MW and 3,271 GWh are expected to be achieved by 2025.

Justification:
The electricity Demand Side Management plan is cost effective as a resource option and is included in Manitoba Hydro's *Power Resource Plan*. Provides customers with exceptional value through the implementation of cost-effective energy conservation programs that are designed to minimize the total cost of energy services to customers, position the Corporation as a national leader in implementing cost-effective energy conservation and alternative energy programs, and by protecting the environment and promoting sustainable energy supply and service.

In-Service Date:
Ongoing.

Revision:
The increase in total expenditures is primarily due to the addition of the Industrial Emergency Preparedness Program, revisions to the Performance Optimization and BioEnergy Optimization Programs resulting in higher program costs, an increase in contingency dollars and the inclusion of another year of expenditures in 2019/20.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	NA	$ 34.6	$ 33.3	$ 31.8	$ 29.4	$ 26.0	$ 122.3
Increase (Decrease)		5.7	9.7	10.7	9.0	7.9	36.2
Revised Forecast		$ 40.3	$ 43.0	$ 42.5	$ 38.4	$ 33.9	$ 158.5

Planning Study Costs

Description:
Perform assessments, create conceptual designs and planning studies of potential supply options and associated transmission facilities. Areas of study include establishment of design parameters, structure layouts, support facilities, hydraulic model testing, exploration, data collection, environmental assessments and public input, schedules, and cost estimates.

Justification:
To plan for the orderly development of new sources of generation and related transmission facilities, and to explore supply-side efficiency improvements.

In-Service Date:
Ongoing.

Revision:
Ongoing.

	Total	2010	2011	2012	2013	2014	2015-20

Increase (Decrease)	-	14.8	-	-	-	-	-
Revised Forecast	$ 278.1	$ 14.8	$ -	$ -	$ -	$ -	$ -

CORPORATE RELATIONS:

Waterways Management Program

Description:
Waterways management at Grand Rapids and Lake Winnipeg Regulation / Churchill River Diversion.

Justification:
The Waterways Management Program (WMP) includes activities related to boat patrols, debris clearing, and supplementary works and is required to ensure ongoing safety and environmental management of waterways.

In-Service Date:
Ongoing.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	NA	$ 5.3	$ 5.5	$ -	$ -	$ -	$ -
Increase (Decrease)		-	(0.1)	-	-	-	-
Revised Forecast		$ 5.3	$ 5.4	$ -	$ -	$ -	$ -

POWER SUPPLY:

Converter Transformer Bushing Replacement

Description:
Replace converter transformer bushings with NGK bushings, and purchase spares as follows: at Dorsey replace six 230 kV AC, and six 25 kV tertiary bushings; and at Radisson/ Henday replace five 138 kV, two 150 kV, four 230 kV, and three 15 kV tertiary bushings, and purchase two 300 kV and two 450 kV spares.

Justification:
The bushing replacement program was undertaken due to failure of a 230 kV bushing in Dorsey T21 A-phase converter transformer that resulted in costly repairs to the transformer, and loss of revenue due to the outage. Also during the repair of the Dorsey T31S converter transformer in Pauwel's Canada plant, two out of two 230 kV bushings that were tested failed at far below the full test voltage. The manufacturer's expected service life is 25 years. These bushings have all been in-service more than 19 years. Replacement cost is justified when compared to transformer damage due to an in-service failure.

In-Service Date:
October 2011.

Revision:
Cost flow revision, and in-service date deferred 12 months from October 2010.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 5.9	$ 1.3	$ 1.0	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(1.2)	(0.6)	1.9	-	-	-
Revised Forecast	$ 5.9	$ 0.1	$ 0.4	$ 1.9	$ -	$ -	$ -

Bipole 1 & 2 Electrode Line Monitoring

Description:
Install a Siemens pulse-echo electrode line fault detection system on Dorsey Bipole 1 and 2, Radisson Bipole 1, and Henday Bipole 2 Electrode lines.

Justification:
There is a need for detection of open circuit, faulted, or partially down electrode line conductors based on public safety concerns, possible damage to equipment, and the security of Bipole 1 and 2.

In-Service Date:
September 2012.

Revision:
Cost flow revision, and in-service date deferred 24 months from September 2010.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 1.7	$ 1.5	$ 0.1	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(1.5)	(0.1)	1.6	-	-	-
Revised Forecast	$ 1.7	$ -	$ -	$ 1.6	$ -	$ -	$ -

Dorsey Synchronous Condenser Refurbishment

Description:
Major inspection, re-wedging and overhaul of synchronous condensers SC7Y, SC8Y, SC9Y, SC21Y, and SC23Y. Replace coolers to restore original thermal performance on SC21Y, and SC23Y. Repair corrosion problems and replace GEM80 PLC on SC7Y, SC8Y and SC9Y. Modify the 600 V transfer scheme for SC8Y, SC7Y & SC9Y.

Justification:
Synchronous condensers are required for proper operation of the HVDC system, voltage regulation of the southern AC system and to provide reactive power for power export to the United States. A major inspection and overhaul of each machine is necessary to prevent catastrophic failure, involving the rotors and rotor bolts as indicated by the failures of SC12Y in 1987 and SC11Y in 1988. The cost of repairing a failure when combined with the inability to export power will well exceed the cost of major inspection and overhaul.

In-Service Date:
March 2015.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 32.3	$ 4.5	$ 2.8	$ 3.8	$ 2.6	$ 2.7	$ 3.4
Increase (Decrease)	-	(1.5)	(0.3)	(0.2)	(0.1)	(0.1)	(0.6)
Revised Forecast	$ 32.3	$ 3.0	$ 2.5	$ 3.6	$ 2.5	$ 2.6	$ 2.8

HVDC Bipole 1 Roof Replacement

Description:
Remove existing roofs over Bipole 1, valve groups 11, 12, 13, 21, 22, and 23 at Dorsey and Radisson stations. Design, supply, install and test replacement roofs, simultaneously, and during pre-planned outages. The new roofs are to be two-ply modified bitumen membrane with R20 insulating values, and meeting FM Global fire spread and wind uplift requirements.

Justification:
The existing asphalt roofs were installed in 1970, and with maintenance have exceeded their life expectancy of 15 years. Damage to equipment due to water leaks, fire spread within a roof system, or high wind uplift and/or possible lost export sales could be very costly. Each of the six valve halls contains equipment valued at $7.0 M.

In-Service Date:
June 2009.

Revision:
In-service date advanced four months from October 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 5.9	$ 0.7	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	-	-	-	-	-	-
Revised Forecast	$ 5.9	$ 0.7	$ -	$ -	$ -	$ -	$ -

HVDC System Transformer & Reactor Fire Protection & Prevention

Description:
The supply and installation of fire protection upgrades on 33 converter transformers and eight smoothing reactors. The re-design and replacement of the deluge system on the Dorsey converter building south wall and the Henday converter building north east wall, and the construction of a fire response building in a safe location at Dorsey converter station.

Justification:
To minimize the high risk of fire spread and catastrophic damage throughout the AC and DC switchyards, and a potential transformer and revenue loss of an estimated $30 to $50 million. To provide adequate fire protection for personnel in accordance with National Fire Protection Association (NFPA) Life Safety Code 101.

In-Service Date:
December 2011.

Revision:
Cost flow revision, and in-service date deferred 14 months from October 2010.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 10.4	$ 1.1	$ 0.6	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(0.8)	0.7	0.3	-	-	-
Revised Forecast	$ 10.4	$ 0.3	$ 1.3	$ 0.3	$ -	$ -	$ -

HVDC AC Filter PCB Capacitor Replacement

Description:
Replace all Bipole 1 & 2 AC PCB filled high power capacitors at the Dorsey, Radisson, and Henday Converter Stations, with non-PCB replacement capacitors.

Justification:
Numerous PCB filled capacitor failures at HVDC converter stations have resulted in requests for outages via the System Control Centre to allow for repairs. The catastrophic failure of a capacitor in an AC filter bank of B2 would result in a pole outage. Manitoba Hydro is committed to being PCB free as outlined in corporate policy statement CP486B. The capacitors will be 27 years old and are approaching the end of their usable life.

In-Service Date:
November 2010.

Revision:
Cost flow revision, and in-service date deferred 18 months from May 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 34.5	$ 3.0	$ 4.7	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(0.6)	1.3	-	-	-	-
Revised Forecast	$ 34.5	$ 2.4	$ 6.0	$ -	$ -	$ -	$ -

HVDC Transformer Replacement Program

Description:
Maintain an inventory of eight spare converter transformers for use at Radisson, Henday and Dorsey converter stations.

Justification:
Maintenance of an inventory of spare converter transformers will limit outage durations and outage costs in the event of converter transformer failures.

In-Service Date:
October 2013.

Revision:
Cost flow revision, and in-service date deferred 19 months from March 2012.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 105.7	$ 4.5	$ 10.0	$ (0.2)	$ 0.3	$ -	$ -
Increase (Decrease)	-	(3.5)	(8.9)	7.5	5.0	1.1	-
Revised Forecast	$ 105.7	$ 1.0	$ 1.1	$ 7.3	$ 5.3	$ 1.1	$ -

Dorsey 230 kV Relay Building Upgrade

Description:
Upgrade the 230 kV relay building at Dorsey and provide mobile protection and control trailers.

Justification:
Upgrades to the building will reduce the risk of damage from weather related perils and limit the consequence of a Bipole failure due to fire related perils. Mobile protection and control trailers will facilitate the quick restoration of service in the case of a catastrophic event to this or other relay buildings.

In-Service Date:
March 2016.

Revision:
Cost flow revision, and in-service date deferred seven months from August 2015.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 73.8	$ 2.8	$ 3.5	$ 1.7	$ 15.8	$ 32.9	$ 15.8
Increase (Decrease)	-	(1.7)	(1.6)	2.3	0.6	(0.8)	1.1
Revised Forecast	$ 73.8	$ 1.1	$ 1.9	$ 4.0	$ 16.4	$ 32.1	$ 16.9

HVDC Stations Ground Grid Refurbishment

Description:
Upgrade the existing ground grid systems at Dorsey, Radisson and Henday Stations.

Justification:
These upgrades improve the safety of employees and contractors working in and around the HVDC converter stations, by ensuring that touch and step potential are within safe levels.

In-Service Date:
October 2013.

Revision:
Cost flow revision, and in-service date deferred seven months from March 2013.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 4.3	$ 0.4	$ 0.3	$ 0.4	$ 0.5	$ -	$ -
Increase (Decrease)	-	0.2	0.2	0.2	0.1	-	-
Revised Forecast	$ 4.3	$ 0.6	$ 0.5	$ 0.6	$ 0.6	$ -	$ -

HVDC Bipole 2 230 kV HLR Circuit Breaker Replacement

Description:
Replace the existing 34 HLR operating mechanisms with new operating mechanisms, evaluate five HLR breaker and drive mechanisms, purchase one spare HLR operating mechanism, rebuild 126 AHMA drives, purchase six AHMA drives, remove 203 600V arc chutes and rebuild the associated 600V breakers, and the replacement of all 600V breaker hydraulic overloads with electronic overloads.

Justification:
System reliability will be improved. BLG1002A breaker operating mechanisms are designed to handle the frequent switching experienced by these 16 breakers, reduce repair and maintenance frequency, and reduce the risk of failure. A breaker failure results in a bus outage and single contingency of the 230 kV bus. There is a Bipole outage risk, if bus B1 or B2 at Dorsey is out of service for any reason.

In-Service Date:
December 2013.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 9.4	$ 1.3	$ 0.8	$ 0.3	$ -	$ -	$ -
Increase (Decrease)	-	1.4	(0.4)	(0.3)	-	-	-
Revised Forecast	$ 9.4	$ 2.7	$ 0.4	$ -	$ -	$ -	$ -

HVDC Bipole 1 Pole Differential Protection

Description:
Prepare an engineering report to determine all possible options, scope of work, cost analysis, and detailed cost estimate. Implement the preferred option at both Dorsey and Radisson stations.

Justification:
Upgrading Bipole 1 pole differential protection is necessary to eliminate healthy pole blocks, thus reducing outages and increasing availability.

In-Service Date:
December 2011.

Revision:
Cost flow revision, and in-service date deferred 24 months from December 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 3.3	$ 3.3	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(3.3)	1.0	2.3	-	-	-
Revised Forecast	$ 3.3	$ -	$ 1.0	$ 2.3	$ -	$ -	$ -

HVDC Bipole 1 By-Pass Vacuum Switch Removal

Description:
Remove the existing By-Pass Vacuum Switch (BPVS) and By-Pass Switch (BPS) and replace both with a single BPS at Dorsey and Radisson stations (Bipole 1 valve halls). In addition, Radisson will have its AC line switch (ACCQ) removed.

Justification:
The equipment is nearing the end of its service life and requires substantial maintenance. By-pass vacuum switches were part of the replaced mercury arc valves switching scheme. The new thyristor valves may be more reliably served by other types of switches, thus reducing the forced outage rate.

In-Service Date:
March 2014.

Revision:
Cost flow revision, and in-service date deferred one year from March 2013.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 20.4	$ 4.7	$ 5.4	$ 4.4	$ 5.8	$ -	$ -
Increase (Decrease)	-	(4.2)	(0.8)	3.8	(0.2)	1.2	-
Revised Forecast	$ 20.4	$ 0.5	$ 4.6	$ 8.2	$ 5.6	$ 1.2	$ -

HVDC Bipole 2 Refrigerant Condenser Replacement

Description:
Remove and replace existing air conditioning systems in the Bipole 2 valve halls, maintenance blocks and administration areas at both Dorsey and Henday converter stations.

Justification:
The present systems are nearing the end of their service life. Maintenance is increasing, along with the likelihood of costly valve outages. In addition, the present systems contain R-22 (an ozone depleting substance).

In-Service Date:
April 2013.

Revision:
Cost flow revision, and in-service date deferred one year from April 2012.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 11.0	$ -	$ 2.9	$ 7.2	$ 0.9	$ -	$ -
Increase (Decrease)	-	-	(2.9)	(4.4)	6.3	1.0	-
Revised Forecast	$ 11.0	$ -	$ -	$ 2.8	$ 7.2	$ 1.0	$ -

HVDC Bipole 1 Smoothing Reactor Replacement

Description:
Remove existing oil-filled Bipole 1 smoothing reactors at Dorsey and Radisson, and replace with new air core reactors.

Justification:
Existing Bipole 1 smoothing reactors are approaching the end of their service life. Replacement will ensure continued availability and reliable operation of the HVDC system. Removal of oil–filled reactors will reduce the risk of oil spills and fires within the work place.

In-Service Date:
October 2018.

Revision:
Cost flow revision, and in-service date deferred six years from October 2012.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 31.8	$ 3.1	$ 10.5	$ 12.8	$ 5.1	$ -	$ -
Increase (Decrease)	-	(3.1)	(10.4)	(12.7)	(5.0)	4.0	27.7
Revised Forecast	$ 31.8	$ -	$ 0.1	$ 0.1	$ 0.1	$ 4.0	$ 27.7

HVDC Bipole 1 Converter Station, P1 & P2 Battery Bank Separation

Description:
Separate Pole 1 & Pole 2 battery banks at Dorsey and Radisson converter stations. Upgrade the battery banks and charger ratings to comply with current Manitoba Hydro design criteria.

Justification:
Pole 1 & Pole 2 battery banks have to be physically separated in order to provide a reliable first grade supply to the HVDC controls and protection and communication system.

In-Service Date:
February 2013.

Revision:
Cost flow revision, and in-service date deferred one year from February 2012.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 3.2	$ -	$ 1.0	$ 2.2	$ -	$ -	$ -
Increase (Decrease)	-	-	(1.0)	(1.2)	2.2	-	-
Revised Forecast	$ 3.2	$ -	$ -	$ 1.0	$ 2.2	$ -	$ -

HVDC Bipole 1 DCCT Transductor Replacement

Description:
Replace existing oil-filled DC transductors with optical transductors at Dorsey and Radisson stations.

Justification:
Existing BP1 DCCT transductors are reaching the end of service life and spares are no longer available. Failure of a transductor to transmit a required signal to protective and controls equipment at Dorsey and Radisson stations can cause a lengthy pole outage. A fire in the existing oil-filled transductors could result in irreparable damage to adjacent equipment and a lengthy pole outage. Replacement will contribute to reliable operation of the HVDC system. Removal of the oil-filled transductors will reduce the risk of oil spills and fires within the workplace.

In-Service Date:
October 2016.

Revision:
Cost flow revision, and in-service date deferred two years from October 2014.

	Total	2010	2011	2012	2013	2014	2015-20

Increase (Decrease)	-	(2.5)	(0.6)	(0.7)	(0.5)	2.1	2.8
Revised Forecast	$ 11.7	$ -	$ 0.6	$ 2.8	$ 0.8	$ 3.9	$ 3.5

HVDC BP1 & BP2 DC Converter Transformer Bushing Replacements

Description:
Remove and replace transformer bushings on all converter transformers over 25 years old.

Justification:
Bushings on converter transformers over 25 years old are reaching the end of their service life. A bushing failure while in-service would cause a costly valve group outage to repair or replace the bushing and could cause irreparable damage to a converter transformer.

In-Service Date:
March 2015.

Revision:
Cost flow revision, and in-service date deferred 18 months from September 2013.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 8.7	$ 0.5	$ 1.0	$ 1.6	$ 5.1	$ 0.5	$ -
Increase (Decrease)	-	(0.5)	(1.0)	(1.1)	(4.1)	1.2	5.4
Revised Forecast	$ 8.7	$ -	$ -	$ 0.5	$ 1.0	$ 1.7	$ 5.4

HVDC Bipole 2 Valve Hall Wall Bushing Replacements

Description:
Replace all oil-filled wall bushings in the Bipole 2 valve halls with new solid core bushings or SF6 filled bushings.

Justification:
Existing wall bushings in the Bipole 2 valve halls are over 20 years old and are reaching the end of their service life. The risk of bushing failure and fire in a valve hall increases as the bushings age. Replacing the bushings will ensure reliable operation of the valve group well into the future, and provide a safer working environment for employees at the converter stations.

In-Service Date:
June 2015.

Revision:
Cost flow revision, and in-service date deferred two years from June 2013.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 19.2	$ 3.4	$ 4.6	$ 4.7	$ 4.8	$ 1.8	$ -
Increase (Decrease)	-	(3.4)	(4.5)	(1.4)	(0.3)	2.8	6.7
Revised Forecast	$ 19.2	$ -	$ 0.1	$ 3.3	$ 4.5	$ 4.6	$ 6.7

HVDC Bipole 1 CQ Disconnect Replacement

Description:
Replace the existing Radisson and Dorsey DC disconnects, and Dorsey AC disconnects with new disconnects.

Justification:
Major failures of CQ disconnects cause costly pole outages, and these disconnects are reaching the end of their service life. They have been in-service for 36 years, their failure rate is increasing, and spare parts are no longer available.

In-Service Date:
April 2014.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 5.2	$ -	$ 1.2	$ 1.6	$ 0.9	$ 1.1	$ 0.3
Increase (Decrease)	-	-	(1.2)	(0.5)	0.6	(0.2)	1.3
Revised Forecast	$ 5.2	$ -	$ -	$ 1.1	$ 1.5	$ 0.9	$ 1.6

HVDC Bipole 2 Thyristor Module Cooling Refurbishment

Description:
Refurbish 1 566 thyristor module cooling components in Bipole 2 by replacing the manifolds, connectors and cooling tubes.

Justification:
The cooling components are reaching the end of their life, and are starting to leak, resulting in forced outages. Refurbishing the module cooling components will improve the reliability of the cooling system and extend its life until the replacement of the Bipole 2 system equipment, which is in approximately 10 - 15 years.

In-Service Date:
March 2012.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 4.7	$ 1.8	$ 1.8	$ 0.8	$ -	$ -	$ -
Increase (Decrease)	-	-	(0.1)	-	-	-	-
Revised Forecast	$ 4.7	$ 1.8	$ 1.7	$ 0.8	$ -	$ -	$ -

HVDC Bipole 2 Smoothing Reactor Replacement

Description:
Replace four existing oil-filled Bipole 2 smoothing reactors with air core smoothing reactors at Dorsey and Henday.

Justification:
The smoothing reactors have already exceeded their estimated useful life of 25 years. Each DC line fault and AC system fault in the southern AC system results in sudden current surges in the smoothing reactors resulting in physical shaking and contraction of the windings. As a result, the blockings in the winding become loose and have to be retightened. The reactors have been subject to these faults for many years. When the reactors do eventually fail, the units will be replaced with air core reactors. Replacing them with an air core reactor now would alleviate the environmental and fire concerns, and provide a reliable system for the future and reduce maintenance and protection systems requirements.

In-Service Date:
September 2013.

Revision:
Cost flow revision, and in-service date advanced one year from September 2014.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 17.1	$ -	$ -	$ 7.0	$ 6.5	$ 3.0	$ 0.6
Increase (Decrease)	-	0.8	3.5	(3.8)	(0.8)	0.8	(0.6)
Revised Forecast	$ 17.1	$ 0.8	$ 3.5	$ 3.2	$ 5.7	$ 3.8	$ -

HVDC Bipole 1 Transformer Marshalling Kiosk Replacement

Description:
Replace nine Bipole 1 transformer marshalling kiosks with insulated Programmable Logic Controllers (PLC) monitoring marshalling kiosks, and upgrade 19 control boxes at the transformer with a quick disconnect system.

Justification:
The new control boxes will remove the 600V from the controls and monitoring section of the panel which will eliminate the present safety concerns that site workers face while performing maintenance or trouble shooting.

In-Service Date:
November 2014

Revision:
New item.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ -	$ -	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	6.8	1.0	1.0	1.6	1.6	1.1	0.5
Revised Forecast	$ 6.8	$ 1.0	$ 1.0	$ 1.6	$ 1.6	$ 1.1	$ 0.5

Pine Falls Rehabilitation

Description:
Rehabilitation, replacement of and addition to various electrical and mechanical equipment and systems such as spillway mechanical components, station service upgrade, station lighting, 11 kV cable replacement, spillway electrical distribution, water system, air system, transformer lightning arrestors, and station drawings. Replace unit 1 and 2 turbine runners with more efficient new design runners, rebuild existing servomotors for increased wicket gate opening allowing more discharge, and rewind the generator stators utilizing modern insulating materials. Conduct a model test and up-rate study. Replace potential transformers, synchronizers, annunciators, generator breakers, excitation and governor systems, step-up transformers and electrical back-up systems.

Justification:
Assessment of the electrical and mechanical systems has identified concerns in terms of obsolete equipment, safety, fire risk and adaptability to present day operating conditions and standards. Upgrading is necessary to ensure reliable safe and economical operation. Pine Falls consistently spills more water than the other Winnipeg River plants. Additional generation can be obtained (approximately 17%) with increased discharge capability. Tests have confirmed that the two stator windings are in danger of failure at any time.

In-Service Date:
March 2015.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 56.2	$ 4.6	$ 24.5	$ 5.2	$ 3.8	$ 3.2	$ 6.6
Increase (Decrease)	-	(1.8)	(20.3)	12.2	8.4	(1.1)	4.3
Revised Forecast	$ 56.2	$ 2.8	$ 4.2	$ 17.4	$ 12.2	$ 2.1	$ 10.9

Jenpeg Unit Overhauls

Description:
Major overhaul of all generating units (1-6) to inspect, repair, modify, and replace components of the turbine/ generator. Areas of concern include journal bearings, thrust bearings, turbine seals, servo motors, wicket gate seals and bushings, waterhead and oil head, stator and rotor, and auxiliary systems.

Justification:
A complete overhaul is required to ensure reliable operation of the units when maximum power requirements on the system are essential.

In-Service Date:
December 2021.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 128.1	$ -	$ -	$ -	$ -	$ -	$ 49.2
Increase (Decrease)	-	-	-	-	-	-	23.9
Revised Forecast	$ 128.1	$ -	$ -	$ -	$ -	$ -	$ 73.1

Power Supply Dam Safety Upgrades

Description:
Perform necessary engineering design and remedial construction to upgrade generating stations to present day dam safety standards: 1) Kettle generating station – upgrade main and saddle dams for freeboard; 2) Kelsey generating station – armour plating at spillway rollways, erection of heated hoist housing, insulating of spillway gates, upgrading of dikes, upgrading of spillway feeders and electrical systems at the spillway, and upgrading of the station service transformers due to increased loading; and 3) southern generating stations - capital works identified in the dam safety certification process or identified through observation and discussion with staff.

Justification:
Work is required to correct deficiencies to all the plants, in order to operate in a safe and reliable manner.

In-Service Date:
March 2016.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 34.0	$ 3.5	$ 1.2	$ 1.2	$ 1.2	$ 1.3	$ 3.2
Increase (Decrease)	-	6.2	0.5	(1.2)	(1.2)	(1.3)	(3.2)
Revised Forecast	$ 34.0	$ 9.7	$ 1.7	$ -	$ -	$ -	$ -

Winnipeg River Riverbank Protection Program

Description:
Placement of rock protection and construction of slope stabilization to reduce the erosion of riverbanks along the Winnipeg River. The work includes inspection, design, mapping, land acquisition, and remedial construction at priority locations along reaches of the Winnipeg River affected by Manitoba Hydro hydraulic operations.

Justification:
Provision of riverbank protection and stabilization work along the Winnipeg River between Seven Sisters forebay and Manitou rapids to protect private property from erosion partially due to hydraulic operations.

In-Service Date:
March 2017.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 19.7	$ 1.1	$ 1.2	$ 1.2	$ 1.2	$ 1.3	$ 4.0
Increase (Decrease)	-	0.2	-	-	0.1	-	0.1
Revised Forecast	$ 19.7	$ 1.3	$ 1.2	$ 1.2	$ 1.3	$ 1.3	$ 4.1

Power Supply Hydraulic Controls

Description:
Install an optimization system to run all 39 units at Kelsey, Kettle, Long Spruce, and Limestone at their most efficient gate opening. Install a Decision Support System (DSS) to provide accurate short-term Hydro scheduling (water resource management) and feedback information. Install required automation, remote control, and protective devices for unmanned operation.

Justification:
By increasing unit efficiency, the Corporation can reduce or delay the need for capital expenditures for new plant, increase export net revenues, improve financial strength, and protect the environment.

In-Service Date:
March 2020.

Revision:
Cost flow revision, and in-sevice date deferred 63 months from December 2014.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 16.0	$ 1.8	$ 0.9	$ 2.5	$ 2.4	$ 0.9	$ 1.0
Increase (Decrease)	-	1.3	1.0	(1.3)	(2.4)	(0.9)	4.6
Revised Forecast	$ 16.0	$ 3.1	$ 1.9	$ 1.2	$ -	$ -	$ 5.6

Slave Falls Rehabilitation

Description:
Perform major overhaul for all eight units at Slave Falls Generating Station, including spillway improvements/ replacements, excitation upgrades, and the addition of a Unit Control and Monitoring System (UCMS) Framework.

Justification:
Many safety, reliability, environmental, efficiency, operational & dam safety issues have been identified relating to the Slave Falls infrastructure. Extensive repairs, modifications and/or replacements will be required to ensure the serviceability of the plant and spillway infrastructure. Economics of this work may suggest that a new spillway be constructed to replace existing spill infrastructure. Current operating procedures include ice load reduction activites at the spilling structures to ensure structural stability. A dam safety concern has been identified with respect to the minimal remote spilling capability at Slave Falls.

In-Service Date:
December 2017.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 198.3	$ 13.7	$ 10.4	$ 8.9	$ 23.6	$ 29.9	$ 96.5
Increase (Decrease)	-	(0.7)	(6.4)	(7.8)	(7.3)	(18.1)	44.6
Revised Forecast	$ 198.3	$ 13.0	$ 4.0	$ 1.1	$ 16.3	$ 11.8	$ 141.1

Great Falls Unit 4 Overhaul

Description:
Major overhaul to generating Unit 4 including generator rewind, turbine re-runnering, new water passage embedded components, one 3-phase unit transformer, and modernization of components.

Justification:
The re-runnering and major overhaul will provide an opportunity to upgrade/modernize the unit while taking advantage of an already planned outage for the intake gates. The re-runnering will add both capacity and efficiency. The existing transformer is in poor condition and water passage components are starting to fail. The overhaul will increase reliability and extend the asset life by 40 to 50 years.

In-Service Date:
December 2011.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 19.7	$ 4.1	$ 8.1	$ 5.4	$ -	$ -	$ -
Increase (Decrease)	-	(1.1)	(1.1)	2.4	-	-	-
Revised Forecast	$ 19.7	$ 3.0	$ 7.0	$ 7.8	$ -	$ -	$ -

Great Falls 115 kV Indoor Station Safety Improvements

Description:
Improve electrical safety clearance in the 115 kV switching gallery by replacing the air blast breakers with separate current transformers (CTs) with smaller dead tank SF_6 breakers with integral CTs, raise potential transformer (PT) equipment, install Lexan insulating panels to improve the separation between buses, improve grounding provisions, and add safety screens around disconnects.

Justification:
The indoor switching gallery has many instances of electrical clearances that are less than the absolute minimum limit of approach, and do not meet the minimum standard outlined in the Manitoba Hydro safety book.

In-Service Date:
April 2009.

Revision:
Cost flow revision, and in-service date advanced seven months from November 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 11.6	$ 0.9	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.7	-	-	-	-	-
Revised Forecast	$ 11.6	$ 1.6	$ -	$ -	$ -	$ -	$ -

Generation South Transformer Refurbish & Spares

Description:
Purchase a spare generator step-up transformer and refurbish the existing generator step-up transformers at Jenpeg GS; purchase a spare three phase generator step-up transformer at Pine Falls GS; refurbish ten generator step-up transformers at Grand Rapids GS; and purchase two 3-phase generator step-up transformers and install one in Bank 6 at Great Falls GS.

Justification:
To minimize the occurrence and duration of transformer-related forced outages, it is imperative that spare transformers are available.

In-Service Date:
March 2017.

Revision:
Cost flow revision, and in-service date deferred two years from March 2015.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 21.0	$ 2.9	$ 5.3	$ 4.5	$ 3.1	$ 2.6	$ 1.6
Increase (Decrease)	-	(2.9)	(3.8)	(1.4)	2.2	1.8	5.0
Revised Forecast	$ 21.0	$ -	$ 1.5	$ 3.1	$ 5.3	$ 4.4	$ 6.6

Water Licenses & Renewals

Description:
Conduct hydraulic studies, geotechnical assessments, property status and severance line determinations, mapping, license documentation, environmental reviews, and community informational sessions necessary to secure license finalization and/or renewals for the Corporation's hydraulic plants.

Justification:
All hydraulic generating facilities must be authorized under Water Power licenses and these licenses need to be clearly in force to significantly reduce risk exposure, maintain operating flexibility, maximize export revenues, and contribute to financial strength.

In-Service Date:
May 2016.

Revision:
Cost flow revision, and in-service date deferred two months from March 2016.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 40.8	$ 5.1	$ 5.6	$ 4.9	$ 4.8	$ 4.6	$ 9.5
Increase (Decrease)	-	(0.7)	0.4	1.1	0.9	1.3	(1.4)
Revised Forecast	$ 40.8	$ 4.4	$ 6.0	$ 6.0	$ 5.7	$ 5.9	$ 8.1

Generation South PCB Regulation Compliance

Description:
Replace equipment identified as containing polychlorinated biphenyl (PCB) content > 50 ppm at generation south generating stations.

Justification:
Required to comply with Federal legislation regarding the replacement of equipment in non-sensitive areas with PCB content > 50 ppm.

In-Service Date:
March 2015.

Revision:
Cost flow revision, and in-service date deferred three months from December 2014.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 4.7	$ 2.0	$ 1.6	$ 0.4	$ 0.4	$ 0.2	$ -
Increase (Decrease)	-	(1.8)	(1.3)	(0.3)	(0.3)	-	3.8
Revised Forecast	$ 4.7	$ 0.2	$ 0.3	$ 0.1	$ 0.1	$ 0.2	$ 3.8

Kettle Transformer Overhaul Program

Description:
Purchase two spare transformers, one for the Kettle GS and one for the Long Spruce/Limestone generating stations. Subsequent to receiving the new transformers, the remaining 12 step-up transformers will be overhauled.

Justification:
Kettle step-up transformers have been in operation for 37 years, with a life expectancy of between 30 and 50 years. During this time frame there have been more transformer winding failures at the Kettle GS than anywhere else in Manitoba Hydro.

In-Service Date:
April 2014.

Revision:
Cost flow revision, and in-service date advanced two years from April 2016.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 35.6	$ 3.3	$ 3.8	$ 4.6	$ 4.9	$ 5.7	$ 12.4
Increase (Decrease)	-	(1.7)	2.8	1.9	1.7	1.1	(5.0)
Revised Forecast	$ 35.6	$ 1.6	$ 6.6	$ 6.5	$ 6.6	$ 6.8	$ 7.4

Generation South Breaker Replacements

Description:
Remove the four existing 115 kV current transformers and breakers at McArthur Falls GS, and replace with new 115 kV breakers with internal current transformers, and replace the fourteen 115 kV breakers at the Pine Falls GS.

Justification:
The breakers at both stations require replacing as spare parts are no longer available. In addition, the breakers at both stations are PCB contaminated. Proposed federal PCB regulation currently states that all equipment with a concentration >50ppm must be removed from service by December 31, 2014.

In-Service Date:
October 2013.

Revision:
Cost flow revision, and in-service date deferred seven months from March 2013.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 9.4	$ 2.5	$ 0.9	$ 2.8	$ 1.6	$ -	$ -
Increase (Decrease)	-	(0.9)	2.2	(0.6)	0.4	0.4	-
Revised Forecast	$ 9.4	$ 1.6	$ 3.1	$ 2.2	$ 2.0	$ 0.4	$ -

Seven Sisters Upgrades

Description:
Rewind and rehabilitate Seven Sisters Unit 5 to maintain station MW output and prevent a high probability stator in-service failure through a planned generator rewind outage. Replace and upgrade generator and transformer protection on units 1, 2, 3, 4 and 6 to a redundant multifunction system with breaker fail protection, transient fault recording, and metering replacement.

Justification:
Seven Sisters Unit 5 stator winding has been identified as a candidate for potential failure through electrical condition assessment. The stator condition has deteriorated such that normal operation now contributes to accelerating the stator failure. In addition, transmission line events (115 kV faults) have been identified which would cause generator damage for the station. The existing protection system is incapable of detecting and interrupting these specific events, and is of a similar vintage to the replaced Kelsey electro-mechanical system, but with a longer operating history. Original electro-mechanical relay manufacturers no longer exist and replacement parts are currently salvaged from other recently upgraded generating stations.

In-Service Date:
August 2012.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 9.5	$ 3.5	$ 2.5	$ 1.2	$ 1.0	$ -	$ -
Increase (Decrease)	-	(1.7)	2.8	-	-	-	-
Revised Forecast	$ 9.5	$ 1.8	$ 5.3	$ 1.2	$ 1.0	$ -	$ -

Generation South Excitation Upgrades

Description:
Implement a generator excitation system replacement program to phase out unsupported and obsolete equipment at the Great Falls, Grand Rapids and McArthur Falls generating stations.

Justification:
Original excitation systems on the Winnipeg River have a frequent failure rate which has negative effects on export revenue. Spare parts for the excitation systems at these GSs are no longer available, and the salvage inventory from Seven Sisters GS and Laurie River GS are exhausted. The current systems cannot be tuned due to physical wear and have failing rotating exciter insulation systems, which will renderl the generators inoperable in the event of an exciter failure.

In-Service Date:
February 2019.

Revision:
Cost flow revision, and in-service date deferred 34 months from April 2016.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 18.3	$ -	$ 2.0	$ 3.2	$ 3.9	$ 3.3	$ 6.0
Increase (Decrease)	-	-	-	(2.2)	(2.8)	(1.6)	6.5
Revised Forecast	$ 18.3	$ -	$ 2.0	$ 1.0	$ 1.1	$ 1.7	$ 12.5

Brandon Unit 5 License Review

Description:
Renewal of Brandon Generating Station Unit 5 (Manitoba Environment Act license) is required for continuing operation. License renewal requires minor plant refurbishment. The timing and extent of additional future environmental regulatory changes is uncertain. The base case conservatively assumes that environmental controls must be installed. Should the need for additional controls be identified during the licensing process or subsequently thereafter, the economic viability of such controls will be assessed accordingly. Per the Manitoba Climate Change and Emissions Reductions Act (Bill 15), Manitoba Hydro must not use coal to generate power after December 31, 2009, except to support emergency operations.

Justification:
Unit 5 plays an important role in Manitoba Hydro's system, contributing economic generation and enhancing system reliability.

In-Service Date:
March 2012.

Revision:
Cost flow revision, and in-service date deferred one year from March 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 18.7	$ 6.2	$ 7.7	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(5.9)	(5.2)	11.1	-	-	-
Revised Forecast	$ 18.7	$ 0.3	$ 2.5	$ 11.1	$ -	$ -	$ -

Selkirk Enhancements

Description:
Perform environmental enhancements in accordance with the revised license terms and conditions approved by the Province of Manitoba on April 30, 2008. The approval was based on continuing operation of the once-through cooling system with modifications to the cooling water intake fish screen, lube oil cooling system and condenser re-tubing.

Justification:
Provides assurance that the station will be able to operate as planned with the addition of the cooling tower, and provides long-term southern system reliability benefits.

In-Service Date:
August 2010.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 14.2	$ 4.9	$ 2.8	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.9	2.4	-	-	-	-
Revised Forecast	$ 14.2	$ 5.8	$ 5.2	$ -	$ -	$ -	$ -

Laurie River/CRD Communications and Annunciation Upgrades

Description:
Upgrade the communications infrastructure and replace the annunciation systems with Programmable Logic Controller (PLC) based Unit Control Monitoring Systems (UCMS) at Laurie River, Missi Falls and Notigi.

Justification:
Updated communications infrastructure and annunciation systems will provide more accurate water level information from the Churchill River Diversion allowing Manitoba Hydro to optimize water flows through the lower Nelson River Generating Stations. In addition, the maintenance costs will be reduced significantly with the implementation of the new system.

In-Service Date:
August 2012.

Revision:
New item.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ -	$ -	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	4.8	0.2	3.5	-	1.1	-	-
Revised Forecast	$ 4.8	$ 0.2	$ 3.5	$ -	$ 1.1	$ -	$ -

Notigi Marine Vessel Replacement & Infrastructure Improvements

Description:
Replace the existing Notigi marine vessels with one self-propelled unit and upgrade the vessel tramway to prevent damaging vessels when removing them from the water.

Justification:
The marine vessels are over 30 years old and in need of numerous repairs and upgrades, including hull repairs which are very difficult to weld repair. In addition, changes in Canadian Coast Guard regulations will require stability tests, and it is expected that at least one of the vessels will not pass this test, and will be deemed unsuitable for operation.

In-Service Date:
June 2011.

Revision:
New Item.

	Total	2010	2011	2012	2013	2014	2015-20

Revised Forecast	$ 2.6	$ -	$ 1.3	$ 1.3	$ -	$ -	$ -

Fire Protection Projects - HVDC

Description:
The replacement of the existing Incipient Fire Detection (IFD) panels at all HVDC Stations with new Fenwal Fire Detection Systems, the replacement of the Radisson station building fire piping and fire pumps, and the installation of a fire water backup system at Henday Station.

Justification:
More than half of the existing IFD panels have failed. They are costly to maintain and parts are difficult to obtain. The backup fire protection does not meet the fire code. The Radisson fire piping and pumps are inadequate and have no water left to fight fire spread should a transformer fail and deluge be activated. The current Henday fire water backup system is inadequate and runs dry up to 30 minutes prior to the fire department's arrival at site. New tanks will ensure fire containment and prevent spreading until the fire department's arrival.

In-Service Date:
October 2012.

Revision:
Cost flow revision, and in-service date deferred 23 months from November 2010.

	Total	2010	2011	2012	2013	2014	2015-20

Increase (Decrease)	-	(2.0)	0.4	1.6	1.7	-	-
Revised Forecast	$ 5.2	$ 0.5	$ 0.4	$ 1.6	$ 1.7	$ -	$ -

Halon Replacement Project

Description:
Remove and replace the existing Halon fire protection systems with approved state-of-the-art alternative technologies such as water and gaseous based systems.

Justification:
Replacing the existing Halon fire protection systems with approved alternative technologies improves the HVDC, hydraulic, and diesel systems availability, minimizes the risk of extremely expensive outage and repair costs, and minimizes lost revenue. Halon replacement is becoming a mandatory requirement through Federal and Provincial environmental regulations and legislation. National Fire Protection Association (NFPA) Life Safety Code 101 requires the adequate provision of fire protection where, in addition to equipment, the human element is also involved.

In-Service Date:
March 2011.

Revision:
Cost flow revision, and in-service date deferred nine months from June 2010.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 42.5	$ 19.2	$ 11.0	$ 0.4	$ -	$ -	$ -
Increase (Decrease)	-	(4.6)	2.1	8.7	-	-	-
Revised Forecast	$ 42.5	$ 14.6	$ 13.1	$ 9.1	$ -	$ -	$ -

Power Supply Fall Protection Program

Description:
Implement fall protection for Power Supply stations (excludes switchyards), including four diesel sites, in compliance with Provincial Regulation 189/85, under Workplace Safety and Health Act W210.

Justification:
Provincial regulation requires employers to establish fall protection systems for work performed where there is danger of falling more than 2.5 meters into unprotected operating machinery or in/onto hazardous substances and objects.

In-Service Date:
March 2009.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 13.5	$ -	$ -	$ -	$ -	$ -	$ -

Revised Forecast	$ 13.5	$ 0.2	$ -	$ -	$ -	$ -	$ -

Oil Containment – Power Supply

Description:
Modifications and/or additions are required to prevent and contain oil spills: 1) *southern and northern hydraulic generating stations*: install oil/ water separators, modify drainage systems, and upgrade sump, fuel storage facilities and dyking systems; 2) *converter stations*: install an oil containment system to collect and recover any oil spilled within the station and encapsulate oil filled transformers/smoothing reactors at the three HVDC stations to stop gasket leaks.

Justification:
Previous experience with oil spills requires the Corporation to demonstrate due diligence with respect to containing and minimizing the potential for any further occurances.

In-Service Date:
May 2017.

Revision:
Cost flow revision, and in-service date deferred one year from May 2016.

	Total	2010	2011	2012	2013	2014	2015-20

Grand Rapids Townsite House Renovations

Description:
Renovate 26 homes within the Grand Rapids Hybord Townsite, over a five year construction period.

Justification:
Providing adequate and modern housing is critical to attracting employees to fill job vacancies at Grand Rapids.

In-Service Date:
March 2015.

Revision:
New item.

	Total	2010	2011	2012	2013	2014	2015-20

Grand Rapids Fish Hatchery

Description:
Rehabilitate the main hatchery building, the aeration building, the east and west pump houses, shops building, the exterior tanks and grounds, and replace the water meter.

Justification:
Provide for the benefits of environmental protection, employee safety and the modernization of obsolete and high maintenance assets.

In-Service Date:
March 2012.

Revision:
New item.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ -	$ -	$ -	$ -	$ -	$ -	$ -

Generation Townsite Infrastructure

Description:
Gillam townsite: 1) interior and exterior retrofit of 66 corporate houses; 2) replace 40 doublewide trailers on basements with ready-to-move (RTM) homes and construct 32 new housing units over eight years; and 3) construct a new shopping centre (possibly in partnership).

Justification:
Gillam infrastructure evaluation lists the following as substandard: water quality, sewage treatment, water and sewer lines, asphalt repairs, recreation facility, trailer park improvements, and town office building renovations.

In-Service Date:
March 2012.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 52.1	$ 9.6	$ 5.3	$ 4.5	$ -	$ -	$ -

Site Remediation of Contaminated Corporate Facilities

Description:
Conduct geotechnical investigation of the various contaminated corporate facilities and remediate contaminated areas to environmentally acceptable limits.

Justification:
Environmental concerns and/or regulations require that corporate facilities be investigated and remediated to restore them to a level which permits unrestricted use of the site.

In-Service Date:
March 2013.

Revision:
Additional funds allocated for the clean-up of construction era debris and remediation of the South Bay Channel.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 30.9	$ 0.7	$ 0.5	$ 0.4	$ 0.3	$ -	$ -

High Voltage Test Facility

Description:
Build a new high voltage test facility at 1840 Chevrier Blvd., including a high voltage hall with rail access, supporting labs, shop, storage, and office and receiving space.

Justification:
This facility will enable Manitoba Hydro to adequately meet present industry standards (CAN/CSA C88.1-96, CAN3-C13-M83, CAN/CSA C225-00, and the recently adopted IEC 619361-1) for the testing of all bushings, instrument transformers and aerial lift devices, while improving the efficiency and safety of our insulation testing practices. Testing extra high voltage equipment to industry standards is the optimal way to avoid costly forced outages and life threatening and environmentally damaging failures, safeguard the reliability of our power supply, and enhance safety during live line work.

In-Service Date:
June 2011.

Revision:
Cost flow revision, and in-service date deferred three months from March 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 26.9	$ 15.9	$ 5.7	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(5.3)	7.8	-	-	-	-
Revised Forecast	$ 26.9	$ 10.6	$ 13.5	$ -	$ -	$ -	$ -

Power Supply Security Installations / Upgrades

Description:
Install, upgrade and enhance security systems, such as fencing, close circuit TV, and card access systems at Power Supply HVDC and generating stations. Implement of a comprehensive "Public Water Safety Around Dams" program, which is generally compliant with the draft Canadian Dam Association (CDA) 2007 technical bulletin for Public Safety and Security Around Dams.

Justification:
The scope of work is intended to raise the security standards of the stations to the levels outlined in the Security Readiness Report and to be compliant with NERC standards.

In-Service Date:
March 2016.

Revision:
Increased project scope to include the implementation of a comprehensive "Public Water Safety Around Dams" program. In-service date deferred 62 months from January 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 36.3	$ 21.4	$ 7.4	$ -	$ -	$ -	$ -
Increase (Decrease)	6.9	(11.7)	8.6	8.7	2.1	1.5	2.5
Revised Forecast	$ 43.2	$ 9.7	$ 16.0	$ 8.7	$ 2.1	$ 1.5	$ 2.5

Power Supply Sewer & Domestic Water System Install and Upgrade

Description:
Upgrade or replace domestic water and waste water systems at southern plants, northern plants, converter stations, and an extension of the water distribution main from Rosser including a line that will run past the Dorsey station.

Justification:
Ensure safety and compliance with legislation. The lack of filtration systems result in organic and other matter reacting with chlorine treatment to create possible carcinogenic substances.

In-Service Date:
March 2012.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 15.1	$ 4.1	$ 1.6	$ 1.3	$ -	$ -	$ -
Increase (Decrease)	-	3.2	1.8	(0.6)	-	-	-
Revised Forecast	$ 15.1	$ 7.3	$ 3.4	$ 0.7	$ -	$ -	$ -

Power Supply Domestic

Description:
This program consists of projects whose individual costs are of a relatively small amount. These projects are required to provide safe, reliable, efficient power supply, and to replace plant facilities which are at the end of their useful life.

Justification:
Enhancements or rehabilitation to the power supply facilities will ensure a safe reliable and efficient source of energy.

In-Service Date:
Ongoing.

Revision:
Revised escalation rates.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	NA	$ 19.4	$ 19.8	$ 20.2	$ 20.6	$ 21.0	$ 135.0
Increase (Decrease)		(0.3)	(0.5)	(0.5)	(0.5)	(0.5)	(2.9)
Revised Forecast		$ 19.1	$ 19.3	$ 19.7	$ 20.1	$ 20.5	$ 132.1

TRANSMISSION:

Winnipeg - Brandon Transmission System Improvements

Description:
Perform environmental assessments and route selection, design and construct transmission and terminal facilities to provide firm supply to Portage South as follows: *Transmission:* 230 kV line 70 km Dorsey - Portage South, 230 kV double circuit line with only one side strung. *Terminations:* Extend 230 kV facilities at Dorsey and Portage South. Install three 10 MVAR, 66 kV capacitor banks at Portage South. Extend the 66 kV facilities with the addition of one breaker, one selector switch, three circuit switchers, three disconnect switches, and associated equipment. Replace one existing 66 kV breaker. Install a fourth 54 MVAR 115 kV capacitor at Brandon GS to match the existing installation of capacitors, including the associated circuit switcher and disconnects. *Communications*: Integrate with existing facilities at Dorsey and Portage South stations.

Justification:
These facilities provide improvements required to supply Western Manitoba area future load growth.

In-Service Date:
October 2014.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 40.0	$ 1.4	$ 1.6	$ 3.6	$ 3.7	$ 5.2	$ 22.0

Transcona East 230-66 kV Station

Description:
Design and build a new 230-66 kV station adjacent to the existing Transcona station. Make provision for a second bank and ring buses.

Justification:
This station is required to supply increased load to East Winnipeg.

In-Service Date:
March 2013.

Revision:
Cost flow revision, and in-service date deferred one year from March 2012.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 31.0	$ 8.6	$ 11.9	$ 9.4	$ -	$ -	$ -
Increase (Decrease)	-	(7.5)	(0.9)	3.8	5.1	-	-
Revised Forecast	$ 31.0	$ 1.1	$ 11.0	$ 13.2	$ 5.1	$ -	$ -

Neepawa 230-66 kV Station

Description:
Perform environmental assessments and route selection, design and construct terminal facilities to provide firm supply to Neepawa as follows: *Transmission:* Sectionalize 230 kV T/L D54C into Neepawa 230 kV station, creating Dorsey - Neepawa and Neepawa - Cornwallis 230 kV circuits. Build a 66 kV tie line between the new 66 kV terminal and the existing 115/66 kV station. *Terminations*: Establish Neepawa 230-66 kV station, including three 230 kV circuit breakers, a 50/66/83.3/93.3 MVA, 230-66 kV LTC transformer, six 66 kV circuit breakers and associated equipment. Adjust line protection equipment at Dorsey and Cornwallis 230 kV stations. Terminate two 230 kV transmission lines to Dorsey and Cornwallis. *Communications*: Integrate with existing facilities at Neepawa, Dorsey, and Cornwallis 230 kV stations. *System Control:* automate control, protection, equipment communications and software programming.

Justification:
These facilities provide transmission improvements required to supply Neepawa and related Western Region future load growth.

In-Service Date:
November 2012.

Revision:
Cost flow revision, and in-service date deferred 13 months from October 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 30.0	$ 5.8	$ 11.3	$ 12.8	$ -	$ -	$ -
Increase (Decrease)	-	(4.7)	2.8	(3.3)	5.1	-	-
Revised Forecast	$ 30.0	$ 1.1	$ 14.1	$ 9.5	$ 5.1	$ -	$ -

Pine Falls – Bloodvein 115 kV Transmission Line

Description:
Perform environmental assessments and route selection, design and construct transmission and terminal facilities to provide 115 kV supply to Bloodvein station as follows: *Transmission*: Construct 115 kV line 80 km Pine Falls - L48 to L5 Tap near Manigotagan. Disconnect L48 from L5 at tap location and connect L48 to new line, converting L48 from 66 kV to 115 kV operation up to Bloodvein. *Terminations*: Extend 115 kV facilities at Pine Falls. Replace 66 KV transformers at Loon Straits with two 115-7.2 kV 500 kVA transformers, and modify station for 115 kV supply. Construct 115-66 kV station at Bloodvein, including two 115-66 kV 28 MVA transformers.

Justification:
This project provides increased transmission capacity required to supply Lake Winnipeg East area load increases.

In-Service Date:
October 2014.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 34.1	$ -	$ 0.3	$ 0.9	$ 4.5	$ 21.2	$ 7.1
Increase (Decrease)	-	-	-	-	(0.1)	(0.6)	0.7
Revised Forecast	$ 34.1	$ -	$ 0.3	$ 0.9	$ 4.4	$ 20.6	$ 7.8

Transmission Line Re-Rating

Description:
Refurbish 292.6 km of double circuit and 120.7 km of single circuit 230 and 110 kV transmission lines in the Winnipeg area. Refurbish 16.9 km of double circuit and 49.2 km of single circuit 63.5 kV subtransmission lines in the Winnipeg area. Upgrade the Winnipeg River transmission line system to 100 °C. The refurbishment will correct insufficient ground clearances of line conductors. Using resagging, reconductoring, and tower extensions where required, the lines are to be upgraded to maintain safe ground clearances under thermal conductor loading. Estimate increase reflects costs for project scope increase to address all high risk, all medium risk and certain low risk spans of four 115 kV and five 230 kV transmission lines, in order to minimize public safety concerns associated with line sag violations.

Justification:
Lines in the Winnipeg area built pre-1970 cannot accommodate thermal conductor loading without violating required ground clearances. The refurbishment program will increase line to ground clearances to allow higher conductor temperatures under all potential heavy current line loads.

In-Service Date:
October 2012.

Revision:
Cost flow revision, and in-service date deferred 19 months from March 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 24.1	$ 0.4	$ 0.4	$ -	$ -	$ -	$ -
Increase (Decrease)	-	2.8	(0.4)	-	-	-	-
Revised Forecast	$ 24.1	$ 3.2	$ -	$ -	$ -	$ -	$ -

St Vital - Steinbach 230 kV Transmission

Description:
Build a new 230 kV line between St. Vital and Steinbach stations.

Justification:
Provides a 230 kV supply into the Steinbach area which will support load growth in south eastern Manitoba.

In-Service Date:
October 2020.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 32.2	$ -	$ -	$ -	$ -	$ -	$ 19.5
Increase (Decrease)	-	-	-	-	-	-	0.4
Revised Forecast	$ 32.2	$ -	$ -	$ -	$ -	$ -	$ 19.9

Rosser Station 230-115 kV Bank 3 Replacement

Description:
Replace Rosser bank 3 with a 150/200/250 MVA transformer similar to bank 1. Replace the 13.8 kV tertiary reactor supply circuit breaker and if necessary the bus. Upgrade protection as required.

Justification:
With continued load growth on the North Winnipeg and Selkirk 115 kV systems due to summer peak loads, low water conditions on the Winnipeg River and exports to Ontario; additional capacity will be required. In addition, this replacement will prevent equipment overloads in the event of a failure to bank 1 at Rosser station, and maintain export power.

In-Service Date:
March 2010.

Revision:
Cost flow revision, and in-service date deferred nine months from June 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 5.8	$ 2.4	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.2	-	-	-	-	-
Revised Forecast	$ 5.8	$ 2.6	$ -	$ -	$ -	$ -	$ -

Rosser - Inkster 115 kV Transmission

Description:
Build a second 8.2 km 115 kV line between Rosser and Inkster stations.

Justification:
A second line between Rosser and Inkster stations will alleviate contingency overloading issues on the St. James to Tylehurst 115 kV underground cable, in the event of the failure of the existing Rosser – Inkster circuit.

In-Service Date:
October 2010.

Revision:
Cost flow revision, and in-service date deferred seven months from March 2010.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 5.1	$ 2.2	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	1.1	1.4	-	-	-	-
Revised Forecast	$ 5.1	$ 3.3	$ 1.4	$ -	$ -	$ -	$ -

Transcona Station 66 kV Breaker Replacement

Description:
Replace nine 66 kV breakers and one disconnect at 115/66 kV Transcona station.

Justification:
The breakers are being replaced based on fault levels that exceed 95% of the breaker interrupting rating. These breakers are old (34-37 years), were made by a company that is no longer in business (Canadian General Electric) and cannot be certified for a higher interrupting rating. Failure of one of these lines or bank breakers will cause a transformer or line outage and lost supply power to customers between 7.3 MW and 42.8 MW, which would affect more than 10 000 customers.

In-Service Date:
February 2014.

Revision:
Cost flow revision, and in-service date deferred 15 months from November 2012.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 6.0	$ 1.0	$ 2.9	$ 1.7	$ 0.3	$ -	$ -
Increase (Decrease)	-	(1.0)	0.7	0.1	0.3	-	-
Revised Forecast	$ 6.0	$ -	$ 3.6	$ 1.8	$ 0.6	$ -	$ -

Transcona & Ridgeway Stations 66 kV Bus Upgrades

Description:
Perform the following upgrades to the 230-66 kV Ridgeway station: upgrade section of the existing 66 kV ring bus between bank 1 and liner 93 to 2500 AMPS of summer rating, replace R24 breaker and associated selector switches, upgrade section of the existing 66 kV ring bus between bank 2 and liner 95 to 2500 AMPS of summer rating, replace R28 breaker and associated selector switches, and make necessary protection and communication system changes.

Justification:
A study was undertaken to identify overloads of sections of the 66 kV ring bus at 230-66 kV Ridgeway station. Loading on the 66 kV ring bus at Ridgeway is limited by ring bus sections that are rated only 948A. In 2009, single contingencies caused unacceptable overloads on breakers R24 and R28 (107.9%), and sections of the Ridgeway ring buses (136.6%).

In-Service Date:
October 2009.

Revision:
Cost flow revision, and in-service date advanced seven months from May 2010.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 2.8	$ 1.5	$ 0.3	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.2	0.4	-	-	-	-
Revised Forecast	$ 2.8	$ 1.7	$ 0.7	$ -	$ -	$ -	$ -

Dorsey 500 kV R502 Breaker Replacement

Description:
Replace the Dorsey 500 kV R502 breaker with a new 500 kV SF6 filled breaker complete with pre-insertion resistors, remove the GE ATB-80 air blast circuit breaker, remove the 3000 PSI compressor system, and purchase one spare breaker pole.

Justification:
The R502 breaker is now operating beyond its expected useful life cycle, without an option to rebuild. Two 3000 PSI compressors work simultaneously to supply the breaker with compressed air, and are now at the end of their useful lives and need to be replaced. Without replacement, breaker failure could result in cleanup, outage and damage costs that would exceed $1.0 million. Additionally, should a second breaker fail at the same time that a breaker was being replaced; there would be a significant reduction in export power.

In-Service Date:
October 2009.

Revision:
Cost flow revision, and in-service date deferred six months from April 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 2.6	$ 0.4	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	1.9	0.2	-	-	-	-
Revised Forecast	$ 2.6	$ 2.3	$ 0.2	$ -	$ -	$ -	$ -

13.2kV Shunt Reactor Replacements

Description:
Purchase and install fifteen 13.2kV, 20MVA oil-type shunt reactors to replace all of the Ferranti Packard reactors currently in the system.

Justification:
Ferranti Packard reactors are installed at six stations throughout Manitoba (Cornwallis, Rosser, Raven Lake, Overflow River, Mystery Lake and LaVerendrye). These reactors are 45 years old and now 15 years past their estimated useful life. There are currently no replacements on hand to replace a failed reactor, which would affect system operation.

In-Service Date:
October 2018.

Revision:
New item.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ -	$ -	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	33.0	-	-	4.1	4.2	4.3	20.4

Birtle South - Rossburn 66 kV Line

Description:
Build a new 66 kV line from the 66 kV Birtle Queen station to Rossburn station. The new line will be terminated at Birtle South station with a new 66 kV breaker.

Justification:
This new transmission line will increase reliability for the Birtle South 230-66 kV station area by reducing the occurrence of line outages. In addition, voltage levels on the Birtle South 66 kV system will become adequate to maintain acceptable voltage levels at regulated distribution stations.

In-Service Date:
October 2015.

Revision:
No change.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 4.9	$ -	$ -	$ -	$ -	$ 0.1	$ 4.8
Increase (Decrease)	-	-	-	-	-	-	-
Revised Forecast	$ 4.9	$ -	$ -	$ -	$ -	$ 0.1	$ 4.8

Stanley Station 230-66 kV Transformer Addition

Description:
Purchase and install a 230-66 kV transformer and associated equipment for the Stanley Station, install transformer protection equipment, relocate 230 kV towers for line S60L outside of the station to allow for the desired 230 kV bus ring configuration, and re-terminate three lines (S60L, Line3 and Line 51).

Justification:
The absence of firm transformation capacity at Stanley station requires the station's load to be transferred to St. Leon, Portage South, and Morden Corner stations. This load transfer creates unacceptably low sub-transmission and distribution voltages, which negatively impacts customer equipment and automated processes in Morden, Winkler and the surrounding areas. This project is high risk as more than 15,000 customers could be affected.

In-Service Date:
October 2015.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 21.1	$ -	$ -	$ -	$ 1.9	$ 8.4	$ 10.8
Increase (Decrease)	-	-	-	-	(0.1)	(0.3)	0.3
Revised Forecast	$ 21.1	$ -	$ -	$ -	$ 1.8	$ 8.1	$ 11.1

Stanley Station 230-66 kV Hot Standby Installation

Description:
Install an 84/112/140 MVA, 230-66 kV transformer and associated equipment at Stanley station as a hot standby, along with transformer protection equipment.

Justification:
The low sub-transmission and distribution voltages created by transferring Stanley station load will negatively impact customer equipment and their automated processes in the towns of Morden and Winkler and the surrounding areas, potentially affecting customer service to more than 15 000 customers. Deferral will place quality of supply to local customers at risk. Customer equipment and product will be damaged, and automated (voltage sensitive) processes will be halted. In addition, one of Manitoba Hydro's major customers will be adding significant new load in 2009, also necessitating this installation.

In-Service Date:
October 2010.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 6.2	$ 3.8	$ 0.8	$ 0.1	$ -	$ -	$ -
Increase (Decrease)	-	1.1	0.4	(0.1)	-	-	-
Revised Forecast	$ 6.2	$ 4.9	$ 1.2	$ -	$ -	$ -	$ -

Ashern Station 230 kV Shunt Reactor Replacement

Description:
Purchase a 230 kV, 50MVAR shunt reactor to replace the existing Ashern station reactor.

Justification:
The Ashern reactor was installed in 1972 and has now reached the end of useful life, and is now considered a risk to the area's transmission and distribution system. When this reactor is down, one unit at Grand Rapids has to be switched from generator to synchronous condenser for the duration of the outage. Additionally, Manitoba Hydro currently does not have a system spare reactor that will support the 230 kV class.

In-Service Date:
December 2012.

Revision:
New item.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ -	$ -	$ -	$ -	$ -	$ -	$ -

Revised Forecast	$ 2.7	$ -	$ -	$ -	$ 2.7	$ -	$ -

Tadoule Lake DGS Diesel Tank Farm Upgrade

Description:
Design and install four 500 000 litre single wall above ground vertical diesel fuel tanks and associated piping, spill containment dyke modifications to accommodate the new tanks, and a fuel tank level monitoring system. Project also includes salvaging the existing 30 above ground horizontal diesel fuel tanks.

Justification:
The current permit to operate a petroleum storage facility at Tadoule Lake will expire on December 31, 2010. Of the 30 tanks, 11 are not built to Underwriters Laboratories of Canada S601 standards, and must be withdrawn from service by December 31, 2010. Additionally, the remaining 19 tanks require replacement by December 31, 2012, to be compliant with Canadian Council of Ministers of the Environment PN 1326.

In-Service Date:
December 2010.

Revision:
New item.

Interlake Digital Microwave Replacement

Description:
Build a modern communications system between the Dorsey transmission station and the Lower Nelson River. The existing Interlake Digital Microwave system is approximately 30 years old, is one of two communications systems used to operate the DC power system, and requires replacement by a modern, highly dependable communications system.

Justification:
A replacement communications system is required for dependable communications to operate the DC power system, and to provide for the continued supply of reliable power to Manitoba Hydro's domestic and export customers.

In-Service Date:
October 2010.

Revision:
Cost flow revision, and in-service date deferred ten months from December 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 19.7	$ 3.9	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(0.4)	0.4	-	-	-	-
Revised Forecast	$ 19.7	$ 3.5	$ 0.4	$ -	$ -	$ -	$ -

Communication System - Southern MB (Great Plains)

Description:
Replace part of the Great Plains microwave system with an optical fiber cable communication system. The route includes Letellier TS, Stanley TS and Crocus Plains TS; as well as the existing Great Plains microwave stations of St. Leon TS and Glenboro TS. The system will carry the Reston TS and Virden TS traffic as far as the Brandon South microwave site.

Justification:
Required to provide continuous supply of reliable power to all of Manitoba Hydro's customers.

In-Service Date:
November 2009.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 21.9	$ 1.6	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.8	-	-	-	-	-
Revised Forecast	$ 21.9	$ 2.4	$ -	$ -	$ -	$ -	$ -

Communications Upgrade Winnipeg Area

Description:
Replace part of the Winnipeg area system with optical fiber cable and electronics, in order to provide increased communication capacity to carry rural power system and administrative data traffic from the Winnipeg perimeter terminal stations to the Dovercourt system control centre and to 820 Taylor; as well as to carry increased local Winnipeg area traffic between stations.

Justification:
This communication capacity is required to carry modern high speed data traffic on Manitoba Hydro's Wide Area Network (WAN), as required by modern corporate operations. This project will provide more secure communications and replace cable that is nearing the end of useful life.

In-Service Date:
March 2010.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 7.4	$ 0.8	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(0.1)	-	-	-	-	-
Revised Forecast	$ 7.4	$ 0.7	$ -	$ -	$ -	$ -	$ -

Pilot Wire Replacement

Description:
Replace existing Pilot Wire protection schemes to provide redundancy to major industrial and residential customers that are either running without protection or must be subject to an outage because of repairs on Pilot Wire schemes that generally have no alternative routes.

Justification:
The current equipment is no longer manufactured or supported by vendors.

In-Service Date:
October 2009.

Revision:
Cost flow revision, and in-service date advanced 22 months from August 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 9.6	$ 0.4	$ 1.1	$ 0.9	$ -	$ -	$ -
Increase (Decrease)	-	0.9	0.3	(0.9)	-	-	-
Revised Forecast	$ 9.6	$ 1.3	$ 1.4	$ -	$ -	$ -	$ -

Transmission Line Protection & Teleprotection Replacement

Description:
Replace obsolete protection and associated communications equipment for 30 transmission lines with phase comparison protection schemes. The new protection will provide "A" and "B" redundant relay schemes, and all communication signals will provide "A" and "B" teleprotection units and shall have redundant channels.

Justification:
The difficulty experienced in repairing and restoring existing failed teleprotection equipment. There is concern that the remaining spare parts, which are the same vintage as the failing in-service equipment, may not be functional, and cannot be repaired. Loss of the teleprotection equipment means the loss of the high-speed primary protection for these important lines. The backup protection for these lines has been identified as too slow by system performance. The availability of these lines has a direct impact on how much power Manitoba Hydro is able to import or export.

In-Service Date:
August 2014.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 21.1	$ 2.0	$ 5.7	$ 6.4	$ 2.4	$ 1.2	$ 0.3
Increase (Decrease)	-	(0.6)	0.4	(0.3)	(0.1)	(0.1)	0.6
Revised Forecast	$ 21.1	$ 1.4	$ 6.1	$ 6.1	$ 2.3	$ 1.1	$ 0.9

Winnipeg Central Protection Wireline Replacement

Description:
Migrate the former Winnipeg Hydro area communications from metallic wireline to optical fibre cables.

Justification:
Wireline communications cables are unsuitable for most modern power system control and protection equipment applications; and therefore, retention of such cables has little future value. This project also minimizes or eliminates the need for hazardous work adjacent to high voltage cables.

In-Service Date:
September 2011.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 9.3	$ 2.4	$ 1.2	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.1	(0.6)	-	-	-	-
Revised Forecast	$ 9.3	$ 2.5	$ 0.6	$ -	$ -	$ -	$ -

Mobile Radio System Modernization

Description:
Replace the VHF mobile radio system with a modern digital system of increased capability.

Justification:
Manitoba Hydro requires a very dependable mobile radio communication system under its own control and independent of any public system, as public systems cannot guarantee service under adverse conditions and are affected by peak public traffic which can overload the system.

In-Service Date:
December 2013.

Revision:
Cost flow revision, and in-service date deferred 21 months from March 2012.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 30.7	$ 0.5	$ 13.9	$ 16.2	$ -	$ -	$ -
Increase (Decrease)	-	(0.2)	(11.4)	(7.0)	10.6	8.0	-

Cyber Security Systems

Description:
Install or upgrade security and network systems for secure remote access, industrial data network installations, and compliance to NERC standards CIP-002-1 to CIP-009-1.

Justification:
The Cyber Security Standards CIP-002-1 are part of NERC reliability standards, which Manitoba Hydro is obligated to comply with, or be subject to penalties or sanctions as per contractual arrangements with MISO.

In-Service Date:
March 2012.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 10.1	$ 2.8	$ 0.6	$ -	$ -	$ -	$ -

Revised Forecast	$ 10.1	$ 3.6	$ 0.4	$ -	$ -	$ -	$ -

Site Remediation

Description:
Conduct geotechnical investigations and remediate any hydrocarbon contaminated sites at the remaining former isolated diesel generating stations in Little Grand Rapids, Manigotogan, The Pas, Moose Lake, Norway House, Wanless, Cormorant, Cranberry Portage, Shamattawa, Berens River, and Churchill. Conduct geotechnical investigation for the various contaminated corporate facilities, prepare a report with cleanup recommendations, remediate any contaminated areas identified, and issue a final report confirming the facility and surrounding area were remediated and all areas of the work were left in accordance with applicable environmental regulations.

Justification:
Due to concerns, and in compliance with current environmental regulations and standards applicable to unrestricted use of abandoned former diesel sites, the sites must be investigated, remediated, and restored to equivalency of the surrounding area.

In-Service Date:
March 2012.

Revision:
Cost flow revision, and in-service date deferred one year from March 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 13.3	$ 3.1	$ 2.0	$ 0.3	$ -	$ -	$ -

Revised Forecast	$ 7.4	$ 0.9	$ 0.5	$ -	$ -	$ -	$ -

Station Battery Bank Capacity & System Reliability Increase

Description:
Conduct individual studies, replace and/or upgrade battery bank capacity and chargers in 156 transmission and distribution stations (over the next ten years) and seven stand-alone communications sites to meet the North American Electric Reliability Council's (NERC) battery bank sizing criteria. Includes AC service upgrades and building extension costs required to complete this project.

Justification:
Present battery banks were designed to an eight hour standard (normal DC loads), and there are concerns many may no longer meet the standard, due to additional DC loads and age related deterioration. Current corporate simulations indicate that system restoration will be inhibited if a black start situation should occur. NERC's requirements are to have a workable system restoration plan, with 12 hours capacity, dual battery systems and multiple chargers where practical, or without a restoration plan capacity for 16 hours duration. This project provides the battery bank systems for a workable system restoration plan into the future, and offers a coordinated means of changing the banks as they reach their end-of-life.

In-Service Date:
March 2015.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 46.5	$ 6.9	$ 7.0	$ 6.7	$ 6.7	$ 3.9	$ 3.6
Increase (Decrease)	-	(1.6)	(2.3)	(0.3)	(0.3)	2.7	2.7
Revised Forecast	$ 46.5	$ 5.3	$ 4.7	$ 6.4	$ 6.4	$ 6.6	$ 6.3

Red River Floodway Expansion Project

Description:
Complete communications, distribution, and transmission utility crossing work required along the Red River Floodway to accommodate the Manitoba Floodway Authority's floodway expansion. The project budget of $1.8 million represents 50% of the total estimated costs, with the other 50% to be received in contributions from the Manitoba Floodway Authority.

Justification:
Cost sharing in accordance with the agreement with the Province of Manitoba, which applies to all construction costs including: planning, design, project management, and any other associated costs required to complete the changes required to electricity and supporting communication equipment.

In-Service Date:
December 2009.

Revision:
Cost flow revision, and in-service date deferred 16 months from August 2008.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 1.8	$ -	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.3	-	-	-	-	-
Revised Forecast	$ 1.8	$ 0.3	$ -	$ -	$ -	$ -	$ -

Waverley Service Centre Oil Tank Farm Replacement

Description:
Replacement of all remaining single wall oil tanks at the Waverley Service Centre Oil Tank Farm.

Justification:
The tanks at this tank farm have reached their end of life and must be removed from service to ensure compliance with all environmental regulations. The tanks cannot be repaired due to the standard imposed by the Province of Manitoba. Failure to replace the tanks will significantly restrict the ability to provide clean processed oil for maintenance requirements.

In-Service Date:
November 2013.

Revision:
New item.

	Total	2010	2011	2012	2013	2014	2015-20

Revised Forecast	$ 3.0	$ 0.5	$ 1.0	$ 0.6	$ 0.4	$ 0.5	$ -

Transmission Domestic

Description:
This program consists of projects whose individual costs are of a relatively small amount. The majority of projects consist of additions, improvements and maintenance of transmission lines; replacement, development and upgrades to communication systems; additions and replacement of field maintenance equipment; as well as station upgrades.

Justification:
This program ensures the reliability of transmission with respect to load, outages, and import/export requirements; as well as addresses safety issues and provides the necessary support for the operation and maintenance of the transmission system.

In-Service Date:
Ongoing.

Revision:
Revised escalation rates.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	NA	$ 30.1	$ 30.7	$ 31.4	$ 32.0	$ 32.6	$ 210.0
Increase (Decrease)		(0.5)	(0.7)	(0.8)	(0.8)	(0.8)	(5.4)

CUSTOMER SERVICE & DISTRIBUTION:

Winnipeg Distribution Infrastructure Requirements

Description:
Complete assessment and emergency replacement as required of distribution underground equipment in the City of Winnipeg, including plant previously associated with Winnipeg Hydro.

Justification:
As the Underground Assessment (UGA) project progresses throughout Winnipeg, the number of failures caused by transformers has decreased. Other benefits of the UGA project include: decreased potential for employee accidents, decreased potential for public contact, extending transformer life, decreased outage duration, and increased customer satisfaction.

In-Service Date:
March 2010.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 14.9	$ 1.8	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(0.1)	-	-	-	-	-
Revised Forecast	$ 14.9	$ 1.7	$ -	$ -	$ -	$ -	$ -

Defective RINJ Cable Replacement

Description:
Replace approximately 62,500 metres of underground distribution 5kV and 15kV copper rubber insulated neoprene jacketed (RINJ) concentric neutral cable (also known as or ”Red Jacket” cable) installed in the Winnpeg area between 1955 and 1965.

Justification:
RINJ underground cable installed between 1955 and 1965 failed at a rate of 9.6 failures per 100 kilometers, which was three times higher than the failure rate at which cable replacement is recommended by the CEA. Replacement of the cable reduces the number of underground cable failures and the negative impacts on customer reliability.

In-Service Date:
March 2011.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 8.7	$ 1.1	$ 1.0	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(0.6)	1.6	-	-	-	-
Revised Forecast	$ 8.7	$ 0.5	$ 2.6	$ -	$ -	$ -	$ -

Brereton Lake Station Area

Description:
Build a new 124-12/25 kV steel station complete with two 7.5/10 MVA 124-12/25 kV LTC transformers and two 560A WVE 12 kV OCRs; 0.5 km 266.8 MCM ACSR single circuit two 124 kV line taps (consisting of steel tap-off and dead end structures) between line SK1 and the new Brereton Lake Station; and two feeder exits from the new Station to PR307. Convert 33 kV line 29 and underbuilt circuit to be operated at 12 kV. Salvage 33 kV line 29 from Rennie to Elma Tap and convert 8 km to 7.2 kV single phase.

Justification:
The existing 33 kV line from SW 293 to White Lake Station, Rennie Station and SW 1810 is at the end of its useful life. In addition, there are deficiencies associated with White Lake and Rennie stations. A new station complete with a rebuilt distribution system will provide more acceptable customer service reliability, and fewer disruptions to Ontario Hydro.

In-Service Date:
March 2010.

Revision:
Cost flow revision, and in-service date deferred 11 months from April 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 9.0	$ 0.2	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.1	-	-	-	-	-
Revised Forecast	$ 9.0	$ 0.3	$ -	$ -	$ -	$ -	$ -

Stony Mountain New 115 - 12 kV Station

Description:
Build a new Stony Mountain Station, and 1.5 miles of line to supply Bristol. Salvage existing Stony Mountain and Rockwood Stations, 33 kV lines 15 and 35, and 33 kV breakers 150 & 350 at Parkdale Station.

Justification:
The station equipment and supply lines are in a deteriorated condition and must be replaced. The 115-66-33 kV transformers that supply these stations from Parkdale are over 50 years old and reaching the end of their life expectancy. Load forecasts indicate Stony Mountain will also require a capacity increase and the only other 33 kV feed from Parkdale Station, Garson Station will require 115 kV supply by 2013. It is not economically viable to maintain a 33 kV source to only supply Stony Mountain and Rockwood Stations.

In-Service Date:
October 2009.

Revision:
Cost flow revision, and in-service date deferred seven months from March 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 5.0	$ -	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.7	-	-	-	-	-
Revised Forecast	$ 5.0	$ 0.7	$ -	$ -	$ -	$ -	$ -

Rover Substation Replace 4 kV Switchgear

Description:
Remove existing 4 kV switchgear and supervisory protection equipment and replace with new equipment capable of withstanding fault levels at this site. Install a current limiting reactor. Modify one feeder and relocate two others. Build a new substation building, replace three 66-4 kV transformer banks, extend the distribution ductline system and feeders to the new building, salvage the carpenter shop building, and the 4 kV building and its transformer banks.

Justification:
This equipment has been in-service since 1950 and its safe operation requires inefficient procedures and fault levels exceed its rating. Protective relaying, local control and metering functions are provided via electro-mechanical relays, manual switches, and analog meters located in a separate building, and provide decreasing reliability due to mechanical deterioration. During removal of the existing concrete surfacing (after removal of the first section of switchgear), it was determined that the floor could not withstand the stresses and no further floor repair can be undertaken.

In-Service Date:
November 2011.

Revision:
Cost flow revision, and in-service date deferred two months from September 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 12.7	$ 5.9	$ 1.1	$ 0.4	$ -	$ -	$ -
Increase (Decrease)	-	(5.5)	2.2	3.5	-	-	-
Revised Forecast	$ 12.7	$ 0.4	$ 3.3	$ 3.9	$ -	$ -	$ -

Martin New Outdoor Station

Description:
Install a new 3 bank outdoor station complete with 18 feeder positions and protection to replace the existing Martin station.

Justification:
Martin station is a 50 year old, two bank 12.47/4.16 kV station that has exceeded firm capacity. It is supplied from Rover station which is also being upgraded. Neither bank can be relied on as backup for the other, and there is no mobile backup available or external tie to neighbouring stations. Without improvements, 7,500 customers including residential, apartment blocks, heavy industry, and commercial businesses could be without power for an unacceptable period (48 hours minimum) in the event of an emergency, such as a transformer failure at Rover.

In-Service Date:
March 2012.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 28.2	$ 12.6	$ 9.0	$ 5.4	$ -	$ -	$ -
Increase (Decrease)	-	(11.6)	5.5	3.7	2.4	-	-
Revised Forecast	$ 28.2	$ 1.0	$ 14.5	$ 9.1	$ 2.4	$ -	$ -

Frobisher Station Upgrade

Description:
Replace both 7.5/10 MVA transformer banks with 18/24/30 MVA banks complete with 66 kV and 12.47 kV breakers, including eight new 12 kV feeder positions and two 4.5 MVAR capacitor banks. Upgrade six existing feeder automatic circuit re-closers (ACRs). Salvage banks 1 and 2 - 7.5/10 MVA transformers. Construct a new building, install a Remote Terminal Unit (RTU), communications, security system and fire protection.

Justification:
Two fully utilized 12 kV stations serving the south St Vital area were loaded to a combined 8.1 MVA over firm capacity in the summer of 2003. Load has grown an average of 2.25 MVA per year for the last ten years, and is projected to grow another 46.3 MVA over the next 16 years. Land acquisition problems prevented building a new station north of the perimeter highway.

In-Service Date:
March 2010.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 14.4	$ 2.9	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	1.5	-	-	-	-	-
Revised Forecast	$ 14.4	$ 4.4	$ -	$ -	$ -	$ -	$ -

Burrows New 66 kV-12 kV Station

Description:
Build a new two bank 66 kV-12 kV indoor station, complete with 12 feeder positions and protection to replace the Alfred and Charles stations.

Justification:
Most of the equipment in this part of Winnipeg has been in service for 75 years. Alfred Station (which supplies Charles Station) lacks access to a satisfactory alternate supply in the event of a 12 kV interruption out of Rover Station. Remedial action was recommended for both stations in the Due Diligence Report. It indicated the 4 kV switchgear lineups at Alfred and Charles Stations lack arc-resistance and at Alfred Station are sometimes underrated for the available fault current during normal operating conditions. It also had concerns that neither station has an appropriate battery room, all station transformers have patched leaks, they contain asbestos materials, and that spare parts are in short supply.

In-Service Date:
March 2012.

Revision:
Cost flow revision, and in-service date deferred three months from December 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 28.6	$ 10.7	$ 10.2	$ 2.4	$ -	$ -	$ -
Increase (Decrease)	-	(1.6)	2.0	2.6	-	-	-
Revised Forecast	$ 28.6	$ 9.1	$ 12.2	$ 5.0	$ -	$ -	$ -

Winnipeg Central District Oil Switch Project

Description:
Remove the remaining 26 oil switches located in various manhole sites throughout Winnipeg Central District. Install pad-mount switchgear and/or pad-mount transformers, and reroute existing primary feeder and customer service cables as required.

Justification:
The oil switches are corroding and are not rated for the maximum available fault current on the system. If a failure occurs or the oil must be replaced, a lengthy shutdown will be required. Replacement will alleviate the risks associated with switching primary feeders in confined spaces. Pad-mount equipment allows adequate clearances and efficiency for switching, maintaining, and upgrading for future customer load additions.

In-Service Date:
November 2009.

Revision:
Cost flow revision, and in-service date deferred five months from June 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 7.1	$ 0.5	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	1.3	-	-	-	-	-
Revised Forecast	$ 7.1	$ 1.8	$ -	$ -	$ -	$ -	$ -

William New 66 kV-12 kV Station

Description:
Build a new two bank 66-12 kV indoor station, on Manitoba Hydro owned property, with protection and communication capability to the Central District Control Centre (CDCC) and the System Control Centre (SCC) for ten feeder positions. Costs associated with the potential installation of new 12 kV feeders to the new William Station are not included.

Justification:
This project will allow for load transfers from King station, which will alleviate overloading as a result of operating limits imposed by cooling problems. Load transfers from Sherbrook station will allow for redundant feeds from different stations to supply critical services reducing the implication of a contingency equipment failure. Improvements in service reliability and accommodation for future distribution automation can be realized from new equipment. Manitoba Hydro already owns land at the south east corner of William Avenue and Tecumseh Street for a new station.

In-Service Date:
October 2012.

Revision:
Cost flow revision, and in-service date deferred ten months from December 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 10.3	$ 2.8	$ 3.9	$ 3.3	$ -	$ -	$ -
Increase (Decrease)	-	(2.3)	(0.3)	(0.2)	2.9	-	-
Revised Forecast	$ 10.3	$ 0.5	$ 3.6	$ 3.1	$ 2.9	$ -	$ -

Waverley West Sub Division Supply - Stage 1

Description:
Install 20MVA capacity complete with pad mounted voltage regulators, 24 kV-2400 kVAR capacitor banks, S&C automated switching cubicles and fibre optic communication link.

Justification:
Waverley West subdivision is a new development in an area predominantly supplied by 12 and 24 kV feeders. The 12 kV feeders cannot support more load. The nearest viable 24 kV feeder does not allow standard distribution equipment to be used due to high available fault currents. In addition, by using the 24 kV feeders, reliability to existing customers is reduced. This project is required to ensure the Waverley West subdivision customers have reliable service.

In-Service Date:
December 2009.

Revision:
Cost flow revision, and in-service date deferred two months from October 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 6.5	$ 1.4	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	3.0	-	-	-	-	-
Revised Forecast	$ 6.5	$ 4.4	$ -	$ -	$ -	$ -	$ -

St. James 24 kV System Refurbishment

Description:
Terminate a new 24 kV Feeder (J54) at the St. James station to supply the Winnipeg Airport Authority load expansion. Install a gang operated switch between feeders J25 and J54 at the Ferry Road and Ness Avenue stations, and transfer 3.7 MVA of load from J25 to J54. Convert Berry station BY612, 4 kV customers to 24 kV along Ferry Road. Build a new 115-24 kV St. James Station, new and upgraded feeders, and conversion of St. James, Ness, Berry and King Edward station feeders from 4 kV to 24 kV.

Justification:
This project is required to ensure firm supply and a reliable system in the St. James area, and to ensure the Winnipeg Airport Authority continues to experience reliable service following a planned load expansion at the facility.

In-Service Date:
March 2013.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 65.9	$ 19.1	$ 11.1	$ 22.5	$ 12.5	$ -	$ -
Increase (Decrease)	-	(17.8)	3.0	9.1	6.4	-	-
Revised Forecast	$ 65.9	$ 1.3	$ 14.1	$ 31.6	$ 18.9	$ -	$ -

Shoal Lake New 33-12.47 kV DSC

Description:
Build a two bank Distribution Supply Centre (DSC) and rebuild and convert the town distribution system.

Justification:
The existing station is 48 years old and requires re-building. The distribution system has encountered problems with voltage drops. This project represents the least cost alternative for the restoration of reliable, quality service in the foreseeable future.

In-Service Date:
September 2009.

Revision:
No change.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 3.6	$ 3.2	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	-	-	-	-	-	-
Revised Forecast	$ 3.6	$ 3.2	$ -	$ -	$ -	$ -	$ -

York Station

Description:
Add a transformer bank and switchgear for nine feeder positions.

Justification:
Increasing capacity at York station alleviates loading problems at King station and interim relief at Sherbrook, and provides for future new loads that cannot be adequately supplied by existing King, Edmonton, and York capacity.

In-Service Date:
September 2010.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 4.0	$ 1.1	$ 2.7	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.9	(0.9)	0.1	-	-	-
Revised Forecast	$ 4.0	$ 2.0	$ 1.8	$ 0.1	$ -	$ -	$ -

Cromer Station Capacity and Reston RE12-4 25 kV Conversion

Description:
Convert the westerly portion of Reston Feeder RE12-4 from 12 kV to 25 kV by November 30, 2009, and install one 66-25 kV transformer in Cromer North Station by September 2011.

Justification:
A new five mile feeder and 25 kV feeder conversion is required at Reston to address the increased demand due to oilfield exploration.

In-Service Date:
September 2011.

Revision:
New item.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ -	$ -	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	4.3	3.0	0.1	1.2	-	-	-
Revised Forecast	$ 4.3	$ 3.0	$ 0.1	$ 1.2	$ -	$ -	$ -

Brandon Crocus Plains 115-25 kV Bank Addition

Description:
Install two 15/20/25 MVA OLTC 115-25 kV transformers. Install one 115 kV breaker to connect the transformers to line BF52. Install 3x25 kV breakers, four reclosers and associated equipment to connect the transformers, and provide four additional 25 kV feeders into the industrial park.

Justification:
To supply the load growth and the industrial loads in the south Brandon area.

In-Service Date:
October 2011.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 6.3	$ 0.8	$ 3.1	$ 1.8	$ 0.4	$ -	$ -
Increase (Decrease)	-	(0.2)	-	0.1	0.2	-	-
Revised Forecast	$ 6.3	$ 0.6	$ 3.1	$ 1.9	$ 0.6	$ -	$ -

Winkler Market Feeder M25-13 Conversion

Description:
Rebuild and convert the 8 kV portion of Winkler Market Feeder WM25-13 (WM08-13) to 25 kV standards, and salvage the 3 x 500 kVA Hochfeld interchange banks.

Justification:
The load growth in the Winkler area is above Manitoba's average, and is experiencing a five year average load growth rate of 6%. This feeder is supplied by a 25 kV feeder and stepped down to 8 kV at Hochfeld. The 8 kV portion of this feeder is over 56 years old and has reached the end of its useful life. The increased load current has made it increasingly difficult to protect the 8 kV feeder ends due to lack of reach. It will soon not be possible to adequately protect the existing plant. The load has also caused feeder end voltage levels to fall below acceptable (CSA) limits.

In-Service Date:
August 2009.

Revision:
Cost flow revision, and in-service date deferred ten months from October 2008.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 2.9	$ -	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.8	-	-	-	-	-
Revised Forecast	$ 2.9	$ 0.8	$ -	$ -	$ -	$ -	$ -

Neepawa North Feeder NN12-2 & Line 57 Rebuild

Description:
Rebuild the main portion of feeder NN12-2 and a 16 km section of line 57.

Justification:
The poles have reached the end of their useful life and pole replacements must now be made or the entire line must be rebuilt. A section of line 57 that contains feeders NN12-4 and NN12-2 was built in 1953 and is over 55 years old. A field report indicates that 75% of the line is in poor condition. Larger under-build wire on feeder NN12-2 is required to improve voltage and losses, and a larger 66 kV wire is recommended to improve voltage fluctuations and losses.

In-Service Date:
February 2010.

Revision:
In-service date deferred four months from October 2009.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 1.9	$ 1.9	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	-	-	-	-	-	-
Revised Forecast	$ 1.9	$ 1.9	$ -	$ -	$ -	$ -	$ -

Perimeter South Station Distribution Supply Centre Installation

Description:
Install one 10 MVA, 66 12 kV distribution supply centre, three 7.2 kV, single-phase 585 A padmount regulators, one 15 kV three-phase padmount recloser, one 15 kV S&C automated Vistagear switching cubicle, motorized bank 12 kV switches B10 & B20, MOV lightning arresters on 66 kV and 12 kV sides of banks 1 & 2, the distribution supply centre, and all 12 kV feeders. Salvage existing manual 12 kV bank switches and gap-type lightning arresters.

Justification:
This station supplies both the south Fort Garry and La Salle communities (both fast growing) and provides a back-up supply to St. Norbert single bank station. This option addresses the non-firm capacity issues at a significantly lower cost than the initial plan, provides superior system reliability and its automatic load transfer feature offers recovery in minutes versus hours when a transformer fails.

In-Service Date:
October 2010.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 2.4	$ 0.3	$ 2.0	$ -	$ -	$ -	$ -
Increase (Decrease)	-	0.1	-	-	-	-	-
Revised Forecast	$ 2.4	$ 0.4	$ 2.0	$ -	$ -	$ -	$ -

Niverville Station 66-12 kV Bank Replacements

Description:
Replace two existing 66-12kV, 3.75/5.0 MVA transformers at Niverville station with two new 66-12kV, 7.5/10/12.5 MVA transformers.

Justification:
This project was initiated as last year's peak load readings indicated that the capacity of this station has been exceeded. In addition, the Town of Niverville is planning to develop a total of 600 residential subdivision lots over the next three years. To date, approximately 200 lots have been serviced and a request to service 160 more lots has been received.

In-Service Date:
October 2009.

Revision:
New item.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ -	$ -	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	2.6	2.6	-	-	-	-	-
Revised Forecast	$ 2.6	$ 2.6	$ -	$ -	$ -	$ -	$ -

Winnipeg Central District Underground Network Asbestos Removal

Description:
Remove or encapsulate asbestos wrap from high voltage cables currently present in approximately 1,800 manholes within the central Winnipeg area.

Justification:
Asbestos must be in a condition that does not pose a health risk to anyone in the workplace. As a result, the current exposure control plan requires the asbestos be properly sealed with a sealant, encapsulated or removed to eliminate the risk of exposure.

In-Service Date:
March 2010.

Revision:
Cost flow revision only.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 3.0	$ 0.8	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(0.1)	-	-	-	-	-
Revised Forecast	$ 3.0	$ 0.7	$ -	$ -	$ -	$ -	$ -

Gas SCADA Replacement

Description:
Replace the current Gas Supervisory Control and Data Acquisition (SCADA) system with a vendor-supported SCADA system.

Justification:
Replacement of the current gas SCADA system is required as product support is being discontinued by the vendor, and vendor alternative product does not meet the complete system requirements for Manitoba Hydro.

In-Service Date:
June 2011.

Revision:
Cost flow revision, and in-service date deferred three months from March 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 4.6	$ 1.1	$ 3.1	$ -	$ -	$ -	$ -
Increase (Decrease)	-	(0.1)	(0.1)	0.6	-	-	-
Revised Forecast	$ 4.6	$ 1.0	$ 3.0	$ 0.6	$ -	$ -	$ -

Customer Service & Distribution Domestic

Description:
This program consists of projects whose individual costs are of a relatively small amount. These projects are required to extend sub-transmission, distribution, and transformation facilities to supply service to residential, farm, commercial and industrial customers, and to replace plant facilities whose useful life has been exceeded. Specific types of expenditures that make up electric domestic items include station and line additions, modifications and rebuilds, bank additions, breaker replacements, defective cable replacement, highway changes, field maintenance equipment, and ice melting requirements. These costs are spread over many facility locations throughout the Province.

Justification:
The residential, farm, commercial and industrial loads are expected to grow at an average rate in excess of 1.5% per annum and will require a program of additions to the system to accommodate these anticipated loads.

In-Service Date:
Ongoing.

Revision:
Revised escalation rates.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	NA	$ 118.2	$ 120.6	$ 123.0	$ 125.5	$ 128.0	$ 823.4
Increase (Decrease)		(2.3)	(3.1)	(3.1)	(3.2)	(3.3)	(20.8)
Revised Forecast		$ 115.9	$ 117.5	$ 119.9	$ 122.3	$ 124.7	$ 802.6

CUSTOMER CARE & MARKETING:

Advanced Metering Infrastructure

Description:
Purchase and install an automated metering infrastructure (AMI) communication network to remotely read and electronically disseminate electric meter readings and other relevant customer information to appropriate departments and divisions.

Justification:
Satisfies the ongoing need for routine, periodic meter readings in customer billing as well as provides 'on demand' readings to respond to customer inquiries. Other benefits include: increased customer satisfaction due to greater billing accuracy; better detection of theft of service, meter tampering and defective meters; greater flexibility in the timing and consolidation of billings; and improved detection of customer and system power outages with shortened restoration times.

In-Service Date:
March 2015.

Revision:
Cost flow revision, and in-service date advanced one year from March 2016.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 30.9	$ 3.9	$ 4.0	$ 4.0	$ 4.1	$ 4.3	$ 8.8
Increase (Decrease)	-	(3.9)	-	1.3	1.3	1.3	(0.3)
Revised Forecast	$ 30.9	$ -	$ 4.0	$ 5.3	$ 5.4	$ 5.6	$ 8.5

Customer Care & Marketing Domestic

Description:
This program covers the additions and replacements of electric meters.

Justification:
As required for the connection of new customers to the system, as well as replacement of existing time expired or faulty meters.

In-Service Date:
Ongoing.

Revision:
Revised escalation rates.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	NA	$ 2.6	$ 2.6	$ 2.7	$ 2.7	$ 2.8	$ 18.0

FINANCE & ADMINISTRATION:

Corporate Buildings

Description:
Cyclical acquisitions, refurbishments, and/or replacement of corporate facilities throughout the Province.

Justification:
Enables a safe, efficient, and productive environment for staff and customers.

In-Service Date:
Ongoing.

Revision:
No change.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	NA	$ 8.0	$ 8.0	$ 8.0	$ 8.0	$ 8.0	$ 40.0
Increase (Decrease)		-	-	-	-	-	-
Revised Forecast		$ 8.0	$ 8.0	$ 8.0	$ 8.0	$ 8.0	$ 40.0

Workforce Management (Phase 1 to 4)

Description:
Implement a Workforce Management solution to integrate and automate the Customer Care & Marketing planning and dispatch functions, as well as provide for in-truck computing.

Justification:
Facilitates the integration of field processes to improve customer service and field productivity; as well as, reducing clerical functions and employee travel time.

In-Service Date:
June 2011.

Revision:
Cost flow revision, and in-service date deferred 27 months to June 2011.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	$ 11.3	$ -	$ -	$ -	$ -	$ -	$ -
Increase (Decrease)	-	3.9	1.0	-	-	-	-
Revised Forecast	$ 11.3	$ 3.9	$ 1.0	$ -	$ -	$ -	$ -

Fleet

Description:
Cyclical procurement, refurbishment and/or replacement of corporate fleet vehicles and equipment.

Justification:
To provide a fleet of safe, reliable and efficient corporate vehicles and equipment.

In-Service Date:
Ongoing.

Revision:
No change.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	NA	$ 13.3	$ 13.5	$ 13.8	$ 14.1	$ 14.3	$ 92.2

Revised Forecast		$ 13.3	$ 13.5	$ 13.8	$ 14.1	$ 14.3	$ 92.2

Finance & Administration Domestic

Description:
The programs consist primarily of information technology hardware, software, application development, and associated services to the corporation. In addition, there are programs to provide for property easements and to a lesser degree equipment for fleet, property and materials management.

Justification:
Computer system enhancements are required throughout the corporation to achieve ongoing improvements in resource productivity and reliability. Property easements and equipment purchases are required for supporting the appropriate areas of the corporation.

In-Service Date:
Ongoing.

Revision:
Revised escalation rates.

	Total	2010	2011	2012	2013	2014	2015-20
Previously Approved	NA	$ 24.6	$ 25.1	$ 25.6	$ 26.1	$ 26.6	$ 171.1
Increase (Decrease)		(0.5)	(0.7)	(0.7)	(0.7)	(0.7)	(4.3)

Demand Side Management

Description:
Design, implement and deliver incentive based PowerSmart conservation programs to reduce gas consumption and greenhouse gas emissions in Manitoba. When combined with savings realized to-date, total natural gas savings of 172 million cubic meters are expected to be achieved by 2025.

Justification:
Provides customers with exceptional value through the implementation of cost-effective energy conservation programs that are designed to minimize the total cost of energy services to customers, position the Corporation as a national leader implementing cost-effective energy conservation and alternative energy programs, protects the environment, and promotes sustainable energy supply and service.

In-Service Date:
Ongoing.

Revision:
Refinements to existing programs to reflect current information.

	Total	2010	2011	2012	2013	2014	2015-20

THE MANITOBA CLEAN ENVIRONMENT COMMISSION

IN THE MATTER OF: Bipole III Transmission Line Project
Environmental Impact Statement

INDEX OF ARGUMENT

THE TASK BEFORE THE CEC

Terms of Reference were issued by the Minister of Conservation and Water Stewardship on December 5, 2011 requesting the Clean Environment Commission (the "CEC") to review and evaluate Manitoba Hydro's Environmental Impact Statement on its Bipole III Transmission Line Project ("the Project") and its public consultation summary. As part of its assessment of the Project, the CEC was also asked to hold public hearings to obtain input from stakeholders and the public.

On August 23, 2011, the Terms of Reference were clarified by the Minister of Conservation and Water Stewardship in a letter to the CEC wherein he stated: "In response to your specific question about a Needs For and Alternatives To (NFAAT) review, the Terms of Reference, which were issued in December 2011, do not include instruction for the CEC to conduct an NFAAT."

Numerous Information Requests, from stakeholders, Participants, and the Technical Advisory Committee, were answered over the course of the spring and summer of 2012. In addition, supplemental information was filed in both 2012 and in 2013 to further add to the materials filed in the EIS.

The CEC is now to provide a report outlining the Commission's review and recommendations on whether a licence should be issued to Manitoba Hydro for the Bipole III Project, taking into account the entirety of the evidence which is now before it.

If the Project is recommended, the CEC is also to propose the measures it suggests to mitigate and manage any residual effects and to outline what future monitoring is recommended.

This task is one of great importance to all Manitobans and has not been taken lightly by any of the parties.

NEED AND RELIABILITY

Reliability is Manitoba Hydro's primary concern and that concern underlies the whole proceeding. It is the reason this Project has been advanced. Manitoba Hydro is the only utility in the world that is dependent upon one corridor and one station for 70% of its northern hydro generation. The loss of this supply would necessitate rotating blackouts for extended periods. Our customers and regulator would consider Manitoba Hydro negligent if steps are not taken to address this significant supply risk should a catastrophic event occur. The North American Electric Reliability Corporation (NERC) is encouraging industry to design more robust systems to minimize impact of catastrophic events.

It is not possible to guarantee to Manitobans that any transmission system built can withstand every force of nature and that all outages of various causes can be avoided. However, with the construction and operation of this Project as proposed for 2017, reliability will be significantly enhanced through redundancy and increased physical separation of its facilities. The risk of serious outages in the future will be significantly reduced and the anticipated increased needs of Manitoba for domestic load will be better met.

None of the Participants or public presenters has argued that the need for reliability is not a grave concern. No party seriously challenged the assertion that there would be a catastrophic impact to both Manitobans and their economy should the Dorsey Converter Station ("Dorsey") fail – limiting the supply of energy up to three years, or should the two existing Bipole lines simultaneously go down – limiting the supply of energy for six to eight weeks. The 6 to 8 week estimate is based upon Manitoba Hydro's experience in line restoration over many decades.

The Bipole III Transmission Line Project is the best solution to improve reliability of the Manitoba Hydro system and the security of electricity supply. It is the culmination of work done over many years, using its expertise and experience in constructing, operating and maintaining over 18,000 kilometres of Alternating Current (AC) transmission lines and over 1,800 kilometres of Direct Current (DC) transmission lines over the past 60 years, as well as the construction and operation of three converter stations. Manitoba Hydro had an obligation to be prudent and rigorous in the planning and advancement of this Project, and it did so.

It is an important Project that needs to go forward at this time to ensure a safe and reliable source of electricity for years to come. The clear evidence before the Commission is that there will be a deficiency of 1,500 megawatts for domestic load by 2017, should Dorsey or the two existing Bipole lines be severely affected by an event.

Despite all of the evidence and the documentation that has been filed, the urgency for the Project may still not be well understood. It likely won't be truly understood until there is a significant outage at Dorsey, or until the two existing Bipole lines are damaged in the same event. This is not dissimilar to the Floodway, which was not well understood by some, nor appreciated, until the flood of 1997.

By direction of the Minister, alternatives to the Project were outside the scope of this hearing. However, the Bipole III Coalition ("the Coalition") provided a two-pronged proposal for consideration which suggests new technology be used (underground cables), new routes be selected through lands not yet assessed environmentally nor discussed with the public through consultation, and significant changes be made to the configuration of the backbone of Manitoba Hydro's electrical system.

The Coalition proposal recommended that Manitoba Hydro initially relocate the converter station for a new Bipole II from Dorsey to the Riel site by:

- installing new converters;
- constructing a new direct current (dc) line tapped off the Bipole II line north of Dorsey or by constructing underground cables from Dorsey to Riel; and
- deferring the Bipole III Project until 2025, with the southern converter station in the vicinity of LaVerendrye station.

This relocation proposal had previously been assessed by Manitoba Hydro, but was deemed unacceptable. As set out in the rebuttal evidence filed by Manitoba Hydro on March 5, 2013, Manitoba Hydro determined that the Coalition proposal does not address the critical need for improved reliability in the event of a corridor loss.

In particular, the Coalition proposal itself:

- fails to address the risk of a weather, or other, event causing the simultaneous loss, at any time of the year, of both Bipole I and II lines located in the Interlake corridor;
- only deems it appropriate to consider the shoulder and off-peak months for corridor outage, ignoring studies that indicate wide front winds and wind and ice storms can occur at any time of the year;
- fails to understand that load shedding of hundreds of megawatts, for weeks on end, is not acceptable to the customers of Manitoba Hydro and, instead, recommends that Manitoba Hydro shed load of 800 megawatts should an outage occur;
- fails to take into account that Manitoba Hydro's DC system is already fully loaded when it suggests that it could manage ice accretion by increasing the loading;
- does not address concerns with ice build up on sky wires and insulators which could also cause outages, though this risk was acknowledged;
- ignores the risk studies that Manitoba Hydro has done that demonstrate the high risk of a corridor outage at any time of the year;
- does not ever address the supply deficit for the corridor outage and requires further investment after 2025 that costs at least $1.2 billion more than the Manitoba Hydro Bipole III plan;
- relies on unachievable levels of imports in the event of a severe outage and underestimates the risks in relying upon such imports when the Corporation only has 700 megawatts of firm import capability;
- underestimates the time and effort required for Bipole I and II line restoration in the event of a severe outage;
- fails to provide for adequate spare capacity to avoid extended outages (both anticipated and unforeseen) during the relocation of the new Bipole II from Dorsey to Riel without Bipole III being in service to provide that extra capacity;
- minimizes the risk and complexity of separating the controls and other technical concerns while separating a heavily utilized Bipole I and II;
- proposes an incomplete Bipole I and II paralleling scheme;

- does not properly address the reliability and technical issues that would have to be resolved in the AC and DC systems if LaVerendrye were to be used as the Bipole III southern converter station instead of Riel;
- ignores the increased risk of failure caused by the necessity of leaving underground cables in the ground for two to three years prior to being energized; and
- overlooks the fact that the existing converter equipment at Dorsey cannot be maintained as a backup as it will no longer be technically compatible with the updated converter equipment at the Henday Converter Station designed to work with the new Riel converter.

It was also determined that the LaVerendrye proposal, in the long run, is more costly and would result in considerable delays in the delivery of enhanced reliability. For example:

- a new 500kV AC line must be built from LaVerendrye to Riel and several 230 kV lines must also be constructed to protect against the increased risks of the loss of that line; remedies would have to be studied and developed for a multitude of technical issues, as acknowledged by Messrs. Derry, Woodford and Lawson, such as:
  - the multi-infeed effects and dc performance of the proposed three bipole system;
  - short circuit levels at Dorsey;
  - resonance on the dc side of the system;
  - design of a complete 500 kV ring around Winnipeg; and
  - heavy transmission loading across Winnipeg from west to east and the impact of further power injections at LaVerendrye;
- a minimum of 65 kilometres of underground cables must be purchased and transported from abroad at a cost of at least $400 million (in 2012 dollars) more than for overhead lines, and significant investigations into licensing, transportation, storage, handling and installation would be required; [1]
- the useful life of an underground cable (approximately 40 years) is less than half the useful life of an overhead line (approximately 100 years), resulting in additional costs in the order of $422 million in 2012 dollars for underground cable replacement.

[1] If the shortest route is not selected due to its inappropriateness, or if Mr. Woodford's proposal for further underground cable is accepted, significantly more cable must be purchased, transported and installed;

Not even discussed in the Coalition proposal are the needs for further public engagement, extensive environmental assessment and additional licensing processes due to the new routes proposed outside of the study area. In addition, the new underground technology being introduced would have a significantly different potential impact on the environment than overhead lines. These would be both costly and time-consuming, and would certainly delay implementation of the reliability solutions sought by several years.

Exhibits MH 115 and MH 116 – Manitoba Hydro Rebuttal

Evidence of Ed Tymofichuk, October 1, Page 92, Pages 101 – 104, and Page 142, and October 29, Page 2029

Evidence of Gerald Neufeld, October 1, Page 103

Evidence of the Coalition, March 5, Page 6268, Pages 6273 – 6275, Page 6282, Page 6310, Page 6314

For the above reasons, Manitoba Hydro is of the strongest view that the CEC should not pursue the proposal of the Bipole III Coalition any further.

THE ENVIRONMENTAL ASSESSMENT CARRIED OUT BY MANITOBA HYDRO

The Chairman, in his opening remarks, stated that "the challenge for the proponent … is to assure that the record is complete, and that the panel, as well as the public, understand the conclusions set out in the Environmental Impact Statement."

Transcript, October 1, Page 10

In Manitoba Hydro's Opening Statement, it acknowledged that responsibility and stated:

> "Our purpose as a proponent … will be to demonstrate that, in fact, we have done our work in planning and assessing this project, that we have done our work responsibly and professionally…."

Transcript, October 1, Page 18

Because the Project crossed five eco-zones and seven eco-regions, and as the depth and diversity socially and biophysically from north to south was tremendous – from terrain to wildlife to people, Manitoba Hydro felt a generalized route selection process was not sufficient.

Evidence of Pat McGarry, October 5, Page 996

There are a myriad of issues to account for in routing a transmission system of this magnitude and with such distinctly different components. Manitoba Hydro embarked upon a comprehensive, multi-stage environmental assessment process starting in the fall of 2008 and engaged the services of numerous 20 biophysical and socioeconomic experts to assist it in evaluating the Project and balancing the multitude of interests (often competing), while still meeting the need for reliability and technical feasibility. The work was done thoroughly, responsibly and professionally, and the route chosen has the least impact on the west side of the Province.

Evidence of Ed Tymofichuk, October 1, Pages 142 – 143

Evidence of Gerald Neufeld, October 1, Page 153

Manitoba Hydro then brought together the people who were involved in the planning, assessment, and analysis, and those involved in making the predictions as to impact, to testify before this Commission and to answer any and all questions relating to their areas of expertise, to ensure there was a good understanding of the conclusions set out in the Environmental Impact Statement ("EIS") and the supplemental Environmental Assessment filed January 28, 2013 ("EA").

The CEC was then asked by Manitoba Hydro, in its Opening Statement, to keep five questions in mind as it listened to the testimony provided by the proponents and the participants. If the answer to each question was "yes", the CEC could then recommend to the Minister that the Project be licensed.

Transcript, October 1, Pages 20 - 21

Have those questions been answered to the satisfaction of the CEC, such that a licence can now be recommended? Manitoba Hydro believes that they have. It believes that the record is complete, and that its conclusions are understood, appropriate and supportable.

1. DID MANITOBA HYDRO ENGAGE THE PUBLIC AND DID WE RESPOND IN A CONSTRUCTIVE AND PRACTICAL WAY TO WHAT WE HEARD?

Manitoba Hydro engaged in an extensive environmental assessment consultation process ("EACP") which had three main goals:

i) Providing timely and relevant information on the Project to the public and stakeholders;

ii) Providing an opportunity for receiving feedback from the public and stakeholders; and

iii) Incorporating that feedback into Project decision-making.

Evidence of Trevor Joyal, October 2, Page 309

At its simplest, it was Manitoba Hydro's intention to make a better project.

Evidence of Pat McGarry, October 3, Pages 651 - 652

Due to the scope and breadth of the Project, and recognizing both the unique rights and interests of Aboriginal peoples and the challenges associated with engaging with many northern and Aboriginal communities, such as travel constraints, the EACP was divided into a public consultation process and northern and Aboriginal engagement process. The Aboriginal engagement process was not intended to deal with rights-based issues, as that is the responsibility of the Province. Rather, it was intended to deal with the concerns and potential impacts of the Project.

Evidence of Deirdre Zebrowski, October 3, Page 453

Evidence of Deirdre Zebrowski, October 29, Pages 2042 - 2043

Having received the direction from the Government of Manitoba to build the Project on the west side of Province in September of 2007, both engagement processes then commenced in 2008. They utilized a four round approach which occurred simultaneously. Briefly, those four rounds could be described as follows:

i) **Round 1** (fall of 2008):

- Providing broad Project information and identifying preliminary issues;

ii) **Round 2** (spring of 2009):

- Describing the site selection and environmental assessment process and determining constraints and opportunities for routing in the larger study area;

iii) **Round 3** (fall of 2009):

- Examining alternate routing options within 4.8 kilometre (or three mile) wide corridors;

iv) **Round 4** (summer of 2010):

- Presenting the preliminary preferred route within a 66 metre wide corridor.

Evidence of Trevor Joyal, October 2, Pages 310 - 311

Evidence of Deirdre Zebrowski, October 3, Page 453

A variety of notification and engagement mechanisms were utilized throughout the EACP. Advertisements were placed on television, on the radio, in local and provincial newspapers, and on posters placed in strategic community locations. 19,000 postcards were sent out at the start of Round 4, and property owners within a half mile of the Preliminary Preferred Route were invited to any of the 42 Landowner Information Centers which had been established. 244 meetings were held in total during those four rounds with communities, municipalities, First Nations, Northern Affairs Community Councils ("NACCs") and Aboriginal organizations. 137 community and regional Open Houses were held, some of which were added due to requests from the public. Manitoba Hydro also created a Project-specific website, a toll-free Project information line, and email address, all of which were kept open and up to date to ensure the public had continual access to Project information. They continue to be available to any interested party.

Evidence of Trevor Joyal, October 2, Pages 310 – 319; Pages 632 – 633; Pages 658 - 660

Direct mail outs were not provided to landowners in Rounds 1 through 3 as the Project study area at that stage was extremely large and would have required contacting thousands of individuals, most of whom are not now affected by the Final Preferred Route ("FPR"). Even in

Round 3, there were still three routes, over 1,300 kilometres long and 4.8 kilometres wide. Broad notification methods were deemed more appropriate.

Evidence of Trevor Joyal, October 3, Page 629

Evidence of Pat McGarry, October 3, Page 629

In addition to the engagement described above, the Aboriginal engagement process included a sharing of Aboriginal Traditional Knowledge ("ATK"). This was accomplished through workshops, through meetings arranged as part of existing processes and contractual obligations, and through self-directed studies. 49 invitations were sent out to First Nations, NACCs and the Manitoba Métis Federation ("MMF"). 19 chose to participate in workshops, while eight, including the MMF, chose to do self-directed studies.

Exhibit MH – 52

Evidence of Virginia Petch, October 30, Page 2410

Over the course of the four rounds, there was participation from 26 First Nations, the Manitoba Métis Foundation, 23 Northern Affairs Communities, and five Aboriginal or regional organizations.

Evidence of Deirdre Zebrowski, October 3, Pages 453 - 461

Manitoba Hydro funded eight self-directed ATK studies carried out by Fox Lake Cree Nation ("FLCN"), Tataskweyak Cree Nation ("TCN"), Opaskwayak Cree Nation ("OCN"), Sapotaweyak Cree Nation, Wuskwi Sipihk First Nation, Swan Lake First Nation ("SLFN"), Long Plain First Nation and the MMF.

Evidence of Deirdre Zebrowski, October 3, Pages 462 - 472

Funding was granted to the Southern Chiefs Organization in Round 3 for a two day gathering to share information on the Project with both Treaty 2 and Treaty 4 First Nations, which would have included Pine Creek First Nation and Wuskwi Sipihk First Nation.

Evidence of Deirdre Zebrowski, October 3, Page 624

Engagement with Pine Creek First Nation on matters of particular interest to it was ongoing and continued up to and including resumption of the hearing in March of 2013. Meetings and open houses were held with PCFN as early as Round 1, an ATK workshop was arranged and held in the community, and 17 key person interviews took place with individuals identified by the community itself.

Evidence of Deirdre Zebrowski, October 3, Pages 895 – 896; Page 898; Page 902

Answer to Undertaking, October 29, Page 2023

Although PCFN did express concerns about the ATK workshop, it acknowledged that the community was in a state of flux at the time and was not in a position to adequately respond to requests from Manitoba Hydro for more information.

Evidence of Warren Mills, March 6, Page 6486

Manitoba Hydro worked closely with FLCN further on the impacts of the Project pursuant to the Impact Settlement Agreement signed by the parties and, as a result, two background papers with the parties' perspectives were filed.

Evidence of Deirdre Zebrowski, October 3, Pages 473 - 474

Manitoba Hydro also demonstrated its willingness to continue discussions on Project impacts throughout the process and provided numerous examples including its work with TCN.

Evidence of Deirdre Zebrowski, October 3, Pages 463 - 477

Communications were exchanged with Peguis First Nation ("PFN") about funding for a self-directed ATK study. Manitoba Hydro was of the view that PFN was not within the Project Study Area and, as such, funding was not provided. Further, land required for the Riel Station had already been purchased and is not on Crown leased land. Thus, it does not affect PFN's future selection of Treaty Land Entitlement. Manitoba Hydro did, though, indicate that it was more than willing to meet to discuss any routing concerns it may have. No response to that invitation was ever received. Six months to one year later, PFN requested financial support for a land use and occupancy study, the results of which could possibly be applicable to the Project. Manitoba Hydro did provide some modest financial support for this undertaking and asked that the results be shared with it if it was shown that the results were indeed applicable to the Project or any other Manitoba Hydro initiative. No response was received.

Evidence of Deirdre Zebrowski, October 4, Pages 874 - 876

Manitoba Hydro also provided funding to WSFN to complete a self-directed ATK Study. At the time of filing the EIS, WSFN had provided Manitoba Hydro with some maps but not it's final ATK Study Report. Manitoba Hydro remains committed to working with communities, including WSFN, to discuss issues of concern and how they might be addressed through the Environmental Protection Plan.

Evidence of Deirdre Zebrowski, October 3, Pages 470 - 471, 479 - 482

ATK Technical Report # 2, Page 19

With respect to the engagement of MMF, MMF chose to do a traditional land use and knowledge study to identify any Métis rights and interests that had a potential to be affected by the Project. It was provided with $500,000 to do that study. The MMF developed a community engagement process through this work and used three different methodologies/mechanisms to gather information. That report was received by Manitoba Hydro on September 1, 2011.

Evidence of Deirdre Zebrowski, October 3, Pages 465 - 466

Evidence of David Chartrand, Nov. 14, Pages 4756 - 4759

Two specific meetings were held with the Winnipeg office of the MMF as part of the EACP process. Regional and Community Open Houses were held across the study area where representatives from MMF Locals could attend if desired. However, Manitoba Hydro was specifically directed by the Winnipeg home office of the MMF to deal with them and not with the locals, so meetings with the MMF Locals were not arranged.

Evidence of Deirdre Zebrowski, October 4, Pages 672 - 676

There has also been a Manitoba Hydro/Manitoba Métis Federation relationship task force in existence since 2004, negotiated by the President of the MMF, David Chartrand, whose purpose was to be a forum by which the two organizations could communicate with each other on a variety of topics including Manitoba Hydro projects such as this one.

Evidence of David Chartrand, Nov. 14, Pages 4756 - 4759

Manitoba Hydro also engaged with resource users in the vicinity of the Final Preferred Route. It did so through the application of its Trappers Notification/Compensation Policy to affected commercial trappers, and through communication with those trappers, trapping associations and other stakeholders whose commercial trapping activities may be affected by the Project. Manitoba Hydro notified lodge and outfitting operators at the onset of Round 4 to ensure these operators were aware of and had opportunity for input to the assessment of the Project. During the recent route adjustment EACP in December 2012 outfitters were asked again for their input, and were also encouraged to participate in the CEC process itself.

Evidence of Vince Kuzdak, October 30, Page 2343

Evidence of Paul Turenne, March 11, Page 6485

After the filing of the EIS, Manitoba Hydro continued to have ongoing engagement with Aboriginal communities, organizations and NACCs. Some of the items that have been discussed include the Access Management Plan, Environmental Protection Plan, employment and business opportunities, and so on.

Evidence of Deirdre Zebrowski, October 30, Page

Evidence of James Matthewson, November 8, Page 4049, Pages 4069 – 4071, Pages 4077 – 4080, Pages 4091 – 4094, Pages 4116 – 4117, Pages 4130 – 4131, Pages 4143 – 4145, Pages 4157 – 4164, Pages 4170 – 4172, and Page 4174

During the preparation of the Supplemental EA relating to the routing concerns expressed by Manitoba Conservation and Water Stewardship's Environmental Assessment Branch, Manitoba Hydro undertook a second engagement process with the public in general and with stakeholders, First Nations, NACCs, landowners and the MMF. Once again, a variety of notification methods and consultation activities were used to ensure local communities, interest groups, stakeholders, First Nations, NACCs, landowners and the MMF were informed of, and could participate in, these EACP activities. In total, 216 direct letters were mailed, 197 individuals signed into 12 venues where 27 comment sheets and eight Landowner Information Centre forms were submitted. Within a few days of letters being sent out to those First Nations communities directly affected by the routing revisions, telephone follow-up was also carried out. Manitoba Hydro held community engagement activities with 16 First Nation and NACC communities. Manitoba Hydro attempted to engage with the MMF but was unable to come to a mutually acceptable format of engagement.

Evidence of Trevor Joyal, March 4, Pages 5946 - 5961

Evidence of Trevor Joyal, March 6, Page 6382

Manitoba Hydro also continued in its efforts to engage with the MMF with respect to the most recent route alternatives being investigated. The unfortunate results of those efforts are contained in the two proposals and letters between legal counsel attached to the Supplemental EA filed on January 28, 2013.

Exhibit MH 109

Manitoba Hydro has demonstrated that its public and Aboriginal engagement process was thorough, thoughtful, effective, and professional. The adaptive process and inclusive nature of the engagement program allowed all stakeholders the opportunity to participate at various stages throughout the route selection process.

DID IT THEN RESPOND TO WHAT WAS HEARD IN A CONSTRUCTIVE AND PRACTICAL WAY?

There are numerous examples demonstrating that it did, proving the value of its public consultation process.

57 individual requests for route changes came out of the Round 4 consultations. Of the 57 requests, 23 adjustments were made to the preliminary preferred route. In addition, a route change in the Tourond area was undertaken to address concerns expressed in that area post-EIS submission. This involved an alternative route review and an additional engagement process with landowners and the general public.

Evidence of Trevor Joyal, October 2, Pages 329 - 331

Evidence of Pat McGarry, October 2, Pages 383 – 384

During the engagement process, Manitoba Hydro was requested by SLFN to provide further support for them to complete work in the areas of botanical surveys and archaeology. This support was in addition to the financial support provided to complete a traditional knowledge study. The work completed has identified the location of rare botanical species that are of importance to that First Nation and a number of previously unknown archaeological sites. Efforts will now be made through the Environmental Protection Plan to protect them and a commitment has been made to ensure community members are present when precise tower location is being determined to avoid particular areas of concern.

Evidence of Deirdre Zebrowski, October 3, Pages 467 – 469

Evidence of Pat McGarry, March 6, Pages 6416 - 6419

Manitoba Hydro is also continuing discussions with SLFN regarding routing through an area of cultural and heritage interest to SLFN.

Evidence of Pat McGarry, March 6, Pages 6419-6420

As a result of discussions with TCN, and the funding by Manitoba Hydro for two reports, two of three route changes proposed by TCN were incorporated into Final Preferred Route.

Evidence of Deirdre Zebrowski, October 3, Pages 469 – 470

Information about the use of traditional berry picking areas and medicinal plant gathering was obtained during the EACP process from First Nations such as Pine Creek First Nation ("PCFN"). This information led directly to the identification of an additional Valued Environmental Component ("VEC") by the expert on terrestrial ecosystems and vegetation, which was then incorporated into the review of domestic resource use. That input further led Manitoba Hydro to carry out additional review of certain segments such as B3 in Section 8, to give the vegetation VEC a higher rating, and to choose an alternative route. Further, Manitoba Hydro heard concerns about the spraying of blueberries with herbicides and has committed not to do so.

Evidence of Trevor Joyal, October 3, Page 616

Evidence of Pat McGarry, October 4, Pages 687 – 690

Evidence of Kevin Szwaluk, October 29, Page 2264

Evidence of Glenn Penner, March 12, Pages 6784 - 6786

More recently, during the course of this hearing, concerns were heard from Pine Creek First Nation ("PCFN") about flooding and other water issues. Such concerns had not been identified previously by Manitoba Hydro's expert, but Manitoba Hydro reacted by having its engineers conduct studies on the flooding problem and what, if any, the Project would have on it. Further, they provided presentations to both the community and the CEC. It was ultimately determined that the change in runoff from the Project would be undetectable.

Evidence of Kristina Koenig, Nov. 7, Pages 3752 - 3770

PCFN's concerns with respect to other cultural and heritage resources will not be ignored and will be taken into account, and addressed, through the construction process and environmental monitoring.

Evidence of James Matthewson, November 8, Page 4154

Moose, in the EIS, was not identified as a VEC of concern. Moose concerns were not cited by the MMF in its report dated August of 2011. Further Game Hunting Areas closures did not occur until July of 2011. At the time it first came to the attention of Manitoba Hydro, it had already completed Round 4 of the EACP process and was already finalizing the EIS for filing in the fall of 2011.

Evidence of Deirdre Zebrowski, October 3, Page 479

Evidence of Pat McGarry, October 4, Pages 668 – 669

Manitoba Hydro has demonstrated its responsiveness to those more recent concerns. Manitoba Hydro asked its experts to carry out further study and field work on moose in Game Hunting Area ("GHA") 14 and GHAs 19A/14A and filed two reports prior to resumption of the hearing in March. At the direction of MCWS, alternate routes have been examined in those areas arising out of concerns for moose and analysis done to determine if changes would benefit moose populations in the future.

Exhibit MH 107 and 109

Numerous concerns expressed about diagonal lines on agricultural land were also taken into account and altered the Final Preferred Route.

Evidence of Trevor Joyal, October 3, Page 616

Additional concerns were brought forward to Manitoba Hydro in its recent consultation process about increased wildlife access and the particular impact that may have on moose. As seen in the original letter of commitment dated October 29, 2012, and the associated table, and the letter to Manitoba Conservation and Water Stewardship in February of 2013, mitigation measures to address this concern have been contemplated and enhanced over time, such as allowing vegetation management to allow wildlife corridors (or higher tree growth) to exist in specific small segments under the Transmission Line, thereby reducing lines of site for hunters and reducing the use of the Right-of-Ways by wolves.

Exhibits MH 63 and MH 108

Manitoba Hydro also responded to community feedback that major transmission line projects do not provide concrete benefits to communities by creating a Community Development Initiative. Approximately 60 towns, villages, municipalities, First Nations and NACCs are potentially eligible to share in funding of approximately $4 to $5 million per year for a ten year period. That Initiative will be finalized if a licence is received and reviewed at the end of the ten years.

Evidence of Deirdre Zebrowski, October 3, Page 482

With respect to biophysical components, by way of example, feedback received with respect to the importance of certain bird types was incorporated into the selection of the VECs. There are over 400 bird species in Manitoba alone and this had to be narrowed down considerably. Concerns with respect to items such as bird collisions were incorporated into the mitigation measures through the use of bird diverters, the establishment of buffers in sensitive areas, and restrictions on construction (where possible).

Evidence of Robert Berger, October 29, Page 2226, Page 2241, Pages 2246 – 2247, and Pages 2254 - 2256

In the area of invertebrates, amphibians and reptiles, information with respect to garter snake hibernacula was received directly from the ATK workshop in Barrows and with respect to frogs from the Pelican Rapids ATK workshop. This was incorporated into the technical report and used in the determination and assessment of VECs.

Evidence of Kurt Mazur, October 29, Page 2276

ATK was incorporated into the wildlife biologist's work on mammals. By way of example, information obtained from interviews and workshops provided areas where the American Marten is found, which helped validate some of the assumptions made with respect to high quality habitat.

Evidence of Doug Schindler, October 30, Page 2325

It was also learned from the ATK workshops and self-directed studies that there were 156 occurrences of environmentally sensitive sites important to communities in the 4.8 kilometre wide corridor studied. That information became particularly important in the development of appropriate mitigation measures. That information also informed the decision of route selection in a number of instances, including on one of the routes analyzed in the latter route revision process.

Evidence of Virginia Petch, October 30, Page 245

Evidence of Pat McGarry, October 4, Page 687 and March 4, Page 5917

Manitoba Hydro has also heard about the interest from Aboriginal persons to benefit from the Project in terms of employment and business opportunities. As described, there are numerous opportunities being explored for employment with Manitoba Hydro, particularly in its apprenticeship programs. Hiring preferences have been incorporated into both the Burntwood Nelson Agreement and the Transmission Line Agreement. Ongoing discussions are taking place with various Aboriginal groups to contract out certain work, including but not limited to work related to clearing and camp operations.

Evidence of Glenn Penner, October 5, Page 1018, and March 12, Pages 6790 - 6791

Evidence of Rob Elder, October 5, Pages 1019 - 1020

In summary, Manitoba did respond in a constructive and practical way. Despite the wealth and volume of the information provided through the various sources, Manitoba Hydro was able to make good use of the information gathered to determine the appropriate VECs to be studied, to make the best possible routing choices, and to select the most effective mitigation measures so as to minimize the impact on the environment.

2. DID MANITOBA HYDRO IDENTIFY THE CORRECT VALUED ENVIRONMENTAL COMPONENTS ("VECS") AND THE RIGHT ISSUES?

Manitoba Hydro had the monumental task of trying to balance the needs of numerous stakeholders with a wide variety of environmental considerations when coming up with a Final Preferred Route. It was not able to look at route planning from a singular perspective, as others with particular special interests have done.

Manitoba Hydro followed a set of general guidelines for routing, including identification of routing opportunities and the establishment of avoidance criteria, so as to minimize the impact of the Project on the environment.

Evidence of Pat McGarry, October 2, Pages 337 - 343

Manitoba Hydro took advantage of routing opportunities, compatible with environmental protection. By way of example, it:

- used existing linear corridors or sites, where possible, for the sake of VECs such as the boreal woodland caribou in the Wabowden area;
- used existing road allowances, where possible;
- routed on the half mile line, where possible (approximately 32% of the route in agricultural Manitoba); and
- used land already purchased by Manitoba Hydro, where available, such as at the proposed site for the new Riel Converter Station.

Evidence of Jim Nielsen, October 30, Page 2477 – 2480

Evidence of Pat McGarry, October 2, Page 343

Manitoba Hydro also utilized the principle of avoidance – avoid where possible – to further protect the environment and minimize the impact of the Project. It avoided such things as:

- communities and heavily populated areas;
- reserves and Treaty Land Entitlement selections;
- water crossings; and

- Provincial parks, designated protected areas, areas of special interest and wildlife management areas.

Evidence of Pat McGarry, October 2, Pages 340 - 343

This approach is a reasonable and practical one, as the impacts of routing through those areas could be devastating.

In farming and rural areas, the route selected avoided such key things as:

- communities;
- airports;
- dwellings;
- farm buildings;
- farm yards;
- intensive livestock operations;
- row crop and intensive annual cropped areas;
- lands under irrigation or pivots; and
- encumbered land such as Treaty Land Entitlement selections.

Evidence of Pat McGarry, October 4, Pages 745 – 746

Evidence of Jim Nielsen, October 30, Pages 2469 – 2472, Page 2489

Based upon direct feedback from farmers, in-field placement and diagonals were also avoided to stay away from houses, barns and farm yards.

Evidence of Jim Nielsen, October 30, Page 2477 – 2480

Through this type of route selection process, opportunities for routing with minimal negative impact were maximized and constraints were avoided to the degree possible. The Project was able to avoid key VECs, such as the majority of boreal woodland caribou ranges, and only took out of production approximately 17.8 hectares of arable land. Further, only 60 square kilometers of undisturbed Crown land was used, so as to minimize the impact on harvesters.

Evidence of Cam Osler, October 29, Page 2190

Answer to Undertaking given at Page 2489 on October 30

Manitoba Hydro assembled a large team of highly qualified experts from all areas of environmental study and asked them to come together as a team to review the five eco-zones and seven eco-regions in depth and to determine the appropriate VECs.

The experts conducted field studies, carried out literature reviews, did habitat modeling, reviewed the input and information gathered from the EACP and ATK workshops, all in order to determine the appropriate VECs.

Evidence of Cam Osler, October 29, Page 2194

Not all environmental elements can be studied. In assessing the environmental impact on a project, you must find pathways for its effects on a VEC.

Evidence of Cam Osler, October 29, Page 2171 – 2172, Page 2196

There are hundreds of possible VECs but this team, using its combined expertise and experience, was able to narrow it down to 67 VECs within 28 different categories (46 bio-physical and 21 socio-economic).

Evidence of Cam Osler, October 29, Pages 2188 - 2189

The tremendous scope of this task can be demonstrated by looking at a few examples, starting first with the bio-physical.

As described earlier, there are over 400 bird species. Birds are ecologically and socially important and a strong component of the biodiversity in Manitoba. Those species had to be placed in six major groupings and distilled to the most vital by examining their domestic, cultural, recreational and community importance, their population status, and whether they were a species at risk – threatened or endangered.

Evidence of Robert Berger, October 29, Pages 2230 – 2231; Page 3326

When examining terrestrial ecosystems and vegetation in 2010, there were a number of eco-regions, 21 vegetation cover types, and 457 plant taxa identified. Over 29 locations for species of concern were observed and over 80 species of plants of traditional value found.

Evidence of Kevin Szwaluk, October 29, Page 2267

Mammals were studied by a wildlife biologist and his team and a number of different factors were considered:

- Mammals of importance to people for reasons such as hunting, trapping, cultural significance;
- Mammals considered of importance under current law, such as protected or critical habitats, or rare or endangered species;
- Keystone species that are critical in maintaining the structure of an ecological community impacting other species (such as beaver);
- Umbrella species that reflect the broad habitat requirements for many species (such as moose); and
- Indicator species that are indicators of a particular habitat niche (such as elk).

Evidence of Doug Schindler, October 30, Pages 2303 – 2304; Page 3325

From that analysis, a list of VEC species was developed, namely caribou, moose, American marten, beaver, elk, wolverine and grey wolf as a linkage species.

Evidence of Doug Schindler, October 30, Pages 2304 – 2305

Moose were selected as a VEC due to their importance for rights-based hunting and recreational hunting. They are particularly important to First Nations and Métis for personal community sustenance.

Evidence of Doug Schindler, October 31, Page 2639

Literature reviews were undertaken, government and historical data were reviewed including fur production records, field data was collected, and habitat modeling, surveys and monitoring were carried out, all to ensure the proper VECs were identified and the most appropriate route selected. Monitoring was carried out with the assistance of local trappers.

Evidence of Doug Schindler, October 30, Pages 2312 – 2314; Pages 2317 - 2319

The effects on the VEC species were examined, taking into account such concerns as overharvesting, habitat loss, alteration or fragmentation, proximity to linear developments, and sensory disturbance.

Evidence of Doug Schindler, October 30, Pages 2312 – 2314

A Socio-Economic Impact Assessment was also carried out to determine the appropriate VECs related to this Project. Such an assessment examines the effect of the Project on people in the vicinity who are part of the existing socio-economic environment. It was recognized that changes in both physical and bio-physical environment can affect the well-being of people, lands and the resources they use, and can affect their ways of life.

Evidence of Elizabeth Hicks, October 30, Page 2356

21 socio-economic VECs were selected by the team, falling under the following categories:

- Land Use - 6;
- Resource Use – 7;
- Economy - 1;
- Services - 2;
- Personal, Family and Community Life - 3; and
- Culture and Heritage - 2.

Evidence of Elizabeth Hicks, October 30, Pages 2356 – 2357

Chapter 8 of the EIS

Through the study of those VECs and the primary concerns surrounding them, additional areas to avoid were:

- Significant historical and cultural sites and burial grounds; and
- Key areas of concern for certain species both spatially and temporally such as habitats, nesting sites, calving areas, food sources, nesting, calving and denning periods.

In order to ensure that the right issues in agricultural Manitoba were identified and addressed, an agricultural specialist was retained. Information on soil types was gathered, both existing and new aerial photography was accumulated and assessed, the route was flown and driven several times to ground truth and determine key impediments, and the lines were developed over one and a half years of intensive work.

Evidence of Jim Nielsen, October 30, Pages 2467 – 2468

Extensive areas of similar soil types and high value cropland led to an initial selection of the shortest routes south of Winnipeg to minimize distance over these agricultural areas. While this makes sense from an agricultural perspective it is not always possible due to other considerations such as subdivisions and density of land development closer to Winnipeg.

Evidence of Jim Nielsen, October 30, Pages 2474 – 2476

Evidence of Pat McGarry, October 4, Page 766

Self-supporting structures were recommended to allow for farming operations to continue after tower placement, at an additional cost four to six times greater than guyed towers. This is much more difficult under guyed towers.

Evidence of Jim Nielsen, October 30, Pages 2481

In routing through agricultural areas, Manitoba Hydro used the relevant constraints and followed the general guidelines for routing.

EIS, Chapter 4, Pages 4-21 – 4-22

Evidence of Robert Berrien, November 19, Pages 5338 - 5339

Culture was selected as a single VEC, defined as a repertoire of behaviours and themes that identify the identity of a social group. It is described as a VEC in the EIS as it is an expression of the relationship between humans and the natural environment. The approach taken with respect to culture paralleled the methods and indicators identified by the UNESCO framework.

Evidence of Virginia Petch, October 30, Pages 2426 - 2427

Heritage resources were considered a VEC because they are a non-renewable resource. They are valuable for their archaeological, paleontological, cultural, pre-historic, historic, natural, scientific or aesthetic features. As of 2010, there were 5,012 registered heritage sites alone in the Project study area, including centennial farms, commemorative plaques, municipal and provincial sites, and archaeological sites.

Evidence of Virginia Petch, October 30, Pages 2435 - 2436

The importance of culture and heritage resources was also seen in the assessment of the route revisions requested by MCWS. Their existence and importance affected Manitoba Hydro's assessment of the Alternate Final Preferred Route in one section and their preference between the Final Preferred Route and Alternate Final Preferred Route.

Evidence of Pat McGarry, March 4, Pages 466

Where there was a pathway to potential health effects, and where concerns were expressed, Manitoba Hydro conducted further assessment, including electric and magnetic fields and noise. A human health impact assessment was not considered appropriate or necessary based upon the nature of the Project and its potential effects on health. Precedents provided by the Participant's expert were not at all comparable or applicable – for example, one of the assessments looked into concerns with chemical carcinogens found in liquid hydrocarbons, while another dealt with effects from an aluminum smelter operation.

Evidence of Dr. Lee, November 15, Pages 5102 - 5106

Through this extensive Site Selection and Environmental Assessment approach, and with the assistance of experienced professional experts, Manitoba Hydro was able to recognize the key issues in routing and was able to identify the most crucial VECs potentially impacted by the Project.

3. ARE MANITOBA HYDRO'S CONCLUSIONS REGARDING THE SIGNIFICANCE OF IMPACTS SOUND?

The Project itself and the route chosen were designed to achieve reliability without significant adverse effects. The route and site selection process allowed for early integration of potential environmental and socio-economic issues and provided considerable opportunities to avoid adverse effects where feasible, and allows the assessment to focus on areas where there are concerns regarding potential for measurable cumulative effects on VECs.

Exhibit 59, Slide 10 and 14

Evidence of Cam Osler, October 29, Page 2192

The assessment considers pathways of effect of each Project component on each VEC.

Evidence of Cam Osler, October 29, Page 2196

MH-59, slide 33

When the VECs have been identified and the pathways of effect determined, the next step is to consider the direction and nature of the effect on the VEC. Is it positive, negative or negligible in direction? How large is it? What is its geographical extent? Of what duration is it?

Evidence of Cam Osler, October 29, Page 2196

The VECs for the Project were screened in this fashion by the team of experts to determine the direction of their effects. This screening process looked at duration, magnitude and geographical extent of effects on each VEC in detail. Where there were potentially significant residual effects additional criteria were considered (i.e., frequency, reversibility and ecological and societal importance).

Evidence of Cam Osler, October 29, Page 2199

For those VEC's affected by the Project, the assessment was VEC focused, looking at whatever is affecting the VEC. The VECs sustainability and sensitivity were examined. For example, is it a threatened species? Are the people affected vulnerable?

Evidence of Cam Osler, October 29, Page 2196 - 2197

Where there was a potential adverse effect on a VEC that could not be avoided through route selection, mitigation measures proposed and discussed by Manitoba Hydro staff and specialists were applied to minimize or eliminate potential adverse effects.

Evidence of Cam Osler, October 29, Page 2196

Where there was a measurable adverse effect that could not be addressed through mitigation measures, and where appropriate, compensation has been offered. Two such examples are the Landowners Compensation Policy and the Trappers Notification and Compensation Policy.

Evidence of Cam Osler, October 29, Page 2198

A formal policy has not been established for outfitters. This is not intended to minimize the legitimacy and importance of the businesses being operated. However, as compared to landowners and trappers numbering in the hundreds, there are only two outfitters which have come forward with potential claims. Years of history, and considerable records, exist with respect to the income earned and the impacts on both of those groups (i.e. landowners and trappers), such that a fair, reasonable and consistent policy can and was established. To the contrary, the claims of the outfitters have not yet been established and contain many uncertainties still need to be considered. Many, if not all, of the potential impacts on outfitters can be mitigated. Manitoba Hydro has said it will entertain their claims if, and when, they do occur. It is not in any way rejecting their position and Manitoba Hydro will review each such claim on a case by case basis as they arise.

Evidence of Pat McGarry, March 12, Page 6800 - 6805

Exhibit WPG 17

The residual effects significance evaluation was undertaken after consideration of mitigation. Regulatory significance can potentially occur where there is still a residual adverse effect after mitigation. Determining the regulatory significance of the residual effects required specialist opinions on the effect (e.g., magnitude, duration, geographic extent) and the probability of the effect actually occurring, the degree of certainty in our present knowledge of the subject and the expected results of mitigation measures, continued follow-up monitoring and, in some cases, the development and implementation of follow up adaptive management plans to address uncertainties.

Manitoba Hydro's conclusions as to significance were based upon the extensive work done by numerous experts, all of whom prepared detailed technical reports, and most of whom attended at the hearing to be questioned on their work.

Once residual Project effects were identified, a cumulative effects assessment was carried out. During this hearing the matter of CEA framework and approach has received considerable attention. Appendix A of this Argument accordingly provides a summary regarding the CEA approach and clarifications on various specific issues. An overview of relevant points is provided below.

The cumulative effects assessment ("CEA") for the Project reflects current good practice and follows a method in alignment with the *Cumulative Effects Assessment Practitioners Guide* ("the Guide") prepared by the Cumulative Effects Assessment Working Groups for the Canadian Environmental Assessment Agency.

Evidence of George Hegmann, March 12, Pages 69 - 70

Evidence of Cam Osler, November 22, Page 5818

Appendix A

The CEA prepared in support of the Bipole III Project regulatory EIS filing follows a "project centric" approach, within which also lies the concept of the "residual effects trigger" as discussed in this hearing. CEA was conducted only for those VECs for which the Project results in a likely measureable adverse residual effect. This approach examined potential effects by the proposed Project on selected VECs, and through a cause-effect analysis evaluated significance of Project residual effects. This approach did not assess VECs unless they are affected by the Project, and also did not assess VECs where such effects of the Project are not adverse or measureable, and reflects understanding that Project contribution is critical to allow one to make judgment on the Project's effects and hence its acceptability. The Guide and the Canadian Environmental Assessment Act ("CEAAct") support this as a fundamental basis of assessment. This approach was the practice adopted in the 2009 New Nuclear-Darlington project CEA, and in the CEAs used by BC Hydro in all of its recent northern transmission line project assessments. As such, the Bipole III CEA using this approach reflects current and best practice and is not deficient in regards to VEC selection and assessment of effects.

Evidence of C. Osler, February 22, Pages 5818-5823; 5861-5863

Evidence of G. Hegmann, Feb 18 Rebuttal, Page 2

Evidence of G. Hegmann, March 12, Pages 71-76

Appendix A

The words "cumulative effects assessment" have often been used interchangeably to mean two different things. A regional or strategic planning CEA has nothing to do directly with any one project application for regulatory review. Notwithstanding the potential benefits of having available a regional or strategic planning CEA in order to set context and (potentially) thresholds for overall effects on certain VECs in the region, the lack of such regional CEA studies does not in itself constitute deficiency in a CEA project assessment. Examples of where such regional or strategic CEA have been prepared, such as the oil sands region, confirm that such CEAs are supported by government responsible for overall resource and regional planning in the affected area. Dr. Noble and Dr. Gunn agreed that "regional strategic environmental assessment is ultimately the responsibility of government". To date, no such overall regional or strategic CEA has been prepared by government for the various regions affected by the Bipole III Project.

On this matter, the Bipole III CEA also complies fully with the Scoping Document (Section 8), i.e., it is based on CEAA guidelines as well as best and current practices in that it is required only to take into consideration any relevant regional and strategic environmental assessments available at the time the Bipole III EIS was prepared (and no such assessments were in fact available).

Evidence of G. Hegmann, March 12, Pages 6857-6859, 6887-6893

Evidence of Dr. Noble & Dr. Gunn, November 15, Pages 4963-4964

Evidence of C. Osler, November 22, Pages 5006-5007

Chapter 8 considered the cumulative effects of past and current projects when assessing the effects of the Project on each VEC. Chapter 9 built on the assessment in Chapter 8 by including a focus on future projects/activities where there is spatial or temporal overlap with residual adverse effects from the Project.

Exhibit 59, slides 17, 34, 46 to 56

All VECs with measurable adverse residual effects of the Project were carried forward for further analysis and consideration. Of the 67 biophysical and socio-economic VECs considered in the EIS effects assessment (Chapter 8), 64 VECs were considered in the cumulative effects assessment (Chapter 9). Two of the initial 67 VECs examined in Chapter 8 of the EIS were not examined in Chapter 9 due to the absence of a detectable adverse residual effect from the Project (Dakota Skipper and Groundwater Quality), and only one was not examined due to a residual positive effect (Economic Opportunities).

The CEA in Chapter 9 then screened VECs based on the geographic extent, magnitude and duration of effects in order to focus on key VECs where there was potential for non-negligible cumulative adverse effects. The CEA carried out in Chapter 9 for the remaining 64 VECs resulted in more detailed analysis of four VECs which were subject to further detailed analysis and consideration: Caribou (Wabowden herd), Community Services, Travel and Transportation and Public Safety (Gillam). Two further VECs were subject to more extensive consideration in the February 28 Supplemental Assessment Report: Moose (in GHA 14 [Moose Meadows] and GHA 19A and 14A) and Culture (in area of GHA 19A and 14A).

Response to CEC/MH-VI-347

Exhibit MH 59, Slides 7, 8, 16, 17, 33, 34, and 46 - 56

Evidence of Cam Osler, October 29, Pages 2172 – 2177, 2182 – 2184, Page 2191, Pages 2196 – 2197, Page 2199, and Pages 2206 – 2214

Evidence of Cam Osler, November 22, Pages 5861 – 5867

Evidence of George Hegmann, March 12, Pages 113 - 116

In carrying out the cumulative effects assessment, the Corporation:

- Determined if the Project would have an effect on the VEC;
- If a negative effect was demonstrated, determined if the incremental effects acted cumulatively with the effects of other actions (past, present and sufficiently known future ones);
- Determined if the combination of Project effects with other effects was going to cause a significant change now or in the future in the characteristics of the VEC after mitigation; and
- Tested whether the Project was incrementally responsible for the adverse effect and to what degree.

The cumulative effects assessment is not an assessment of past or future projects. Rather, it is the description of the overall, or cumulative, effects on the VEC and the extent to which Project is expected to be incrementally responsible for adverse effects. It examines potential overlaps of those effects with those from the Project on each VEC.

The assessment considers VEC context in light of effects from all sources - as addressed in detail in Appendix A to this Argument.

Three VECs with potentially significant effects were identified related to effects during the construction phase of the Keewatinoow Converter Station:

- Public safety in the Gillam area as a result of potential worker interaction;
- Traffic concerns to and from Gillam; and
- Community services such as hospitals and policing in the Gillam area.

Evidence of Elizabeth Hicks, October 29, Page 2386

Given the concerns identified, the proposed mitigation measures were revisited for those specific VECs. Additional work was done with both subject matter experts and members of the communities in and near the Gillam area and enhancements to the mitigation measures were proposed. Project plans and mitigation measures designed to minimize those effects include:

- The establishment of both start up camp and a main camp several kilometers away from the Town of Gillam, equipped with:
    - lodging and meals free of charge;

    - a separate ambulance service;
    - fire truck;
    - first aid building (in the case of the main camp);
    - a shuttle bus;
    - lounge and recreational facilities; and
    - access gates to allow for tracking and monitoring.
- Cultural awareness training of Hydro staff and contractors;
- Strictly enforced rules and security with respect to discipline, impaired driving and intoxication;
- Ongoing awareness initiatives regarding safe driving practices;
- Traffic signage on the access road and a traffic monitoring program; and
- Regular communication between Manitoba Hydro and the RCMP.

Evidence of Elizabeth Hicks, October 30, Pages 2380 - 2383

Residual adverse effects were also identified with respect to boreal woodland caribou. Thresholds for disturbance were reviewed that are available and provided in the National Recovery Strategy for Boreal Woodland Caribou in Canada. Caribou are a threatened species under both Provincial and Federal legislation and there are now in place both a national caribou recovery strategy and a Provincial one. Manitoba Hydro participates on three regional caribou committees and embarked upon a research project to contribute to caribou conservation in the future.

Evidence of Jim Rettie, October 31, Pages 2578 – 2579

Evidence of Mr. Schindler, MH-73

Evidence of Mr. Schindler, October 31, Pages 2623-2624

Manitoba Hydro convened an expert panel to conduct a formal risk assessment of the potential threat to woodland caribou from the Project. The assessment categories included forage loss and degradation, range fragmentation, predation, pathogens and direct mortality from humans.

Evidence of Jim Rettie, October 31, Page 2557 and Pages 2579 - 2580

Recommendations from the panel included a collaring and monitoring program to identify critical local range components, and a monitoring of local populations to determine the effects of linear disturbances on predation.

Evidence of Jim Rettie, October 31, Pages 2580 - 2582

The recommendations of the panel were implemented – a collaring and telemetry study was conducted, aerial surveys were carried out, habitat modeling took place, and new range maps created. The results of this detailed analysis were then used in the route selection to avoid the majority of ranges and habitats and to develop mitigation measures.

Evidence of Jim Rettie, October 31, Pages 2582 – 2588; Page 2591

Evidence of Doug Schindler, October 31, Page 2593

The majority of potential residual adverse effects on boreal woodland caribou were mitigated through this extensive study and analysis, and through the use of the pre-project monitoring, mainly through avoidance and the paralleling of existing infrastructure. There is not expected to be a decline in population as a consequence of increased predation due to the Bipole III Project.

Evidence of Jim Rettie, October 31, Page 2635

The AFPR changes in the Wabowden area reduced scientific uncertainty and concern regarding the potential residual effects of the Project on the Wabowden boreal woodland caribou evaluation range and increased the confidence in the prediction of residual effects and the overall assessment of significance for the boreal woodland caribou VEC

Exhibit MH-113

Evidence of Doug Schindler, March 4, 2013 pages 5983-5988

The use of thresholds is challenging as there are not many currently in existence. Not using thresholds does not necessarily represent a deficiency, so long as efforts are demonstrated to identify and apply if available.

Evidence of George Hegmann, February 18 Rebuttal, Pages 2

During the course of the hearing, and as new information became available, moose became more prominent as a VEC, necessitating further work and study, and a further cumulative effects assessment.   It had been determined at the time the EIS was drafted that the potential residual effects on moose of the Project, as a linear development, were not significant.

Evidence of Doug Schindler, October 30, Page 2312 – 2314

Due to additional information being provided by the Province and further concerns being brought forward on the decline of the moose population in certain Game Hunting Areas (GHAs) along the proposed route, there was a re-consideration of the route by Manitoba Conservation and Water Stewardship (MCWS) in GHA14 and in GHA19A/14A. Further field studies and review work were done by Manitoba Hydro to conduct an environmental assessment on the route alterations proposed by MCWS and to determine what, if any, effect the Project would have on the environment in those regions.

The February 2013 Supplemental Assessment concluded that with either the AFPR or the FPR for the HVdc transmission line component of the Project and mitigation as described in Chapter 6, the cumulative effects of the Project in combination with other past, current and future projects are not expected to result in any significant residual adverse effects on moose.

With respect to moose:

- In GHA 14, he AFPR crosses a larger amount of higher value moose habitat than the FPR, but does not change the significance evaluation from the EIS, as such either segment is viable.
- In GHA 19A/14A the AFPR has potentially significant issues (with respect to culture), so enhanced mitigation was proposed to allow re-adoption of the FPR while reducing or eliminating access issues to moose habitat.

Exhibit MH-113

March 4, 2013, page 5988-6037

The proposed AFPR change in the GHAs 19A and 14A areas will move the HVdc line construction and ongoing operation into a culturally sensitive area that is avoided by the FPR, and result in potentially significant adverse residual effects on the culture of Camperville, Pine Creek First Nation and Duck Bay. Aside from avoiding this area through routing the HVdc transmission line elsewhere (as was achieved with the FPR in the original EIS), Manitoba Hydro is not currently aware of mitigation measures likely to alleviate adequately these expected adverse residual effects on culture from the AFPR route change in the GHA 19A/14A area. Overall, the assessment concludes that the residual adverse effect of the AFPR in this area on culture is “not significant”; however, uncertainty is noted as to whether the ongoing adverse effect will remain moderate in magnitude and medium term in duration. The assessment of the FPR in this area had concluded that the residual adverse effects of the FPR on culture is not potentially significant.

Exhibit MH-112

Evidence of Virginia Petch, March 4, 2013 page 5972-5982

4. GIVEN THAT THE ROUTE BY THE ELECTORAL DECISION OF THE PEOPLE OF MANITOBA IS TO BE A WEST ROUTE, HAS MANITOBA HYDRO SUCCESSFULLY BALANCED ALL OF THE COMPETING RESTRAINTS OF SUCH A ROUTE?

It was acknowledged by Manitoba Hydro that one of the most common themes received during the consultation process pertained to the decision to route Bipole III on the west side of the Province, rather than on the east side.

Evidence of Pat McGarry, October 3, Pages 653 – 654

However, Manitoba Hydro cannot address that concern, based upon the decision reached by the Government of Manitoba in that regard in September of 2007.

Manitoba Hydro was then faced with the challenge of routing around, and in some cases, through areas of importance to particular groups, such as:

- Treaty Land Entitlement and reserve lands;
- Lands used for harvesting and domestic resources;
- Other lands of cultural and heritage importance;
- Intensive agricultural areas;
- Protected regions, Provincial Parks and Wildlife Management Areas;
- Critical habitats; and
- Regions already heavily developed with hydro, forestry and other projects.

Selecting a route on the western side of the Province was exceedingly challenging, given all of the impediments and the numerous competing interests, and given the distance the route had to cover – almost 1400 kilometers. As even Mr. Berrien conceded:

> "You guys had a huge job. I mean, it went up from all the way up in the shield all the way down into the Assiniboine flats and clay. It was a huge profile of land for sure."

Evidence of Robert Berrien, November 19, Page 5343

Focus was on the VECs relevant to the area being assessed. Where the VEC was not relevant to the section being evaluated, it was given a low or zero rating in the route selection matrix.

Evidence of Pat McGarry, October 4, Page 780

The task of balancing those interests, which were often at odds with each other, was a monumental one. During the evidence provided by Mr. McGarry and Mr. Dyck, they were able to demonstrate and depict visually the competing interests in one small section of the route through the display of the bottle neck map found in Chapter 8. The overlap in concerns and issues was staggering.

The extensive Site Selection and Environmental Assessment process, it has attempted to balance those competing interests and the various constraints revealed through both that process and through the EACP. Its use of numerous subject matter experts and a team approach was important to obtaining that balance.

Many of the remaining complaints raised by Participants and presenters with respect to aboriginal engagement arise out of issues with the Crown's constitutional duty to consult with First Nations and representatives of other Aboriginal communities and persons, including the MMF, and the alleged lack of progress on that Crown Consultation Process. With respect, issues arising out of that process are beyond the scope of this hearing, as the duty to consult has not been delegated to Manitoba Hydro. Further, environmental assessment in Manitoba is not designed to assess the impact on treaty or Aboriginal rights.

As already decided in a preliminary motion by Peguis First Nation, "it is not the Commission's job to tell the Crown how to conduct its business. This includes the content, the process and the timing of the Crown's consultations." It also stated that "in the absence of any legal authority which would require the Commission to consider the nature and adequacy of Crown consultations or of direction from the Minister in the Terms of Reference, the panel is of the view that no such obligation exists."

Decision of the CEC dated August 31, 2012

Concerns remain with respect to the Technical Advisory Committee ("TAC") process and the volume and substance of comments received from subject matter experts on that Committee. Again, those concerns cannot be addressed by Manitoba Hydro.

Evidence of Warren Mills, March 6, Pages 6443 - 6445

Throughout the hearing, we have heard from some landowners and farmers that they remain unhappy with the route selected and the residual effect the Project will have on their operations. The alternatives to the Project put forward by the Bipole III Coalition on their behalf are not acceptable from a reliability and cost perspective and cannot be implemented. To move the route elsewhere in southern Manitoba does not eliminate the concerns.

In the view of Mr. Nielsen, even with additional study and analysis, a better route through intensive agricultural land could not be found. It was reasonable routing which tried to avoid people, farm yards, residential areas and the like, and reduced diagonals. Moving the line elsewhere would only move the line to similar soil types and to someone else's farming operation.

Evidence of Jim Nielsen, October 30, Pages 2485 – 2487

The Bipole III Coalition introduced some potential alternate routing with agricultural Manitoba through Mr. Berrien. However, as he conceded, the "devil is in the detail". Many of his suggestions ignored routing constraints or impediments that were in existence, such as houses and shelter belts. There can be no substitute for the hours worked, and the kilometres travelled, in establishing a route that balances the needs and wants of the many landowners in the vicinity with the technical requirements of the Project.

Evidence of Robert Berrien, November 19, Page 5363 and 5365

In the final analysis, only 17.8 hectares of land will potentially be taken out of production as a result of tower placement, a tremendous feat given the length of the route and the necessity to go through western Manitoba.

Answer to Undertaking given at Page 2489 on October 30

Manitoba Hydro does, though, recognize and acknowledge the effect on such landowners. For that reason, it has a Landowners Compensation Policy to attempt to address the financial impact and has revised it over time to continue to address concerns that have been raised.

That program contains four components, made up of both one-time payments and "real time" payments to address specific impacts as they arise.

- Land compensation equivalent to 150% of the market value of the land taken for the easement, as compared to land acquired by way of expropriation (market value only).

Evidence of Curtis McLeod, October 30, Pages 2496 – 2500; Page 2505; Page 2519

- One-time structure impact compensation for the crop loss and related losses associated with the extra time and effort required to go around each tower, taking into the account the dominant land use in the past.

Evidence of Curtis McLeod, October 30, Page 2498

- Construction damage compensation negotiated post-construction for any kind of damage to property such as crops, land, or equipment

Evidence of Curtis McLeod, October 30, Pages 2497

- Ancillary damage compensation for direct or indirect impacts to the use of the property, such as impacts caused by an inability to aerial spray in one year; claims can be made by both landowners with towers on their property and by landowners in the vicinity of towers if they have been impacted.

Evidence of Curtis McLeod, October 30, Pages 2500 – 2501; Page 2506; Page 2520

In the one example provided – for one mile of right of way containing three or four towers and causing a minimal loss of cultivated land, a landowner would receive $111,000 of compensation.

Evidence of Curtis McLeod, October 30, Page 2502

It is not a "one size fits all" solution and has been customized to some degree. It will address individual impacts and can certainly be adapted over time to deal with unique issues that arise over time. It offers an upfront payment immediately and is also on par or better than that provided by electrical utilities in neighboring Provinces.

Evidence of Curtis McLeod, October 30, Page 2502; Page 2505; Page 2520

While annual payments have been suggested, *Expropriation Act* does not allow for annual payments in this regard, as conceded by Berrien.

Evidence of Robert Berrien, November 19, Pages 5260 - 5261

Another competing interest raised during the hearing is the conflict between blueberry harvesters and the Corporation's need to clear vegetation and manage it into the future. Although the experts have indicated that blueberries do better after disturbances such as fire or other clearing, further analysis has been done to address the concerns and minimize the conflict between these competing interests. Significant dollars have been expended on research and development, which includes research into blueberries.

Evidence of Kevin Szwaluk, October 29, Page 2266, Page 2270, and Page 2275

Evidence of James Matthewson, November 8, Page 4046

Assurances have been provided that no herbicides will be used during the construction process and its application later will be targeted, single plant applications. In many areas, construction will be done in the winter to ensure no damage is done to growing plants. Sensitive areas can be flagged during construction to ensure they are not disturbed and buffer zones established to address community members' concerns. This is yet another example of the attempts by Manitoba to find balance.

Evidence of Glenn Penner, March 12, Page 6786

Evidence of Wayne Ortiz, March 12, Page 6810

Routing through lower quality pasture land was seen as a routing opportunity and selected as the Alternate Final Preferred Route in the area of Moose Meadows through a bison ranch, thereby minimizing the environmental impact on moose and staying further away from the community of Pine Creek First Nation. However, this attempt to balance competing interests still has not addressed the visceral concerns of PCFN due to the incorrect perception that bison ranch operators could potentially receive compensation from Manitoba Hydro.

Evidence of Warren Mills, March 6, Page 6482 - 6483

Evidence of Pat McGarry, March 12, Page 6806

Through consultation with government resource managers, several suggestions were made in regard to routing which were adopted. For example a salt spring near Red Deer Lake was avoided and routing through Wildlife Management Areas minimized. The Round 4 consultation on the PPR also resulted in a number of route adjustments to adapt to specific landowner requests related to tower placement, irrigation and fence lines. An adjustment was also made to the PPR for proximity to a waterfowl area

Appendix 7B Chapter 7 EIS

The participation and contribution of many interested people and groups has helped locate a major transmission line project in a sustainable manner in a very large and diverse biophysical and socio-economic environment. The FPR (with adjustments) represents the compilation of many technical studies and the collective input of many stakeholders leading to a project route that has no significant impacts after mitigation and follow-up.

5. CAN MANITOBA HYDRO MANAGE THIS PROJECT RESPONSIBLY, PROFESSIONALLY AND SUCCESSFULLY GOING FORWARD?

Manitoba Hydro has developed an Environmental Protection Program which provides the framework for the implementation, management and monitoring of the environmental protection measures that are deemed necessary and important to the environment as the Project proceeds. Manitoba Hydro has made a written commitment to over 600 mitigation and monitoring measures designed to manage this Project responsibly professionally and successfully going ahead and to protect the environment as it moves forward.

Evidence of James Matthewson, November 8, Pages 4052 - 4053

The draft Project Environmental Protection Plan has been developed, but only after:

- a comprehensive review of its two most recent major projects (Wuskwatim Project and Riel Sectionalization) for lessons learned;
- a detailed literature review;
- a review of other North American Environmental Protection Plans for similar projects; and
- interviews with other utilities to gain from their experiences.

Evidence of James Matthewson, November 5, Pages 4050 - 4052

This demonstrates a commitment to using an Adaptive Environmental Management approach, one in which you plan, do, evaluate, learn, and adjust.

Evidence of James Matthewson, November 5, Pages 4117

The Environmental Protection Program has a number of key components which will also help Manitoba Hydro manage this Project responsibly professionally and successfully going forward, including:

- Monitoring Plans for both biophysical and socioeconomic elements;
- Management Plans for matters such as:
    - Access management;

    - Blasting;
    - Emergency preparedness and response;
    - Erosion protection and sediment control;
    - Rehabilitation/Remediation;
    - Vegetation; and
    - Solid waste/recycling;
- Environmental Protection Plans for construction, operations and maintenance, and decommissioning;
- A Heritage Resources Protection Plan;
- Inspection, Monitoring and Communication Programs;
- Continuing engagement of stakeholders;
- The use of the more innovative active Adaptive Environmental Management model;
- Use of a number of environmental officers/monitors and specialists with authority to inspect and monitor and, where necessary, shut down;
- Significant involvement of communities, including the hiring of local environmental monitors and community liaisons;
- Annual reviews and audits; and
- Annual Monitoring Reports hosted on the Manitoba Hydro website and submitted to MCWS.

Evidence of James Matthewson, November 8, Pages 4055 – 4117

One small example of this approach and commitment was provided by Dr. Petch as she described the many steps taken and the care exercised when two burial sites were discovered near the proposed Keewatinoow site. She described the considerable work done, in conjunction with Fox Lake Cree Nation, to protect and preserve these significant heritage resources, and to carry out further monitoring and work into the future.

Evidence of Virginia Petch, October 30, Pages 2444 - 2450

Manitoba Hydro is committed to a comprehensive Program of environmental protection. It is committed to engagement with communities, First Nations, the Métis, and regulators, and to their involvement in identifying/reviewing environmentally sensitive sites and corresponding mitigation measures throughout Program development. It is committed to being adaptive, to learning, and to evolving throughout the duration of the construction and operation of the Project. The Program and associated Plans have been designed to meet or exceed applicable government guidelines and industry best practices.

Evidence of James Matthewson, November 8, Pages 4117 - 4118

Evidence of Deirdre Zebrowski, October 3, Page 479

The Corporation has taken on the significant responsibility to ensure the Project is implemented with minimal effects on the environment and people. The Project and environmental protection only begin with licensing and, while it is end of the regulatory process, it is merely the start for Manitoba Hydro.

THE FINAL TASK BEFORE THE CEC

Manitoba Hydro takes the position that each of the 5 questions have been answered in the affirmative and, based upon the entirety of the evidence, this CEC can, in good conscience and with strong conviction, now recommend to the Minister that the Project be licensed.

Specifically, Manitoba Hydro is asking that the FPR be adopted as indicated in the original filing of the EIS on December 1, 2011, save and except for the following change found in the supplemental EIS filed January 28, 2013:

- The AFPR in the Wabowden area, as it reduces scientific uncertainty and concern regarding the potential residual effects of the Project on Wabowden woodland caribou evaluation range. Manitoba Hydro believes that mitigation measures can address the concerns of the mining interests.

With respect to GHA 14, Manitoba Hydro is of the view that both the FPR and the AFPR are acceptable based upon the environmental assessment, although the AFPR contains considerably more high quality moose habitat and will result in more challenging mitigation measures related to access along the AFPR.

Manitoba Hydro remains in support of the FPR for GHA14A/19A, because the AFPR may result in potentially significant adverse effects on the culture of Camperville, Pine Cree First Nation and Duck Bay.

The CEC's task, however, does not end with that recommendation. What conditions does it recommend be placed on that licence? What mitigation measures need to be put in place and what future monitoring is required?

The Corporation has committed to over 600 mitigation and monitoring measures so as to ensure that any possible anticipated residual effect is minimized. Those commitments are contained in a letter of commitment to the CEC dated October 29, 2012, and Manitoba Hydro recommends that those be adopted. They are detailed, extensive, and properly address any residual effects that have been caused by the Project. They also involve stakeholders extensively in future endeavours.

A requirement that the commencement of construction of Bipole III be subject to a "pre-condition", namely the successful negotiation of an agreement with a third party, such as suggested by the MMF and its expert, MSES, TCN, and others is not practical because it is not enforceable. There is no process or body, Court or government that can successfully compel two parties to "agree". If there is to be an agreement, the parties themselves have to negotiate it and conclude it. Just as judges have, continuously, declined to enforce "agreements to agree", they will be unable to compel a reluctant party to "agree" on any basis, be it assertions by the frustrated licence holder that the reluctant party is being unreasonable, or be it assertions by the third party that the licence holder is not negotiating in good faith or is not funding the third party's negotiation costs in a reasonable amount.

Transcript, October 19, Page 2122

Such a condition is also not appropriate in the context of an environmental hearing. This is not a hearing into the constitutional rights of the MMF or others. It is a hearing into the environmental impact on the Valued Environmental Components relevant to this Project.

The MMF has suggested that there is an obligation arising out of the Aboriginal Justice Inquiry Implementation Commission ("AJIIC") to negotiate an agreement or treaty with them prior to any natural resource development proceeding. With respect, the Bipole III Transmission Line Project is <u>not</u> a "natural resource development".

Manitoba Hydro also asks the CEC to carefully consider the practical application of any recommendation it is pondering in regard to Manitoba Hydro, and whether the contemplated recommendation can, in fact, be implemented by it. Although heartfelt and perhaps legitimate, many of the requests being made by the Participants are far beyond the scope and authority of Manitoba Hydro. Manitoba Hydro asks that any recommendations made be thoughtful, practical and well-explained.

Manitoba Hydro would like to thank the Clean Environment Commission, the Participants and the various presenters for their attentiveness, helpful input and insightful questions throughout the process. Manitoba Hydro has attempted to learn through this process, to adapt and respond to concerns expressed and the recommendations made, and to improve the assessment overall. A full environmental assessment is an iterative process and, as a result of the participation of all involved, the assessment process has been improved and the analysis of the Project more thorough. In the end result, the value of the hearing has been demonstrated and the end produce vastly improved. Manitoba Hydro will also take forward what it has learned from this experience and continue to improve upon its environmental assessments in the future.

APPENDIX A: SUMMARY RE: CUMULATIVE EFFECTS ASSESSMENT APPROACH

In response to issues raised by CAC and others during the hearing, Appendix A summarizes key points regarding the cumulative effects assessment approach and framework provided in the Bipole III Project EIS.

Compliance with *Cumulative Effects Assessment Practitioners Guide*

The cumulative effects assessment (CEA) for the Bipole III Project reflects current practice and follows a method in alignment with the *Cumulative Effects Assessment Practitioners Guide* (the "Guide"), prepared by the Cumulative Effects Assessment Working Group for the Canadian Environmental Assessment Agency (CEAAgency, 1999), and is therefore in compliance with the Guide and with good practice. Testimony to this was provided at the hearing by the lead author of the only current Canadian government guide available on CEA, the very Guide that Drs. Gunn and Noble themselves used and accepted as a benchmark. Mr. Hegmann's testimony on the matter of CEA current practice reflects his extensive and ongoing engagement in the authorship and/or management of project environmental assessments prepared for regulatory review and advice to governments and regulators, including for major linear pipeline projects in Canada that have relevance specifically to the CEA framework applicable to the Bipole III Project.

Evidence of G. Hegmann, March 12, Pages 6849-6850
Evidence of C. Osler, November 22, Page 5818

Clarifications on Specific Issues

1. **"Project-Centric Approach" and "Residual Effects Trigger" –** The CEA prepared in support of the Bipole III Project regulatory EIS filing follows a "project-centric" approach, within which also lies the concept of the "residual effects trigger" as discussed in this hearing, i.e., CEA was reviewed in Chapter 9 only for those VECs for which the Project results in a likely measureable adverse residual effect. This approach examines potential effects by the proposed Project on selected VECs, and through a cause-effect analysis evaluates significance of Project residual effects. This approach does not assess VECs unless they are affected by the Project, and also does not assess VECs where such effects of the Project are not measureable, and reflects understanding that Project contribution is critical to allow one to make judgment on the Project's effects and hence its acceptability. The Guide

and the CEAAct support this as a fundamental basis of assessment. This approach was the practice adopted in the 2009 New Nuclear-Darlington project CEA[2], and in the CEAs used by BC Hydro in all of its recent northern transmission line project assessments. As such, the Bipole III CEA using this approach reflects current and best practice and is not deficient in regards to VEC selection and assessment of effects.[3]

Evidence of C. Osler, February 22, Pages 5818-5823; 5861-5863
Evidence of G. Hegmann, Feb 18 Rebuttal, Page 2
Evidence of G. Hegmann, March 12, Pages 6851-6856

2. **"Baseline" reflects World Without the Project -** "Baseline" in the Bipole III Project CEA reflects the "world without the Project", and is an essential requirement in defining the incremental residual effects of the Project as required for a "project-centric" CEA[4]. As such, this "baseline" differs from some "earlier time" or "natural" condition where there are no effects from other projects and activities that are considered in the CEA. For regulatory applications assessing the effects of a specific project, use of existing conditions to represent a baseline is an acceptable approach. Such baselines include present and past human actions, to the extent they may be mapped and otherwise identified. The Guide supports this as a fundamental basis of assessment of best practice and, as such, the Bipole III CEA reflects current practice and is not deficient in regards to use of baseline. Defining the "baseline" as the "world without the Project" does not preclude the ability to consider "earlier time" or "pre-development" conditions for some VECs, where this is feasible and useful for the overall assessment of cumulative effects on a VEC relative to a acceptable threshold, e.g., earlier time periods were considered in the Bipole III supplemental CEA filings with regard to caribou and moose.

---

[2] Subject to the screening including VECs that were positively affected by the project.

[3] Mr. Hegmann discussed in his rebuttal and testimony that Dr. Noble and Dr. Gunn do not agree with the project-centric process followed in the Bipole III CEA and instead advocated an "ecosystem or ecologically or VEC based" approach based on health of ecosystem. It needs to be noted that a project-centric approach as recognized in current CEA practice and the Guide does not in any way mean that the CEA analysis does not also focus, where relevant, on the VECs themselves that are affected by the Project, including the context for the VEC absent and with the Project, and the sustainability of the VEC due to all factors affecting it, e.g., see Exhibit MH-59, slide 34 and related testimony of Mr. Osler. See also clarification #4 in this Appendix A.

[4] The concept of "non-static" or "evolving" baselines as discussed in the hearing recognizes the possibility that baseline conditions (i.e., the world without the Project) may change in the future due, for example, to natural phenomena, such as wildlife or climate change. Discussion of these issues does not affect the fundamental point that the Guide supports use of existing baseline conditions in CEA, and that this definition of "baseline" does not preclude consideration of other information for a specific VEC when relevant and feasible.

Evidence of G. Hegmann, Feb 18 Rebuttal, Page 2
Evidence of G. Hegmann & C. Osler, March 12, Pages 6896-6901

3. **All VECs with detectable adverse residual effects of the Project are included in the CEA -** Contrary to the evidence of Dr Gunn and Dr Noble asserting that the CEA in Chapter 9 of the Bipole III EIS looked only at VECs determined in Chapter 8 to have significant adverse effects from the Project[5], the Bipole III CEA in Chapter 9 examined all VECs (namely 64 VECs) with detectable adverse residual effects of the Project as determined in Chapter 8, and, as such, did ***not*** look only at VECs determined in Chapter 8 to have significant adverse effects from the Project. Only two of the initial 67 VECs examined in Chapter 8 were not examined in Chapter 9 due to the absence of a detectable adverse residual effect of the Bipole III Project, and only one VEC examined in Chapter 8 was not examined in Chapter 9 due a residual positive effect. As a matter of record, this point was reviewed in detail in the response to *CEC/MH-VI-347*; further, review of Chapter 8 as well as the referenced interrogatory response confirms that in fact there were no VECs assessed in Chapter 8 to have 'significant adverse effects from the Project."

   As an additional related point of clarification, the Bipole III CEA includes Chapter 8 as well as Chapter 9. As stated in the EIS, VEC assessments in Chapter 8 in each instance considered the cumulative effects of past and current projects when assessing the effects of the Project on each VEC, i.e., the added CEA analysis of VECs in Chapter 9 focused on future projects/activities where there is spatial and temporal overlap with residual adverse effects of the Bipole III Project.

   The CEA carried out in Chapter 9 for the 64 remaining VECs resulted in more detailed assessment of four VECs (boreal woodland caribou in three ranges as affected by the HVdc

[5] This misunderstanding starts to occur around page 26 of the critique filed by Drs. Gunn and Noble, and permeates section 1.4 of Appendix A and reappears at page 39. The Chairman on March 12 at pages 6879-6880 noted that 'we had been led to believe that if there is no significant residual effect, then there's no need to go to the next step and do a cumulative effects assessment."

transmission line component, and three socio-economic VECs [namely community services, travel and transportation, and public safety] with regard to residual adverse effects from construction of the Keewatinoow converter station and associated facilities). Subsequent supplemental CEA analysis was provided separately for caribou (prior to the CEC hearing) and more recently for moose in western Manitoba (February 2013).

Response to CEC/MH-VI-347

Evidence of C. Osler, October 29, Pages 2182-2184, 2206-2214
Evidence of C. Osler, November 22, Pages 5861-5867
Evidence of G. Hegmann, March 12, Pages 6893-6896

4. **Assessment considers VEC context in light of effects from all sources –** Notwithstanding analysis of incremental effects of the Project on each VEC, the Bipole III CEA considers the current and expected future context of each assessed VEC (i.e., including the effects on the VEC of other past, current and future activities) and, where available, any VEC thresholds. In this regard, the CEA examines the extent to which VECs are already disturbed and/or stressed by past actions and changing conditions (e.g., boreal woodland caribou listed as Threatened under federal and provincial legislation) and, where relevant, reasonably foreseeable future actions (e.g., public safety cumulative effects for Fox Lake Cree Nation and Gillam community members during construction of Keewatinoow converter station, Keeyask Generation and Conawapa Generation projects). In this regard, the Bipole III EIS structure in Chapter 8 assesses the CEA of Project residual effects combined with effects of past actions and existing projects/activities, and in Chapter 9 assesses the extent to which the Chapter 8 CEA determinations are modified for any VEC by consideration of Project effects combined with effects of other projects and activities not yet examined in Chapter 8, i.e., other future projects and activities as listed in Chapter 9.

Response to CEC/MH-VI-347

Evidence of C. Osler, October 29, Pages 2172-2177, 2196-2197, 2206-2214

5. **CEA for Regional or Strategic Planning versus CEA for Project Regulatory Reviews –** The words "cumulative effects assessment" have often been used interchangeably to mean

two different things. A regional or strategic planning CEA has nothing to do directly with any one project application for regulatory review. Notwithstanding the potential benefits of having available a regional or strategic planning CEA in order to set context and (potentially) thresholds for overall effects on certain VECs in the region, the lack of such regional CEA studies or analytical approaches such studies may use does not in itself constitute deficiency in a CEA project assessment. Examples of where such regional or strategic CEA have been prepared, such as the oil sands region, confirm that such CEAs are supported by government responsible for overall resource and regional planning in the affected area, and Dr. Noble and Dr. Gunn agreed that "regional strategic environmental assessment is ultimately the responsibility of government". To date, no such overall regional or strategic CEA has been prepared by government for the various regions affected by the Bipole III Project.

On this matter, the Bipole III CEA also complies fully with the Scoping Document (Section 8), i.e., it is based on CEAA guidelines as well as best and current practices in that it is required only to take into consideration any relevant regional and strategic environmental assessments available at the time the Bipole III EIS was prepared (and no such assessments were in fact available).

The Guide also fully recognizes that regional "nibbling" effects of the type highlighted by Drs. Gunn and Noble and the "thousand cuts" imagery usually cannot be adequately dealt with on a project-by-project review basis, and that regional plans of the type discussed above (i.e., prepared by government) are required that clearly establish regional thresholds of change against which the specific actions may be compared.

Evidence of G. Hegmann, March 12, Pages 6857-6859, 6887-6893
Evidence of Dr. Noble & Dr. Gunn, November 15, Pages 4963-4964
Evidence of C. Osler, November 22, Pages 5006-5007

6. **Use of Thresholds in Bipole III CEA -** The Bipole III Project CEA uses thresholds to assist evaluation of significance where thresholds are available for VECs, e.g., CEA for woodland caribou. Absence of use of thresholds does not necessarily represent a deficiency, so long as efforts are demonstrated to identify and apply if available. The Guide does not support the view that the significance of a cumulative effect on a VEC cannot be assessed or commented

upon unless there is some established threshold for the affected VEC[6]. In this regard, the Bipole III CEA represents current practice and the Guide supports this view.

Evidence of G. Hegmann, Feb 18 Rebuttal, Page 2

7. **Reliance in CEA on future management measures associated with other projects -** The Bipole III Project CEA's reliance on future management measures associated with other future Manitoba Hydro projects is a pragmatic and realistic recognition of one part of the long-term solution of cumulative effects within a given region. As such, mention of future measures supported by future projects does not represent a deficiency given that reasonable efforts are committed to by Manitoba Hydro regarding effects management. In this regard, the Bipole III CEA represents current practice and the Guide supports this view.

Evidence of G. Hegmann, Feb 18 Rebuttal, Page 2

8. **Accidental events are not assessed in CEA -** The Bipole III Project CEA does not assess accidental events or malfunctions. As such, absence of such an assessment within this CEA does not represent a deficiency. There is no federal *guidance* that stipulates inclusion of assessment of accidents in a CEA[7]. Assessment of accidents, malfunction and upset events (AMUEs) is typically done separately within a regulatory application (Chapter 8, Section 8.4 of Bipole III EIS) due to the very different nature of such effects (compared to routine project effects) and the low likelihood (rarity) of such effects. In this regard, the Bipole III CEA represents current practice and the Guide supports this view.

Evidence of G. Hegmann, Feb 18 Rebuttal, Page 2

9. **Study Areas for CEA -** The Bipole III Project CEA uses a very broad regional study area, and a Local Study Area that is 4.8 km wide centred on the route for the HVdc transmission

---

[6] In this regard, the Guide does not support Dr. Noble's evidence as follows on this point (November 15, Page 4851): "The point is that unless you have some established threshold, you can't really identify or comment on the significance of the cumulative effect." If further guidance is sought on this matter, Section 3.5.3 of the Guide addresses what the practitioner can do in the absence of defined thresholds (including "acknowledge that there is no threshold, determine the residual effect and its significance, and let the reviewing authority decide if a threshold has been exceeded").

[7] In the hearing, Dr. Noble responded to a question from Mr. Beddome on this matter, saying (November 15, Page 5002) that the "operational policy statement for cumulative effects assessment at the federal level specifically requires catastrophic events to be considered, like major spills or risks, in good practice cumulative effects" and that "it's an important part of the consideration of cumulative effects." Mr. Hegmann's rebuttal confirms that there is no known support for Dr. Noble's testimony on this matter.

line and the area immediately surrounding other Project components; broader study areas beyond the Local Study Area are considered in the Bipole III EIS for the assessment of VECs as required and appropriate, and vary considerably based on the nature of the cause-effects on VECs. For linear projects such as transmission lines, use of a study area based on a linear corridor is common practice, and is commonly represented by a buffer along each side of the project right-of-way. As such, the use of the Local Study Area in the Bipole III CEA does not necessarily represent a deficiency. In this regard, the Bipole III CEA represents current practice and the Guide supports this view[8].

Evidence of G. Hegmann, Feb 18 Rebuttal, Page 2
Exhibit MH-59, Slides 20-21

10. **Regulatory Significance –** Following from experience working with First Nation partners on the Keeyask Generation Project EIS, the Bipole III EA and CEA uses the term "regulatory significance" to differentiate the technical and objective standard of significance required to be met by the CEAAct from other non-technical or non-regulatory interpretations, i.e., the CEAA guides on significance provide that significance determination is an objective exercise and not a question of personal point of view or public opinion. In relation to First Nation concerns in northern Manitoba, it is understood that the regulatory perspective of evaluating environmental effects of the Project that focuses on assessing the effects on certain VECs does not often fit with a holistic or Aski world view. – however, this difference in views has not stopped Manitoba Hydro from filing EISs (e.g., Keeyask Generation Project EIS) for new projects with First Nation partners and having these EISs include basically similar VEC selection, assessment and significance determinations as are provided in the Bipole III Project EIS. The material issues and concerns raised by affected northern Aboriginal communities such as TCN and FLCN are not readily or very appropriately addressed through VEC analysis in effects assessment – this includes issues of lack of trust, lack of involvement and a desire to be heard regarding past experiences with northern development and what has

[8] The definition of the Local Study Area in the Bipole III EIS did not prevent, where relevant, the assessment of Project effects on a given VEC from extending beyond the Local Study Area into the much broader Project Study Area, e.g., Chapter 9 and response to CEC/MH-VI-347 identify the relevant VECs in this regard (climate, boreal woodland caribou and several socio-economic VECs). Broader regional analysis was also done more recently for moose (and the technical analysis for various VECs also included consideration of context information beyond the Local Study Area). Defining study areas is a matter separate from the type of CEA analysis carried out for a VEC in the defined area on a VEC, and the evidence of Drs. Gunn and Noble on this issue often focuses on a preferred method of analysis such as use of landscape indicators.

been learned. These issues are being addressed by Manitoba Hydro on an ongoing basis through continued dialogue focused on developing an effective relationship with these communities.

Evidence of C. Osler pages 3099-3101 and pages 5824 to 5826.

11. **Scoping Future Projects into CEA -** Prospective future projects and human activities were defined in the Bipole III CEA as "not yet approved nor in a planning/approvals process preparatory to being constructed/carried out" and are listed in Table 9.2-3. This table includes prospective future transmission projects in southern Manitoba that have recently received a lot of discussion at this CEC hearing, namely the New International Transmission Line and prospect of further development of new transmission lines in southern Manitoba (e.g., Letellier/St. Vital line; St. Vital- LaVerendrye). Each of these projects were in early planning stages at the time the Bipole III EIS was filed and without adequate definition or other information to support any meaningful inclusion in the Bipole III CEA assessment. It was noted in Chapter 9 of the EIS for each of these transmission lines that the project would not occur without comprehensive route selection and environmental impact assessment (which has still yet to occur as at March 2013), extensive public consultation and approval and licensing by the relevant regulatory authorities.

Chapter 9, Table 9.2-3: Prospective Future Projects & Activities
CEC-MH-III-090; CEC-MH-III-091;
Evidence of C Osler, Pages 3216 to 3229

12. **Methods used to support regulatory CEA** - Although techniques such as the use of landscape or stream crossing indicators and computer based models are not required by the Guide to support a regulatory CEA, in the Bipole III EIS similar techniques were applied where appropriate. For example, technical studies were provided on Habitat Fragmentation, and the recent Supplemental Enhanced Assessment for Moose filed in February 2013 included analysis of linear disturbance on a landscape scale and the use of computer based models, confirming (page 47) that landscape and linear development do not explain moose decline in western Manitoba[9].

Habitat Fragmentation Technical Report (November 2011)
Enhanced Assessment for Moose (February 2013)
Evidence of G. Hegmann, Feb 18 Rebuttal, Page 3

[9] The critique by Drs. Gunn and Noble includes recommended studies that Manitoba Hydro does not see to be reasonable in the case of the Bipole III Project CEA, including (by way of example) the recommendation of a full CEA to all water crossings (pages 38 and 45) and wetlands (page 38 and 53-54). In the case of water crossings, the Project complies with strict and highly successful federal requirements such that no federal EIA is required regarding aquatic (fish and fish habitat) impacts due to the commitment to follow Department of Fisheries and Oceans operational statements as summarized in the December 2011 EIS (pages 8-48 to 8-51) and also reflecting the plan to focus construction in such areas during the winter season timing windows (which further minimizes any potential effects). In the case of wetlands, this is not a VEC for this project - for the reason that no material evidence has surfaced to suggest that this Project is likely to have any notable effect on wetlands.

1. Introduction

Manitoba Hydro provided detailed information to the Manitoba Public Utilities Board (PUB) on its Preferred Development Plan and alternatives beginning with its Business Case, delivered in August 2013. Subsequent information was provided through IRs and supplementary information disclosures (some of which were commercially sensitive) to participants in the PUB's process.

Morrison Park Advisors reviewed and analyzed the information provided, and commented on it in its Report (January 2014), in various responses to IRs from the PUB and other participants, and in its presentation and verbal comments before the PUB (April 2014).

Coincident with the commencement of public hearings before the PUB, Manitoba Hydro began releasing updates to the Preferred Development Plan (PDP) and to various potential alternatives. These updates take into account both changes in the external environment (e.g., inflation rates and natural gas price projections), and changes in Manitoba Hydro management expectations (e.g., cost of construction for various proposed projects).

Given changes to multiple variables simultaneously, it is impossible to accurately predict the combined outcome on the relative attractiveness of the various alternatives presented by Manitoba Hydro absent testing of the new data. As a result, MPA updated its own models based on the new data provided by Manitoba Hydro, analyzed the outputs in detail, and presents its results in this supplementary report.

1.1. New Information Provided by Manitoba Hydro

Manitoba Hydro provided new information for the following Plans:

Table 1. Comparison of Updated to Original Plans

Plan	Elements (2013 version) (base DSM)	Elements (2014 version) (DSM level 2, no pipeline)
1	*All Gas* • Single cycle natural gas units added in 2022-23, 2025-26, 2028-29, 2034-35, 2047-48 • Combined Cycle natural gas units added in 2031-32, 2037-38, 2040-41, 2044-45	*All Gas* • Single cycle natural gas units added in 2031-32, 2035-36, 2039-40, 2047-48 • Combined Cycle natural gas unit added in 2042-43
2	*K22/Gas* • Keeyask Hydroelectric Generating Station in 2022-23 • Single cycle natural gas units added in 2029-30, 2032-33 • Combined Cycle natural gas units added in 2034-35, 2038-39, 2041-42, 2045-46	*K31/Gas* • Keeyask Hydroelectric Generating Station in 2031-32 • Single cycle natural gas units added in 2040-41, 2044-45, 2047-48

Plan	Elements (2013 version) (base DSM)	Elements (2014 version) (DSM level 2, no pipeline)
4	*K19/Gas24/250MW* • Keeyask Hydroelectric Generating Station in 2019-20 • 250 MW Transmission Interconnect in 2020-21 • Single cycle natural gas units added in 2024-25, 2029-30 • Combined Cycle natural gas units added in 2032-33, 2038-39, 2041-42, 2045-46	*K19/Gas40/250MW* • Keeyask Hydroelectric Generating Station in 2019-20 • 250 MW Transmission Interconnect in 2020-21 • Single cycle natural gas units added in 2040-41, 2044-45, 2047-48
5	*K19/Gas25/750MW(WPS Inv.)* • Keeyask Hydroelectric Generating Station in 2019-20 • 750 MW Transmission Interconnect in 2020-21 • Interconnect will be partially owned and funded by a US investor • Single cycle natural gas units added in 2025-26, 2026-27, 2028-29, 2031-32, 2033-34, 2045-46, 2047-48 • Combined Cycle natural gas units added in 2042-43	*K19/Gas31/750MW* • Keeyask Hydroelectric Generating Station in 2019-20 • 750 MW Transmission Interconnect in 2020-21 • Single cycle natural gas units added in 2031-32, 2044-45, 2047-48
6	*K19/Gas31/750MW* • Keeyask Hydroelectric Generating Station in 2019-20 • 750 MW Transmission Interconnect in 2020-21 • Single cycle natural gas units added in 2031-32 (x2), 2032-33, 2034-35, 2043-44 • Combined Cycle natural gas units added in 2039-40, 2045-46	*K19/Gas40/750MW* • Keeyask Hydroelectric Generating Station in 2019-20 • 750 MW Transmission Interconnect in 2020-21 • Single cycle natural gas units added in 2040-41, 2044-45, 2047-48
14	*K19/C25/750MW(WPS Inv.)* • Keeyask Hydroelectric Generating Station in 2019-20 • 750 MW Transmission Interconnect in 2020-21 • Interconnect will be partially owned and funded by a US investor • Conawapa Hydroelectric Generating Station in 2025-26 • Single cycle natural gas units added in 2041-42, 2044-45, 2046-47	*K19/C31/750MW* • Keeyask Hydroelectric Generating Station in 2019-20 • 750 MW Transmission Interconnect in 2020-21 • Conawapa Hydroelectric Generating Station in 2031-32

The original versions of the Plans, provided in August 2013, assumed the 2012 Manitoba load forecast, and a "base" level of Demand Side Management (DSM), as per the programs approved by the PUB at the time. The 2014 versions of the Plans assume the newer 2013 Manitoba load forecast and substantially higher "Level 2" spending on DSM. The difference is significant, and causes dramatic changes in the timing and composition of energy generation investments by Manitoba Hydro.

Investment in DSM (e.g., subsidies for efficiency measures such as improved lighting and motors, fuel switching for heating purposes from electricity to natural gas, subsidies for combined heat and power or waste heat electricity generation at industrial facilities, etc.) means that net load measured on the

Manitoba grid will be significantly reduced over time, as compared to current projections. This should have two impacts: more of Manitoba's Hydro's electricity production from existing facilities should be available for export (particularly in "wet" years), and new facilities to provide dependable energy will not be needed until later in the period under study. As a result, the revised plans include fewer single cycle and almost no combined cycle natural gas-fired generation units over the course of the next forty years.

Annual expenditures on DSM will be much higher throughout the period studied, but assuming the net cost of DSM investments is lower than the cost of the new generation being avoided, then Manitoba consumers as a whole should be better off.

[Note: this is an assumption made about Manitoba electricity consumers *collectively*. DSM programs by definition apply unequally across consumers when considered individually. DSM programs typically result in a higher price per unit energy because total demand is reduced, while system fixed costs – including DSM spending – do not fall with demand. Consumers who respond to DSM programs and reduce their consumption will benefit from the DSM investments, while consumers who do not participate in DSM programs and therefore do not reduce their power consumption will potentially pay more for their electricity. The rest of this paper focuses exclusively on collective customer rate impacts, and will not comment on the potential distributional effects of DSM within the Plans.]

As noted in Table 1, the additional load that may result from new interprovincial pipelines that might be built in the future was not included in the scenarios tested by MPA. According to Manitoba Hydro, such pipelines could increase Manitoba load by 1300 GWh by 2027 if they are built. This would reduce Manitoba Hydro's ability to export power, and may require changes in the timing of new generation units in certain plans.

Capital costs for the Keeyask and Conawapa projects have been increased, in accordance with the most recent construction contracts entered into by Manitoba Hydro.

The WPS Investment in the transmission interconnection with the United States that was assumed in certain Plans in 2013 is no longer assumed in any Plans. Manitoba Hydro is instead assumed to absorb the portion of the capital cost that was previously assigned to WPS, and recover those expenditures over time through other arrangements.

Common costs shared by all Plans (such as transmission, distribution and administrative costs) have been updated to match the recently released 2013 IFF and 2013 CEF.

Interest and inflation forecasts have also been updated. The following table highlights changes in the economic variables used in the analysis of the Plans:

1 **Table 2. Comparison of Updated Economic Variables**

Indicator		**2013**	**2014**	**2015**	**2016**	**2017**	**2018**	**2019**	**2020+**
Manitoba CPI Inflation (%)	2013	1.70	1.80	1.80	1.80	1.80	1.80	1.90	1.90
	2014	1.70	1.80	2.00	2.00	2.00	2.00	2.00	2.00
	Difference	0	0	+ 0.20	+ 0.20	+ 0.20	+ 0.20	+ 0.10	+ 0.10
Manitoba Hydro Long Term $CDN Debt Rate (%)	2013	4.15	4.30	4.85	5.55	5.95	6.15	6.30	6.30
	2014	4.15	4.50	4.85	5.20	5.95	6.40	6.75	6.75
	Difference	0	+ 0.20	0	- 0.35	0	+ 0.25	+ 0.45	+ 0.45
Manitoba Hydro Equity Rate (%)	2013	7.15	7.30	7.85	8.55	8.95	9.15	9.30	9.30
	2014	7.15	7.50	7.85	8.20	8.95	9.40	9.75	9.75
	Difference	0	+ 0.20	0	- 0.35	0	+ 0.25	+ 0.45	+ 0.45
Nominal Weighted Average Cost of Capital	2013								7.05
	2014								7.50
	Difference								+ 0.45

2

Taken together, all of these changes result in dramatically different Plans for consideration. Timing and extent of investments has changed, relative importance of exports vs. domestic load has changed (because of lower Manitoba demand), and capital costs have changed for both internal and external reasons. The only commonality between the “new” and “old” versions of the Plans are potential investments in Keeyask, Conawapa and transmission interties.

1.2. Scenarios

In August 2013 Manitoba Hydro provided data for and analysis of the various Plans in light of 27 different scenarios, based on High, Reference and Low forecasts for groups of variables relating to energy prices, capital costs and the economy. In addition, other cases were developed and examined relating to higher and lower demand expectations, and the possibility of droughts at different times in the future.

Comprehensive data for the 2014 updated Plans has been provided for a single scenario: reference economics, reference energy and reference capital costs (Ref/Ref/Ref).

Based on our model, MPA can and did test the impact of alternative interest costs (as a proxy for broader economic variables) and increased costs for construction of Keeyask and Conawapa (as a proxy for capital cost variables). This should be understood as sensitivity testing, rather than scenario analysis, however.

MPA could *not* test sensitivity to alternative energy prices. Changes in the price of electricity exports and natural gas purchases have important impacts on Manitoba Hydro’s expected behaviour at a plant level: depending on relative prices of exports, natural gas and domestic electricity rates, decisions are made whether to use or build up water reserves, and decisions are made between buying imported power and running domestic plants. These are the critical outputs of Manitoba Hydro’s SPLASH model. Data from Manitoba Hydro’s SPLASH model has been provided only for Reference energy prices, not for High or Low energy prices. MPA’s analysis of potential alternative energy price scenarios must perforce be restricted to conjectures based on the impact of energy prices on the 2013 Plans provided by Manitoba Hydro.

Also, while load forecasts are updated with respect to the 2014 versions of the Plans, Manitoba Hydro did not provide additional data from SPLASH model runs with higher or lower Manitoba demand. Again, MPA’s analysis must be restricted to comparisons with previously provided information.

1.3. New Analysis and Previous Conclusions

As summarized in MPA’s presentation to the PUB in April 2014, we ultimately came to the following conclusions based on all of the information provided to us based on Manitoba Hydro’s 2013 Plans:

a) In our view, there was no compelling commercial reason to not go ahead with the Keeyask and transmission interconnection projects, as described in the Preferred Development Plan and several other alternative plans;

b) Conawapa – which in our view is better understood as an ongoing development project rather than an immediate commercial opportunity as is Keeyask – faces a higher burden which does not appear to be met: it is not clearly commercially superior to alternatives, in fact appears to be less attractive than certain other alternatives, and therefore Manitoba Hydro should be required to demonstrate why it is appropriate to continue spending development capital on the project instead of pursuing alternatives.

In considering the new information provided by Manitoba Hydro, we were guided by these conclusions with respect to our further analysis:

- Does the new information suggest that alternatives are now clearly commercially superior to proceeding with Keeyask and the transmission interconnection?
- Is Conawapa now more attractive than alternatives as a development opportunity?

1.4. Note on Adjustments to the Model

MPA's financial model is identical to the version used to test the original data provided by Manitoba Hydro. No changes were made in order to ensure that new versions of the Plans can be compared to original versions.

A critical feature of the model is the domestic rate-setting mechanism. Manitoba domestic rates are set based on Manitoba Hydro's expected financial performance, as well as based on export prices and volumes. Crucially, changes from year to year are constrained to a maximum of two times the rate of inflation.

In the original data provided by Manitoba Hydro, long-term inflation in the Reference economics scenario was 1.9% per year. This resulted in a maximum change in Manitoba domestic rates of 3.8% per year (either up or down).

In the 2014 data recently provided, long-term inflation is assumed to be 2% per year, which would result in a maximum annual rate change in our model of 4% per year. The difference of 0.2% per year in maximum change in rates may not at first appear significant, but over the course of 20 years, that small difference in rates does become significant. For example, assuming an initial rate of 100, after 20 years of 3.8% increases the ending rate would be 210. If the rate of increase is instead 4%, then the ending rate is 219. Considered over large volumes of energy, such rate changes could have important impacts on Manitoba Hydro finances.

In order to provide insight to the potential impact of rate-setting decisions, MPA tested the model set to both a maximum change in annual rates of 3.8% and 4%.

2. Model Outputs

For each of the Plans (All Gas, 2, 4, 5, 6, PDP), MPA modeled the financial performance of Manitoba Hydro for each of the 99 hydrology patterns provided (the same patterns that were reviewed in our January report to the PUB). A variety of outputs were collected, including ratepayer costs, government revenues, export revenues, etc. In each case, raw outputs were summarized by averaging the results of the 99 hydrology patterns, recording high and low results, and the standard deviations around the mean (note that in an assumed "normal" distribution such as hydrology, approximately two thirds of cases should be within one standard deviation of the mean).

In addition, net present values for the results were calculated at both 6% and 10%.

2.1. Ratepayer Total Costs

Figure 1 below presents the total costs to Manitoba ratepayers over the life of the model, for the Ref/Ref/Ref Scenario. This calculation has been performed based on a 3.8% per year maximum change in domestic rates, consistent with MPA's January report.

Figure 1. Total Cost to Ratepayers at a 3.8% Maximum Annual Rate Change

Present Value and Nominal Value of Domestic Revenue
Reference Economics, Energy and Capital
Reference 2013 Manitoba Load; DSM Level II
(2015 - 2062)
($ in millions)

	All Gas	Plan 2	Plan 4	Plan 5	Plan 6	PDP
Present Value						
NPV @ 6.00%						
Average	$39,659	$40,284	$39,440	$39,636	$39,696	$41,999
Maximum	$40,915	$41,569	$40,561	$40,671	$40,816	$43,854
Minimum	$38,596	$39,282	$38,274	$38,571	$38,642	$40,815
Standard Deviation	$486	$485	$494	$465	$492	$708
Present Value						
NPV @ 10.00%						
Average	$21,999	$22,248	$22,225	$22,312	$22,345	$23,322
Maximum	$22,406	$22,720	$22,561	$22,666	$22,736	$23,886
Minimum	$21,583	$21,787	$21,737	$21,864	$21,895	$22,961
Standard Deviation	$201	$257	$183	$168	$172	$225
Nominal Value						
Average	$161,316	$162,570	$151,161	$151,791	$151,794	$158,555
Maximum	$172,403	$176,999	$161,403	$164,331	$162,887	$172,101
Minimum	$153,275	$154,896	$141,117	$142,701	$142,824	$149,689
Standard Deviation	$4,568	$4,059	$4,278	$4,212	$4,449	$4,950

Some notable comparisons can be observed:

- The results for Plans 4, 5 and 6 (all of which include Keeyask but not Conawapa) are within 1% of each other across all cases (NPV at 6% or 10%, as well as nominal dollars, and also across maximum, minimum and average values).

- Plan 4, which includes Keeyask and a 250 MW intertie, is very slightly superior in all cases to Plan 5, which includes Keeyask and a larger intertie. However, the difference between the two Plans is approximately half of one percent, which is well within the margin of error that should be assumed for a model of this sort.
- Plan 2, which includes Keeyask but no transmission intertie, and is therefore a domestically focused Plan, is slightly inferior to Plans 4, 5, and 6 at an NPV of both 6% and 10%. However, in nominal dollar terms it is significantly inferior, which indicates that its costs to ratepayers are higher further out in the future.
- The All Gas Plan is competitive with Plans 4, 5, and 6 at an NPV of 6%, but slightly superior (by approximately 1%) at an NPV of 10%. However, in nominal dollar terms the All Gas Plan has the highest ratepayer cost of all Plans modeled, which indicates that its costs to ratepayers are significantly higher further out in the future.
- The PDP is approximately 5% inferior to Plans 4, 5 and 6 across all cases. It is the worst performing Plan in terms of NPV calculated at both 6% and 10%, but is superior to the All Gas Plan and Plan 2 in nominal dollar terms. The PDP also has the highest standard deviation, which suggests that it is the most sensitive to hydrology. Notably, there is no discount rate at which the PDP is superior to Plans 4, 5 and 6: they are superior to the PDP regardless of discount rate assumptions (note that nominal dollars are equivalent to a discount rate of 0%).

Figure 2 presents the same information as Figure 1, based on the application of a maximum 4% annual change in rates in the model.

Figure 2. Total Cost to Ratepayers at a 4% Maximum Annual Rate Change

Reference Economics, Energy and Capital
Reference 2013 Manitoba Load; DSM Level II
(2015 - 2062)
($ in millions)

	All Gas	Plan 2	Plan 4	Plan 5	Plan 6	PDP
Present Value						
NPV @ 6.00%						
Average	$39,687	$40,313	$39,454	$39,633	$39,699	$42,040
Maximum	$40,830	$41,497	$40,557	$40,581	$40,692	$43,533
Minimum	$38,652	$39,356	$38,273	$38,520	$38,651	$40,858
Standard Deviation	$493	$491	$498	$460	$479	$432
Present Value						
NPV @ 10.00%						
Average	$22,071	$22,285	$22,302	$22,400	$22,439	$23,507
Maximum	$22,409	$22,816	$22,695	$22,714	$22,759	$23,987
Minimum	$21,588	$21,860	$21,834	$21,958	$21,989	$23,115
Standard Deviation	$204	$256	$202	$170	$173	$141
Nominal Value						
Average	$160,890	$162,840	$150,881	$150,990	$150,948	$155,786
Maximum	$174,221	$176,603	$161,941	$164,688	$162,469	$165,868
Minimum	$151,390	$156,667	$141,592	$141,259	$139,321	$148,197
Standard Deviation	$4,851	$4,080	$4,333	$4,423	$4,674	$3,113

Some observations:

- As compared to the results with a 3.8% maximum change in rates, the NPVs at both 6% and 10% are slightly higher across all Plans when a 4% maximum change in rates rule is applied. However, total cost to Manitoba ratepayers in nominal dollar terms is lower. This impact is a result of higher rate increases in early years, and lower rates in later years, across all Plans.
- Rank ordering between the Plans has not changed despite the move from 3.8% maximum changes in rates to 4% maximum changes in rates. However, the gap between Plans has changed: the difference between the PDP and Plans 4, 5 and 6 has narrowed somewhat, as has the gap between Plan 2 and Plans 4, 5 and 6 when discounted.
- The standard deviation applicable to the PDP has significantly decreased. This suggests that more rapid increases in domestic rates and revenues, and the concomitant reduction in debt and interest charges that would result for Manitoba Hydro, are critical to reducing the sensitivity of the PDP to the hydrological performance of Manitoba's generation fleet.

2.2. Comparison to 2013 Plans

As noted in section 1.1. above, the updated versions of the Plans contain a number of significant changes from the versions provided in 2013. This has resulted in significant changes in the projected costs to Manitoba ratepayers. The Figure below summarizes the differences in NPV at 6% and 10%, based solely on the Ref/Ref/Ref scenario, with a maximum rate change of 3.8% per year.

Figure 3. Comparison of 2013 and 2014 Ratepayer Costs

Present Value of Domestic Revenue
Reference Economics, Energy and Capital
2013 Plans vs. 2014 Plans
(2015 - 2062)
($ in millions)

	All Gas	Plan 2	Plan 4	Plan 5	Plan 6	PDP
Present Value						
NPV @ 6.00%						
2013 Average	$43,791		$42,878		$43,301	$44,230
2014 Average	$39,659	$40,284	$39,440	$39,636	$39,696	$41,999
Difference	-$4,132		-$3,438		-$3,605	-$2,231
%	-9.4%		-8.0%		-8.3%	-5.0%
NPV @ 10.00%	$23,623		$23,476		$23,633	$24,148
2013 Average	$21,999	$22,248	$22,225	$22,312	$22,345	$23,322
2014 Average	-$1,624		-$1,251		-$1,288	-$826
Difference	-6.9%		-5.3%		-5.4%	-3.4%
%						

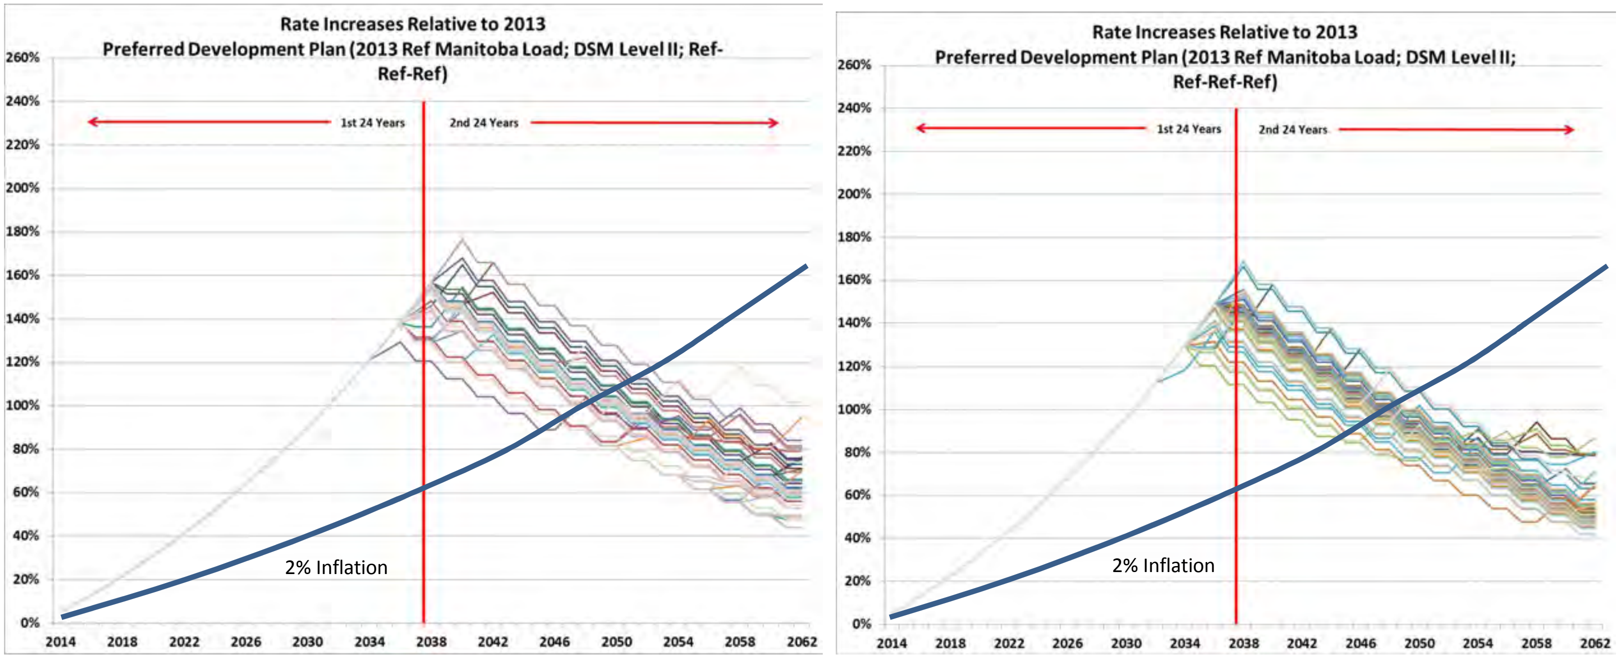
Across all Plans, projected total costs for Manitoba ratepayers have declined.

- It is notable that this decline has occurred *despite* the fact that expected interest rates have increased, capital costs for projects have increased, and inflation rates have increased slightly.
- The declines speak to the powerful impact of dramatically expanded DSM programs (4x the spending contemplated in the 2013 Business Case), which are expected to dramatically reduce Manitoba domestic load, and free up more capacity for export. Moreover, as noted above, the Plans themselves now contemplate a much reduced level of capital spending on generation projects (and generally later in time), though of course spending on enhanced DSM programs will begin almost immediately.
- The gap between All Gas and the Keeyask-based Plans has narrowed. All Gas is now marginally superior to Plans 4, 5 and 6 at a 10% discount rate, and essentially identical at a 6% discount rate. Based on the 2013 Plans, Plans 4 and 6 were superior to All Gas at 6%, and Plan 4 was also superior at 10%.
- The gap between the PDP and the other Plans has actually increased as compared to the 2013 versions of the Plans.

2.3. Rate Paths

Some of the observations made above with respect to ratepayer costs can be more easily illustrated by reference to projected rate increases in the future. For example, Figure 4 (below) presents rate increases for the PDP under 3.8% and 4% maximum annual rate changes.

Figure 4. Cumulative Rate Increases for the PDP under 3.8% and 4% Annual Rate Change Rules

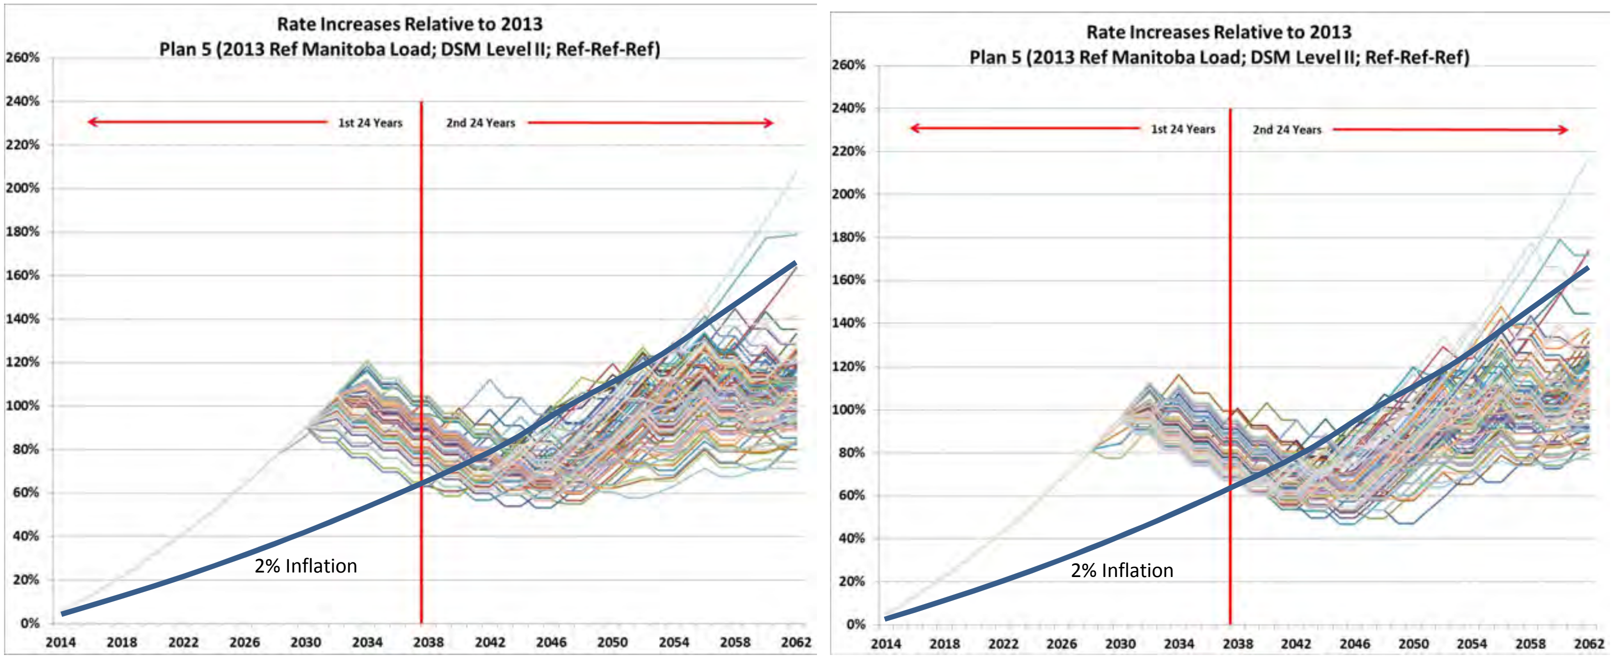


The graph on the left depicts the rate paths for the 99 hydrological patterns for the PDP under the Ref/Ref/Ref scenario, with the application of a 3.8% rule for maximum annual change in Manitoba domestic rates. On the right, the results are depicted for exactly the same assumptions, except for the use of a 4% maximum annual rate change rule. Since in both cases maximum annual rate increases are required for the first 20 years of the model, it can be seen that customer rates in Manitoba are approximately 9% higher in the year 2034 in the right hand graph. By the year 2038, the mid-point of the model period, rates in the right hand graph have peaked for virtually all of the 99 hydrological patterns tested, and rate declines have already begun in many instances. The left hand graph depicts that rates have not yet peaked in 2038 for many hydrological patterns, and the definitive turn downwards does not begin until 2040 or slightly later.

An observation that can be drawn from this comparison is that higher rates in the early years of the PDP would bring rates in later years down even further. However, such a change would simply accentuate the trade-off being made between the welfare of ratepayers in different periods of time.

Figure 5 (below) depicts the rate paths that would result from Plan 5 under the same conditions.

Figure 5. Cumulative Rate Increases for Plan 5 under 3.8% and 4% Annual Rate Change Rules

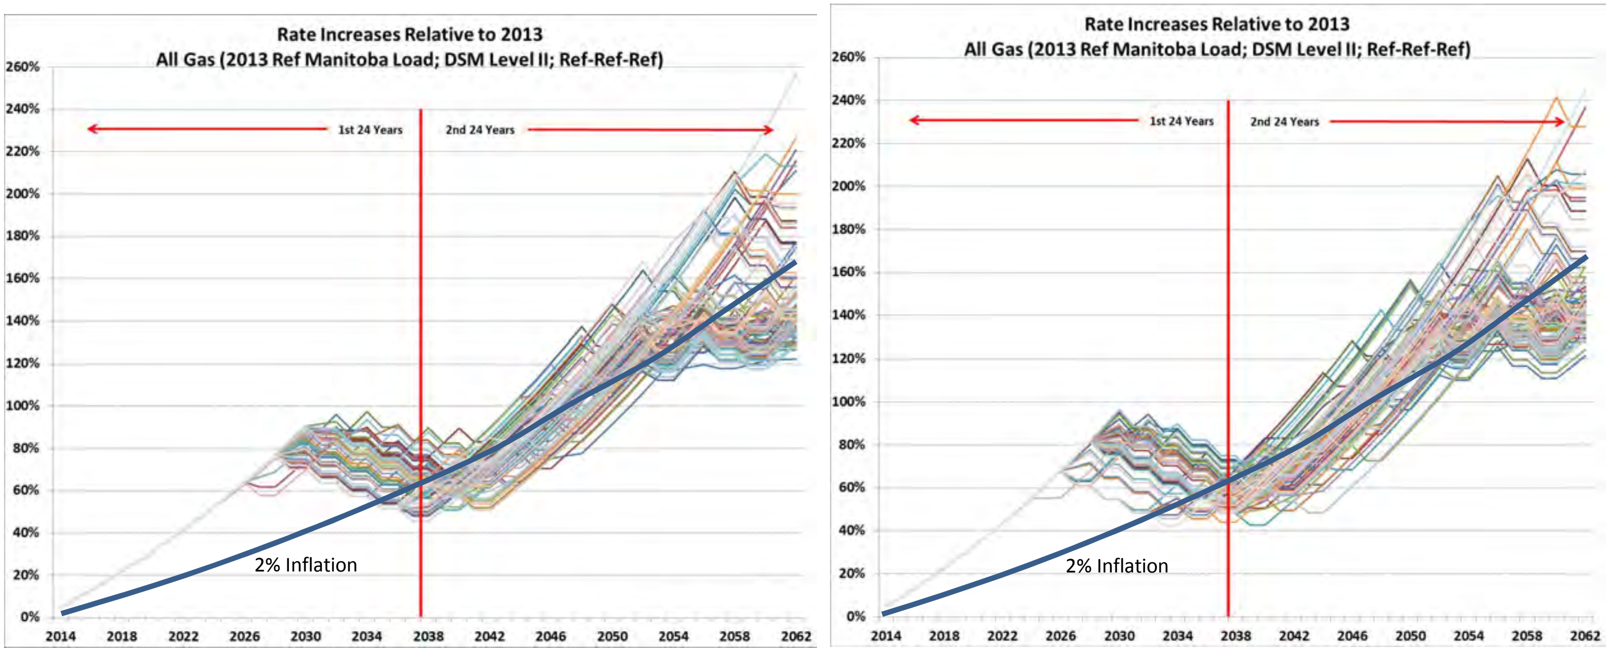


Cumulative rate increases for Plan 5 appear to peak in the early 2030s, before the mid-way point of the model is reached, then fall for approximately 10 years, and then rise again at a rate less than the maximum allowable (for all but a few hydrological patterns). With the higher allowable 4% change in rates, the peak appears to occur slightly earlier, as would be expected, and the distribution of the rate paths appears to be somewhat more compact until the late years of the model, suggesting that the higher domestic revenues resulting from higher Manitoba rates would reduce the sensitivity of Manitoba Hydro to financial stresses from hydrological patterns.

As compared to the PDP, the rate path is radically different, and represents a significantly different inter-generational choice with respect to the allocation of costs and benefits over time.

Figure 6 (below) provides the expected rate paths for the All Gas Plan.

Figure 6. Cumulative Rate Increases for All Gas under 3.8% and 4% Annual Rate Change Rules



The All Gas Plan represents yet another intergenerational allocation of costs and benefits, with cumulative Manitoba rate increases peaking in the late 2020s, then declining modestly for a decade, before strongly increasing again. This pattern is consistent with the results noted in Section 2.1, above, where the All Gas Plan was superior to the PDP at a NPV of 6%, and especially at 10% (because it entails lower rates in the earlier years of the model), but was significantly inferior to the PDP in nominal dollar terms (because of the impact of the very high prices under All Gas in the later years of the model). As compared to Plan 5, cumulative rate increases for All Gas are identical until the late 2020s, then All Gas rates are somewhat lower for approximately 10 years, before Plan 5 rates permanently fall below All Gas rates in the late 2030s.

The impact of the higher annual rate change limit, as with the other Plans, is to marginally shorten the initial period of maximum rate increases, and then to make the decline in customer rates more decisive, before allowing them to rise again.

2.4. Sensitivities

As noted above, Manitoba Hydro has not provided data for the updated Plans across the full range of 27 scenarios that were defined in August 2013. Absent SPLASH outputs for energy pricing alternatives, sensitivities of updated Plans to energy price changes cannot be calculated. This will be discussed further below. However, MPA's model provides the flexibility to test the sensitivity of the Plans to changes in nominal interest rates and to higher construction costs.

All sensitivities were calculated based on the 3.8% maximum annual change in domestic rates rule, in order to allow comparison to modeling work previously undertaken by MPA.

2.4.1. Interest Rates

As noted in section 1.1. above, Manitoba Hydro assumed long-term interest rates of 4.50% for 2014, rising to 6.75% for 2019 onwards. Changing these interest rate assumptions will raise or lower the projected debt interest costs to Manitoba Hydro, and will have a strong impact on the company's finances.

Typically, interest rate changes do not occur in isolation, since changes in interest rates are usually at least partly correlated with changes in inflation rates (as changes in interest costs permeate the economy they have an impact on prices for all goods, to a greater or lesser extent depending on a variety of elasticities of demand and price). However, in our model interest rate changes are isolated from inflation, so a 1% increase in interest charges does not affect assumed inflation (this is equivalent to a 1% change in "real" interest rates). Such a change could occur in the real world if, for example, the cost of debt to the Province of Manitoba (and hence Manitoba Hydro) were to rise or fall because the capital markets change their view of the Province's economic or fiscal performance. In such a case, underlying Canada interest rates would not change, and inflation would likely not be affected to any significant degree. As was noted in our January report, historically the "spread" between Manitoba and Canada has actually fluctuated substantially over time, without relationship to inflation, so this scenario is not far-fetched.

For the purposes of the current analysis, testing the sensitivity of the Plans to changes in interest rates is a proxy for the High/Reference/Low economic scenarios that were previously tested.

Figure 7 (below) summarizes the expected total cost to ratepayers from both an increase and a decrease in interest rates of 1%.

Currently, Manitoba's electricity system has the following output characteristics:

Minimum	$146,923	$149,118	$136,304	$137,046	$136,294	$134,001
Standard Deviation	$4,248	$3,271	$3,604	$3,658	$3,786	$3,351

Interest rates have some clear impacts on total costs to Manitoba ratepayers:

- Changes in interest rates have the greatest impact on the PDP, which employs the greatest amount of debt capital, and the least impact on the All Gas Plan, which employs the least amount of debt capital.

- For Plan 5, a 1% increase in interest rates causes the NPV (at 6%) of Manitoba ratepayer costs to rise by approximately 6.5%. For All Gas this sensitivity is only 4.5%, while for the PDP the sensitivity is 9.5%.
- At lower interest rates the PDP becomes relatively more attractive, since the gap between the NPV (at a 6% rate) of the PDP and Plans 4, 5 and 6 has narrowed to approximately 4%. In nominal dollar terms the PDP actually has the lowest total cost to Manitoba ratepayers over the life of the model (which suggests that at a very low discount rate the NPV of the PDP would overtake the other Plans).
- Interestingly, at lower interest rates the difference between All Gas and Plan 2 (which includes Keeyask but no transmission intertie) essentially disappears.
- At higher interest rates the All Gas Plan is superior to all alternatives at both the 6% and 10% NPVs, but not in nominal dollar terms (which suggests that Plans 4, 5 and 6 would be superior to All Gas at a very low discount rate). However, it should be noted that the difference between the NPVs (at a 6% rate) of the All Gas and Plans 4, 5 and 6 are separated by slightly more than 1%, which is a barely significant difference.
- At higher interest rates the PDP is the most expensive Plan under all discount rates (including nominal dollars, which is a 0% discount rate).

2.4.2. Construction Costs

Figure 8 (below) presents the results of modeling for total ratepayer costs in the event that the construction costs of Keeyask and Conawapa are higher than currently forecast by $1 Billion (in 2014 $).

Note that this sensitivity is not a calculation of generally higher capital costs, but a calculation of the sensitivity of the Plans to specific project cost overruns. If construction costs are generally higher, then all Manitoba Hydro capital investments become more expensive, including those relating to transmission, distribution and administration. MPA does not have the means to calculate such a sensitivity since it does not have access to detailed Manitoba Hydro common cost information.

Figure 8. Sensitivity to Construction Cost Increases

Present Value and Nominal Value of Domestic Revenue
Reference Economics, Energy and Capital
Reference 2013 Manitoba Load; DSM Level II
(2015 - 2062)
($ in millions)

Sensitivity: + $1 Billion for Keeyask, + $1 Billion for Conawapa (2014 $)

	All Gas	Plan 2	Plan 4	Plan 5	Plan 6	PDP
Present Value						
NPV @ 6.00%						
Average	$39,659	$40,937	$40,496	$40,729	$40,768	$43,975
Maximum	$40,915	$42,140	$41,738	$41,787	$41,927	$45,252
Minimum	$38,596	$39,903	$39,415	$39,751	$39,813	$42,549
Standard Deviation	$486	$504	$503	$462	$486	$526
Present Value						
NPV @ 10.00%						
Average	$21,999	$22,483	$22,641	$22,742	$22,756	$23,915
Maximum	$22,406	$22,900	$22,992	$23,037	$23,081	$24,276
Minimum	$21,583	$21,997	$22,252	$22,419	$22,439	$23,482
Standard Deviation	$201	$265	$168	$147	$145	$147
Nominal Value						
Average	$161,316	$166,224	$156,295	$156,941	$157,233	$173,282
Maximum	$172,403	$183,673	$168,821	$169,759	$168,430	$183,628
Minimum	$153,275	$158,664	$144,142	$147,314	$147,132	$163,259
Standard Deviation	$4,568	$5,068	$4,374	$4,366	$4,552	$4,358

The impact of higher construction costs is very similar to the impact of higher interest rates:

- This sensitivity has no impact on the All Gas Plan, since cost increases were tested only for the Keeyask and Conawapa projects.
- Adding $1 billion to the construction cost of Keeyask causes Plan 5 NPV (at 6%) of ratepayer costs to rise by slightly less than 3%. At this level, All Gas is approximately 2% superior to Plan 5 (or the other Plans including Keeyask in 2019). However, at lower discount rates Plans 4, 5 and 6 would still be superior to All Gas.
- The PDP is clearly inferior to all other Plans if both Keeyask and Conawapa construction costs are increased.

2.4.3. Energy Prices

As noted above, Manitoba Hydro did not provide SPLASH data for High and Low energy prices applied to the updated Plans, as they did for the 2013 Plans. As a result, it is not possible for MPA to examine in detail the potential impact on Manitoba ratepayers if energy prices were to fluctuate away from Reference assumptions. However, based on the work completed previously, and the new information available, it is possible to make “educated guesses” as to the sensitivity of the various Plans to energy prices.

In response to an information request from the PUB, in the record as PUB/MPA 1-004(a), MPA calculated the impact on various Plans of altering energy price assumptions while holding economics and capital variables at Reference assumptions. The following is a reprint of those outputs:

Figure 9. Excerpt from PUB/MPA1-004(a)

PV of Domestic Revenue
Comparison of Sensitivity to Energy Scenarios
Economic and Capital Scenarios at Reference
(in millions)

	6.00% Discount Rate					10.00% Discount Rate				
	Plan 1	**Plan 4**	**Plan 6**	**Plan 12**	**Plan 14**	**Plan 1**	**Plan 4**	**Plan 6**	**Plan 12**	**Plan 14**
High	$44,107	$41,868	$42,317	$42,409	$41,991	$23,441	$22,810	$22,991	$23,274	$23,268
Reference	$43,791	$42,878	$43,301	$44,727	$44,230	$23,623	$23,476	$23,633	$24,285	$24,148
Low	$43,695	$44,192	$44,585	$47,375	$47,037	$23,724	$24,017	$24,169	$25,122	$25,037
Sensitivity from Low to High	0.94%	-5.26%	-5.09%	-10.48%	-10.73%	-1.19%	-5.02%	-4.87%	-7.35%	-7.06%

In our work on the 2013 Plans, we concluded that energy prices had an inverse relationship to Manitoba ratepayer costs for those Plans which included Keeyask and Conawapa, but not necessarily for the All Gas Plan. In other words, High energy prices would lead to lower Manitoba ratepayer costs in the Plans based on the Keeyask and Conawapa projects.

One reason for this relationship is the higher export emphasis of those Plans. Recall that “energy prices” in the Manitoba Hydro scenarios consisted of a complex of four variables: electricity export prices (to the MISO market), electricity import prices (from the MISO market), natural gas prices (at delivered cost to Manitoba natural gas-fired electricity facilities), and carbon costs (as potentially imposed on fossil fuel-burning electricity generation facilities in the future). As these prices rise (in concert, as per Manitoba Hydro), Plans which include more gas-fired generation would suffer from higher natural gas fuel costs. On the other hand, Plans which emphasize hydroelectric production would not be affected by natural gas prices, but would benefit from higher export prices in the MISO market. Over the course of a 48-year model the picture is complicated by the fact that hydrology is different every year, and in droughts the impact of energy prices is reversed across Plans (high prices are bad for hydroelectric Plans in a drought because imports will be more expensive). However, since droughts are a relatively infrequent occurrence, they do not dominate the average impact across Plans.

Table 3 (below) compares the role of exports in the 2013 versions of the Plans with the role of exports in the updated versions (calculated from the 6% NPV figures).

Table 3. Export as % of Total Revenues – 2013 vs. Updated Plans

	All Gas	2	4	5	6	PDP
2013 Version	8.6%		14.2%		13.8%	17.3%
2014 Version	13.9%	16.1%	20.2%	21.4%	21.1%	27.5%
Change	+ 5.3%		+ 6.0%		+ 7.3%	+ 10.2%

The significant increases in revenues from exports for Manitoba Hydro across all of the updated Plans result from the much lower domestic demand in Manitoba due to Level 2 DSM programs. The updated All Gas Plan has an export orientation as strong as the 2013 versions of Plans 4 and 6. The updated versions of Plans 4 and 6 are now almost 50% more export oriented, and in fact are projected to generate more revenue from exports that the 2013 version of the PDP.

This suggests that ratepayer costs in all of the updated Plans are inversely proportional to energy prices, and likely quite strongly inversely proportional.

2.5. Inter-generational Impacts

In section 2.3. above, the depiction of rate paths for different Plans suggest strongly diverging treatment of Manitoba ratepayers over time.

- Regardless of the Plan chosen, ratepayers will face the maximum allowable rate increase for the next fifteen years under all Plans.
- After approximately 2030, the Plans diverge fairly dramatically, and continue to diverge for decades to come.

2.5.1. NPVs for Shorter Periods

MPA calculated the NPVs for domestic ratepayer costs for periods of 20 years and 30 years, as well as for 48 years. Figure 10 (below) presents these calculations for a 3.8% annual maximum rate change per year.

Figure 10. NPV of Ratepayer Costs for Alternative Periods

Present Value of Domestic Revenue
Reference Economics, Energy and Capital
20 year, 30 year and 48 year periods
($ in millions)

	All Gas	Plan 2	Plan 4	Plan 5	Plan 6	PDP
Present Value						
NPV @ 6.00%						
2015 - 34	$24,244	$24,094	$24,911	$24,965	$24,993	$25,212
2015 - 44	$31,014	$31,728	$32,111	$32,314	$32,407	$34,694
2015 - 62	$39,659	$40,284	$39,440	$39,636	$39,696	$41,999
NPV @ 10.00%						
2015 - 34	$17,224	$17,133	$17,572	$17,599	$17,612	$17,721
2015 - 44	$19,900	$20,149	$20,440	$20,526	$20,566	$21,488
2015 - 62	$21,999	$22,248	$22,225	$22,312	$22,345	$23,322

A variety of observations can be made from this data:

- In the first 20 year period, Plan 2 is actually the least costly for ratepayers. This is likely the case because it does not involve writing off the costs sunk into Keeyask (as the All Gas Plan does), while new spending on Keeyask occurs relatively late in the period.
- The All Gas Plan represents the lowest ratepayer cost if the period examined is 30 years. In fact, the gap between the All Gas Plan and Plans 4, 5 and 6 is actually wider at 30 years than at 20 years, and the gap between All Gas and the PDP is also at its widest point.
- The gap between All Gas and Plans 4, 5 and 6 is never more than approximately 4%, regardless of the discount rate selected.
- When the examined period is 48 years, Plans 4, 5 and 6 have caught up to or surpassed the All Gas Plan, which suggests that ratepayers in that final 18 year period are dramatically better off under Keeyask-based Plans.
- While the PDP has the highest ratepayer costs under all periods, the gap narrows considerably over time. If the model were to progress beyond 48 years, then it is likely that the ranking of the PDP would continue to improve in nominal dollar terms. However, depending on the discount rate selected, the PDP might never catch up to Plans 4, 5 and 6. Higher discount rates dramatically reduce the present value effect of results so far in the future.
- From an inter-generational perspective, choice of Plans (considered solely from the perspective of ratepayer costs) is largely irrelevant to people who are likely to be ratepayers only for the next 15 years (e.g., older ratepayers, or businesses that do not foresee a long-term future in the province). However, beyond that point, the choice of Plans can have a very significant impact. Generational burdens, and the likely competitiveness of Manitoba electricity rates, will be very different depending on the choices made.

2.5.2. PUB Rate-setting Impacts

As noted above, MPA ran a financial model at both a 3.8% maximum annual change in domestic rates and a 4% annual maximum change. While the model was originally constructed to allow a maximum annual change of two times the projected rate of inflation (i.e., 2 x 2% = 4%), since the projected rate of inflation was previously 1.9% we ran the model both ways to ensure that comparisons could be made with previous results.

It is apparent that the setting of rates has important impacts on both total costs to ratepayers, intergenerational allocation of ratepayer costs, and the financial health of Manitoba Hydro.

In order to more clearly illustrate these issues, we ran the model at a maximum annual change in domestic rates of 5% for Plan 5 and the PDP. This is two and one half times the projected long-term rate of inflation, and represents a significant and noticeable annual increase in rates. At 5% growth per year existing rates would double in 15 years, and triple in 23 years, as compared to 18 and 29 years respectively for a 4% annual increase.

Figure 11. Manitoba Ratepayer Costs at 4% and 5% Maximum Annual Rate Change

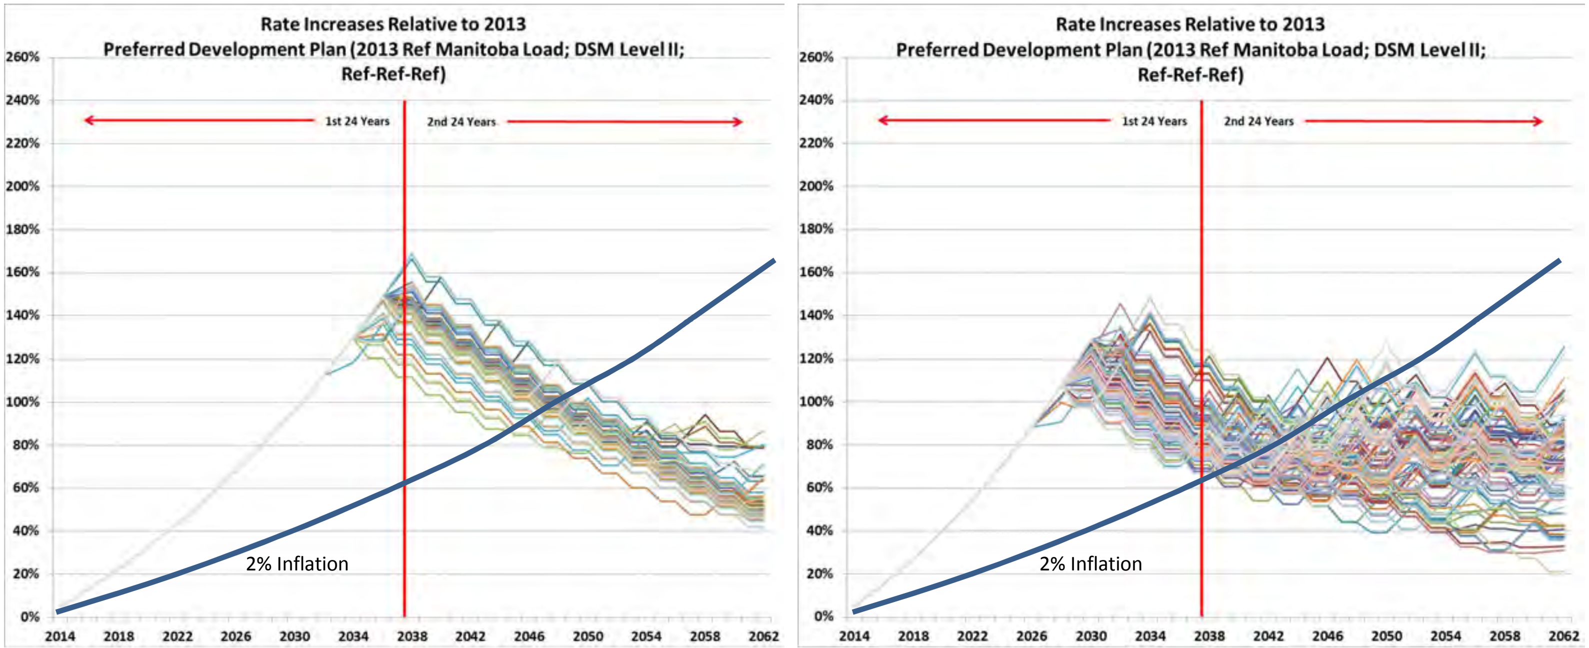
Standard Deviation	$4,423	$4,422	$3,113	$4,823

- As can be noted from the Figure, NPV results do not change dramatically for either Plan as a result of adopting a higher maximum annual rate change. While rates are rising faster in the early years of the model, the process of discounting the future (which makes earlier ratepayer costs more important) offsets the benefits achieved by Manitoba Hydro more quickly recovering costs.

- In nominal dollar terms, raising rates by 5% per year has a significant impact, particularly for the PDP, which sees total nominal dollar ratepayer costs fall by approximately 4% over the life of the model. At very low discount rates, this effect would also be noticeable.

Rate charts illustrate the impact of increasing the maximum allowed annual rate change.

Figure 12. Comparison of PDP Rate Paths with 4% and 5% Maximum Annual Rate Change Rule

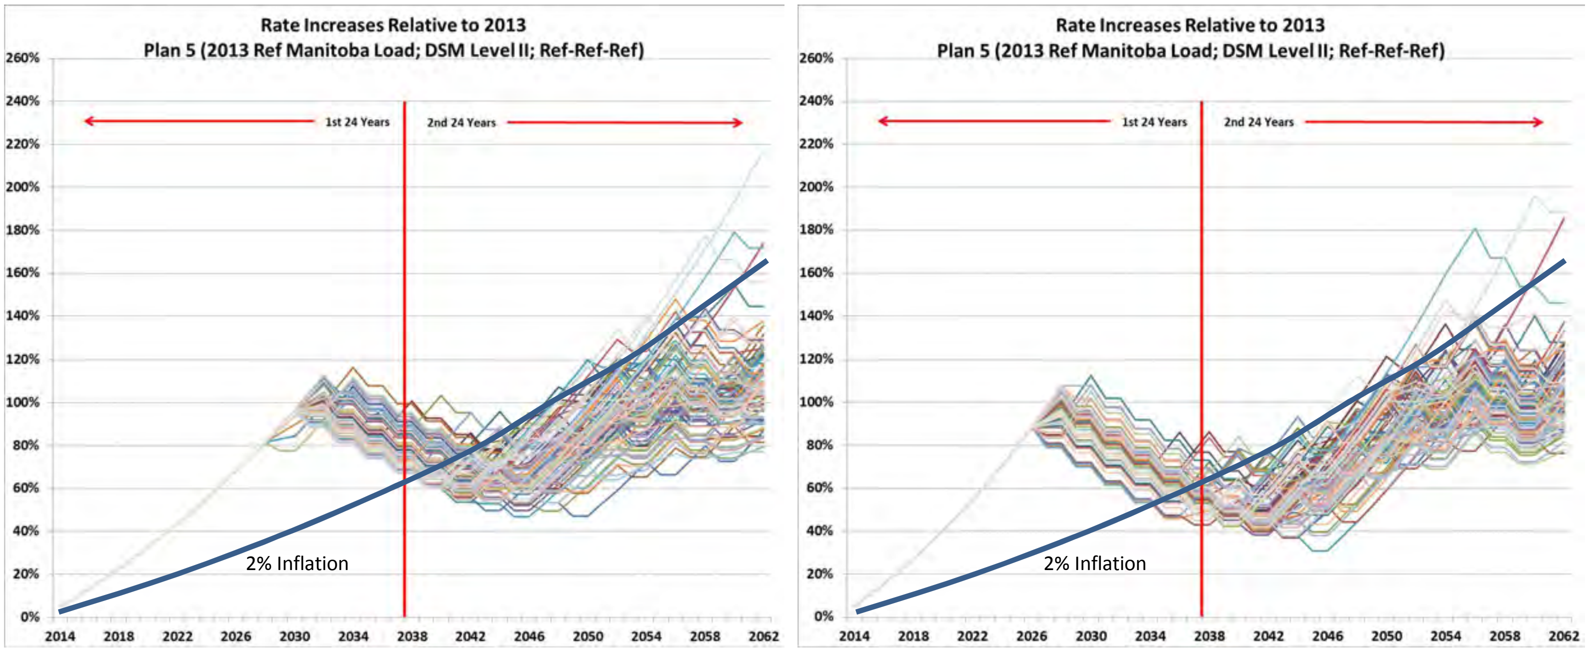


It is apparent from these graphs that raising rates at 5% per year versus 4% has a dramatic impact on rate path. While under 5% annual rate increases a doubling of rates is reached sooner, the rates peak earlier and at a lower absolute level before declining. The logic behind these differences centres on the fact that Manitoba Hydro would be generating significantly more revenue in the early years of the Plan, and hence would be taking on less debt, paying less interest over time, and more quickly paying down debt principal, which allows rate declines to be implemented.

Interestingly, the 5% graph demonstrates greater sensitivity to hydrological patterns (since the 99 lines are spread more widely after 2040). In the 4% graph, the spreading of the lines appears to begin in about 2055, suggesting that if the model were continued further into the future, a similar phenomenon would take place.

From an inter-generational perspective, the 5% path demonstrates more clearly than ever that the economic trade-off between ratepayers at different points in the future is crucially affected by the PUB's rate-making policies.

Figure 13. Comparison of Plan 5 Rate Paths with 4% and 5% Maximum Annual Rate Change Rule



For Plan 5, the cumulative rate impact of allowing 5% annual rate changes rather than 4% is less immediately apparent than for the PDP. However, it is clear that the first rate peaks occur earlier in the 5% case, and that the subsequent rate decline is deeper before rates resume their upward trajectory. For example, in 2038, rates in the 4% case are between 60% and 100% above the initial level, while in the 5% case rates are only 60% to 80% above the initial level.

Finally, it is interesting to note that after reaching their bottom, both rate paths essentially begin to follow an upward trajectory roughly consistent with inflation. This is very likely to be a reflection of the inflation-based assumptions embedded into the model further into the future. It perhaps suggests the essentially mechanical nature of the modeling exercise beyond the limits of the projects that can actually be planned in detail today.

2.6. Government Revenues

An important element of the review of the alternative Plans is the revenue that they are expected to deliver to the Government of Manitoba.

Government revenues were projected based on the 3.8% maximum annual rate change rule so that figures would be comparable to earlier modeling. Outputs are provided at a 6% discount rate, a 3% discount rate (which approximates the government's own cost of funds), and in nominal dollars.

Water Rental	$2,628	$2,780	$2,928	$2,931	$2,928	$3,207
Capital Tax	$2,635	$3,147	$3,166	$3,209	$3,207	$4,021
subtotal	*$5,263*	*$5,927*	*$6,094*	*$6,139*	*$6,135*	*$7,228*
Debt Guarantee Fee	$3,987	$4,642	$4,565	$4,701	$4,671	$5,646
Total	*$9,250*	*$10,569*	*$10,659*	*$10,840*	*$10,807*	*$12,874*
Nominal Dollars						
Water Rental	$5,103	$5,506	$5,745	$5,749	$5,744	$6,472
Capital Tax	$5,490	$6,679	$6,494	$6,572	$6,573	$8,440
subtotal	*$10,593*	*$12,185*	*$12,239*	*$12,320*	*$12,317*	*$14,912*
Debt Guarantee Fee	$7,998	$9,430	$8,561	$8,813	$8,727	$10,278
Total	*$18,591*	*$21,615*	*$20,800*	*$21,133*	*$21,045*	*$25,190*

Unsurprisingly, the PDP provides the Government with the most revenue: across each revenue source individually, in total, and regardless of the discount rate calculation. This should be expected since the PDP uses the most water, the most capital, and the most debt of all of the Plans.

From the Government's perspective, however, the benefits of additional revenue from Manitoba Hydro must be balanced against the higher costs to ratepayers that result from the PDP, and the potential economic drag that may result from those higher rates (higher costs for a staple such as electricity is roughly the equivalent of a reduction in disposable income for individuals and businesses, which results in lower tax revenue to the Government from sources other than Manitoba Hydro).

Government revenues can also be compared as between the 2013 versions of the Plans, and the updated versions.

Table 4. Government Revenues at 6% Discount Rate Ref/Ref/Ref – 2013 vs. Updated Plans

	All Gas	2	4	5	6	PDP
2013 Version	$5,866		$6,733		$6,775	$8,061
2014 Version	$5,486	$6,117	$6,437	$6,545	$6,531	$7,619
Change	- 6.5%		- 4.4%		- 3.6%	- 5.5%

Across all of the Plans, government revenues have declined with the updates made. In addition, the relative size of the gap between the PDP and most of the other Plans has narrowed slightly. Nevertheless, a gap continues to exist.

3. The Impact of Droughts

In our response to PUB/MPA 1-027, MPA provided a detailed description of the projected consequence of a “challenging” hydrological pattern. This pattern included two significant periods of drought, as well as a generally low average hydrology over an extended period of time.

In order to consider the impact of the updates made to the Plans, the same hydrological pattern was examined. Only the Ref/Ref/Ref scenario can be properly compared, as data for other scenarios (and in particular High and Low energy scenarios) has not been provided by Manitoba Hydro. Maximum annual rate changes are maintained at 3.8% to avoid adding a further difference.

Note that in the IR noted above MPA examined All Gas, Plans 4, 6 and 12, and the PDP. With the updated 2014 information, a slightly different set of alternatives was tested: All Gas, Plans 2, 4, 5, 6 and the PDP.

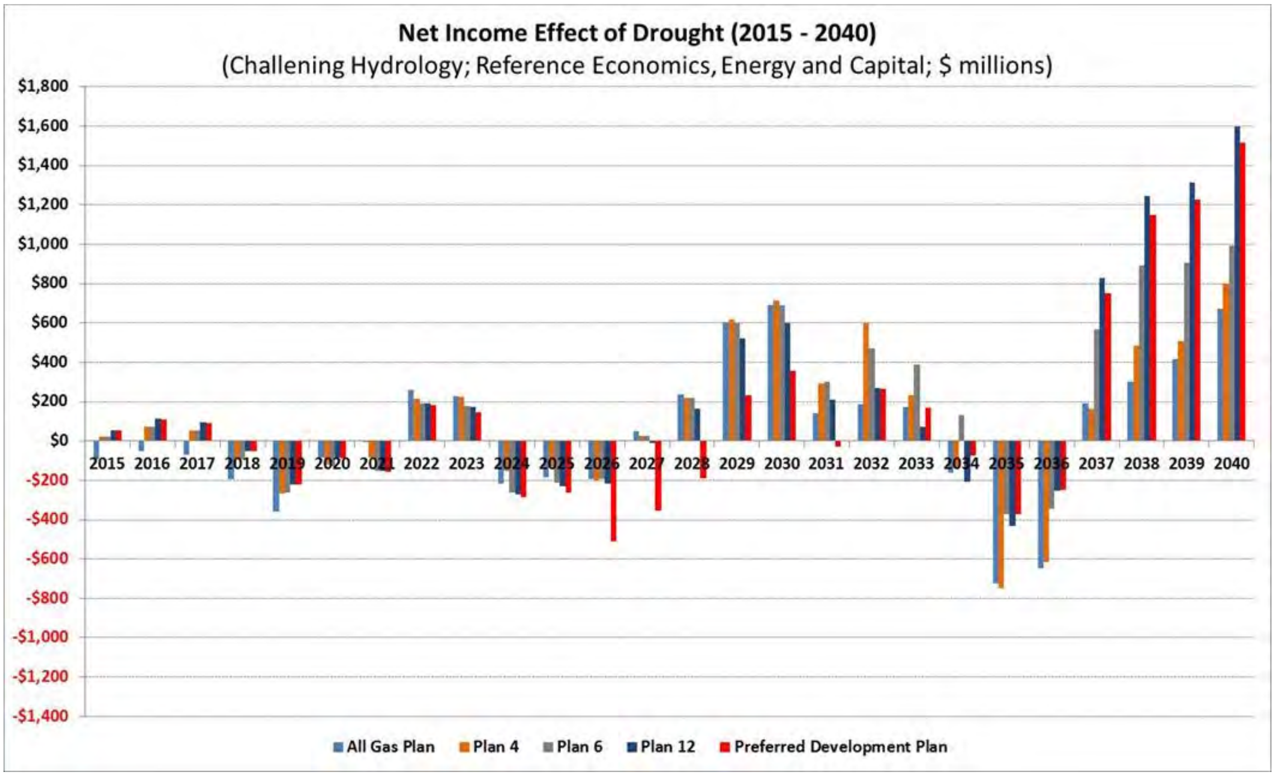
3.1. Net Income

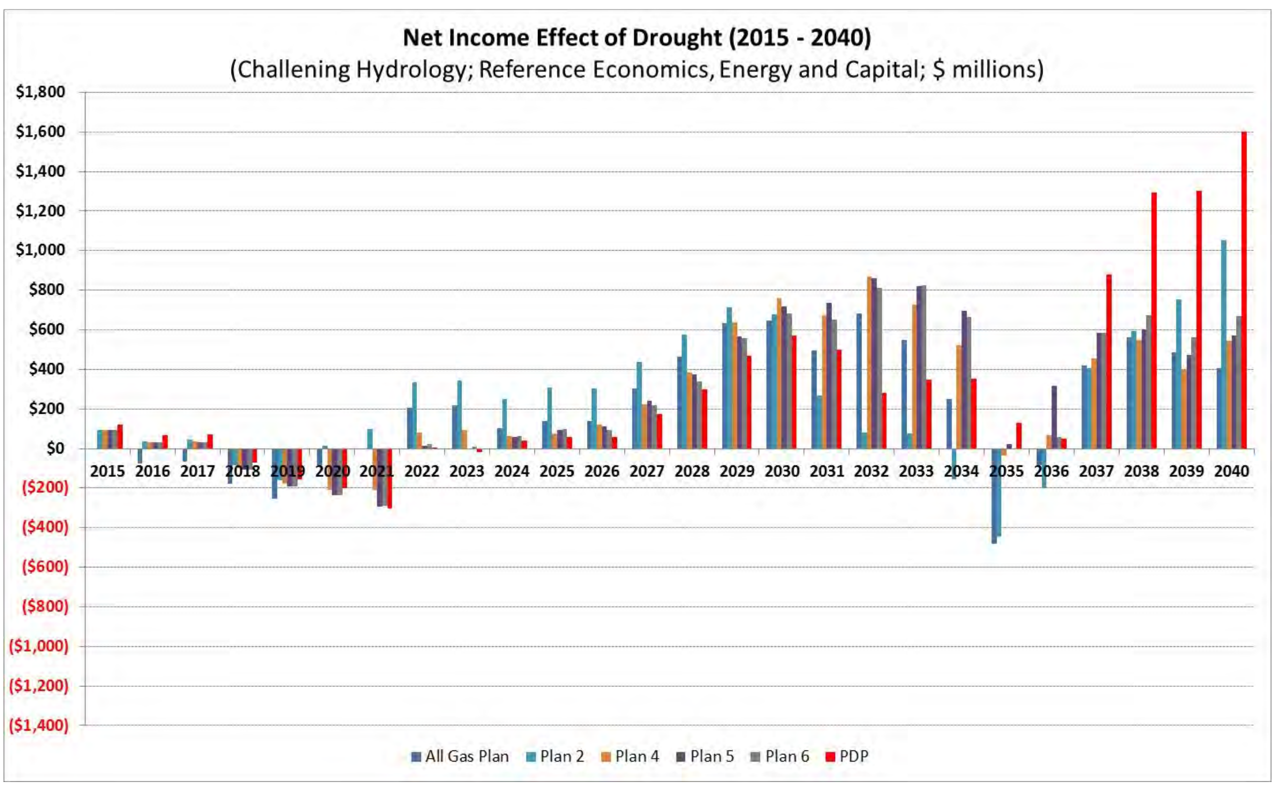
The following Figure compares the results of the 2013 Plans with the updated Plans.

Across all Plans it is immediately apparent that financial performance is now stronger. With the updated Plans, Manitoba Hydro is far less likely, even under very challenging hydrological conditions, to suffer negative net income. After 2021, only the All Gas Plan and Plans 1, 2 and 4 have any years with negative net income, notwithstanding the fact that Manitoba Hydro is presumed to be facing serious drought years in this projection.

A lower debt burden resulting from delayed generation projects (as compared to the 2013 versions of the Plans) clearly plays a role in these results.

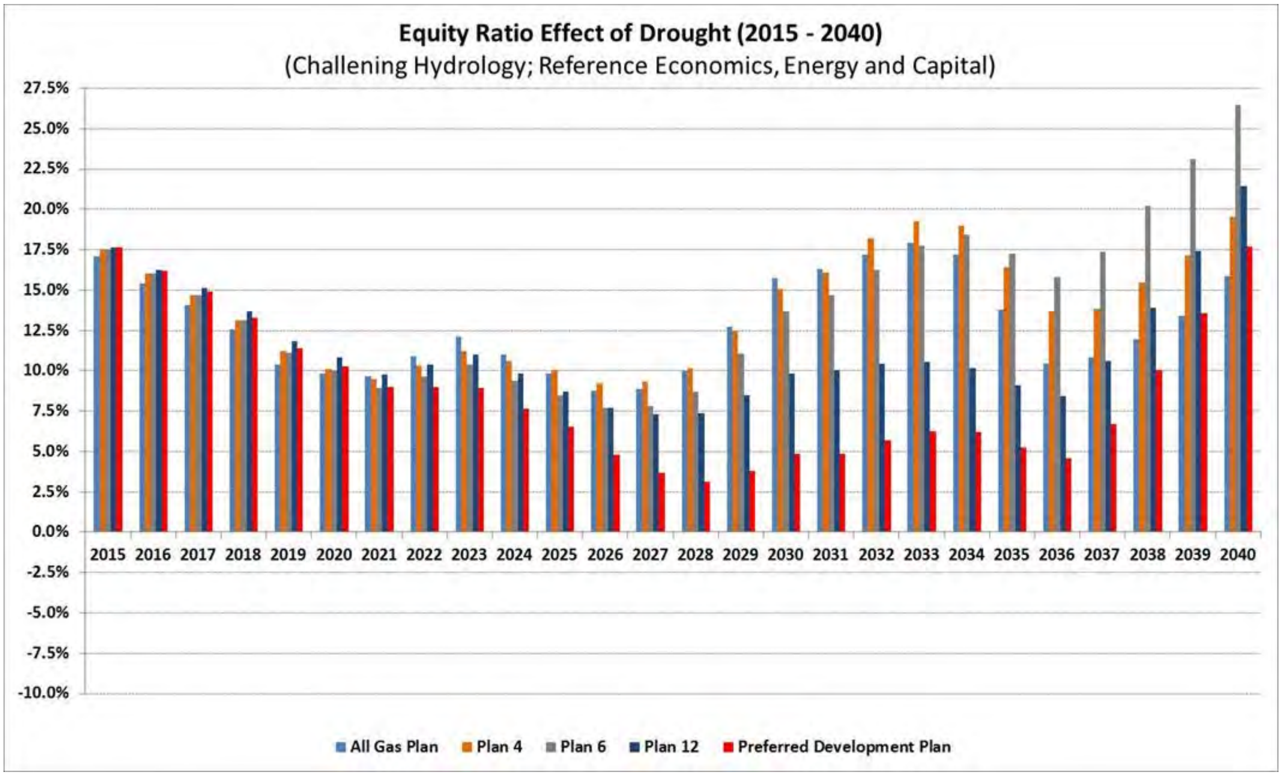
Figure 15. Net Income Performance Under Challenging Hydrology – 2013 vs. 2014

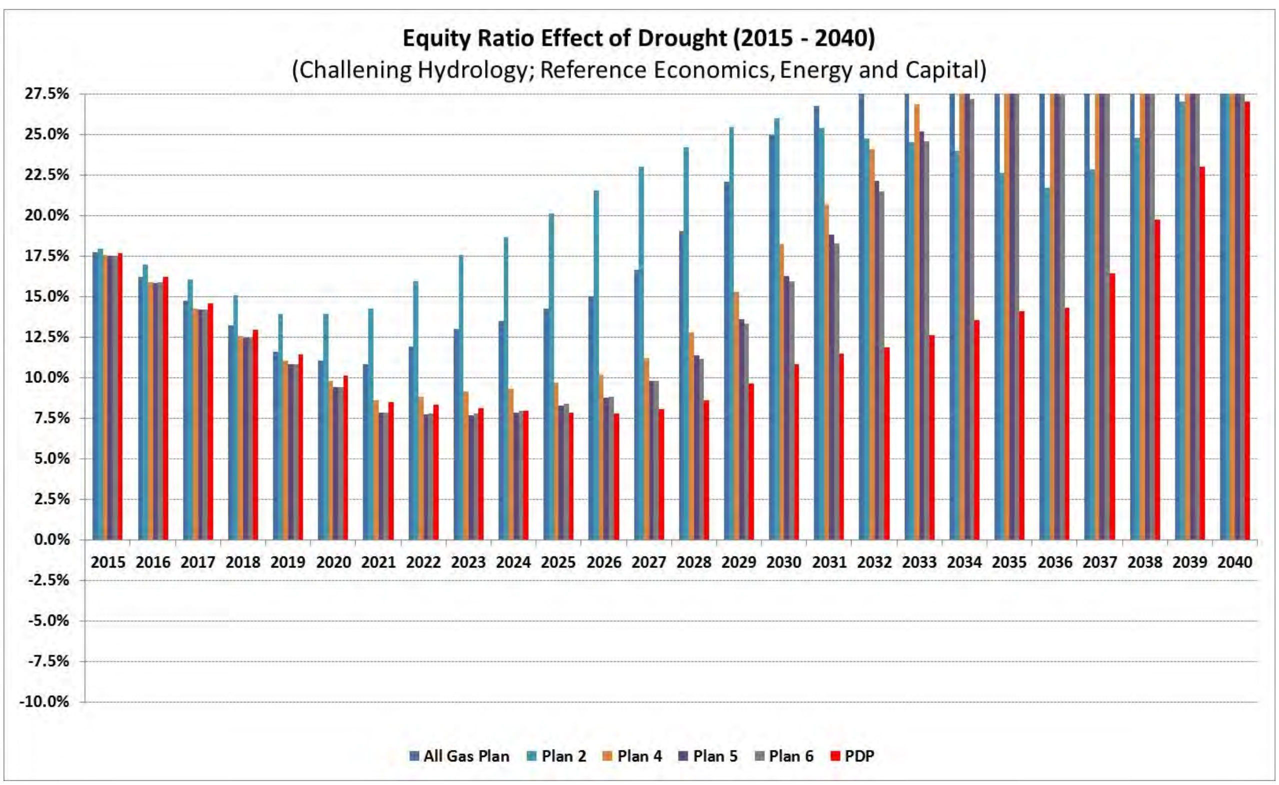




3.2. Equity Ratio

Figure 16. Equity Ratio Given Challenging Hydrology – 2013 vs. 2014





Note that Manitoba Hydro's equity ratio target is 25%.

The equity ratio results for the updated versions of the Plans are consistent with net income performance:

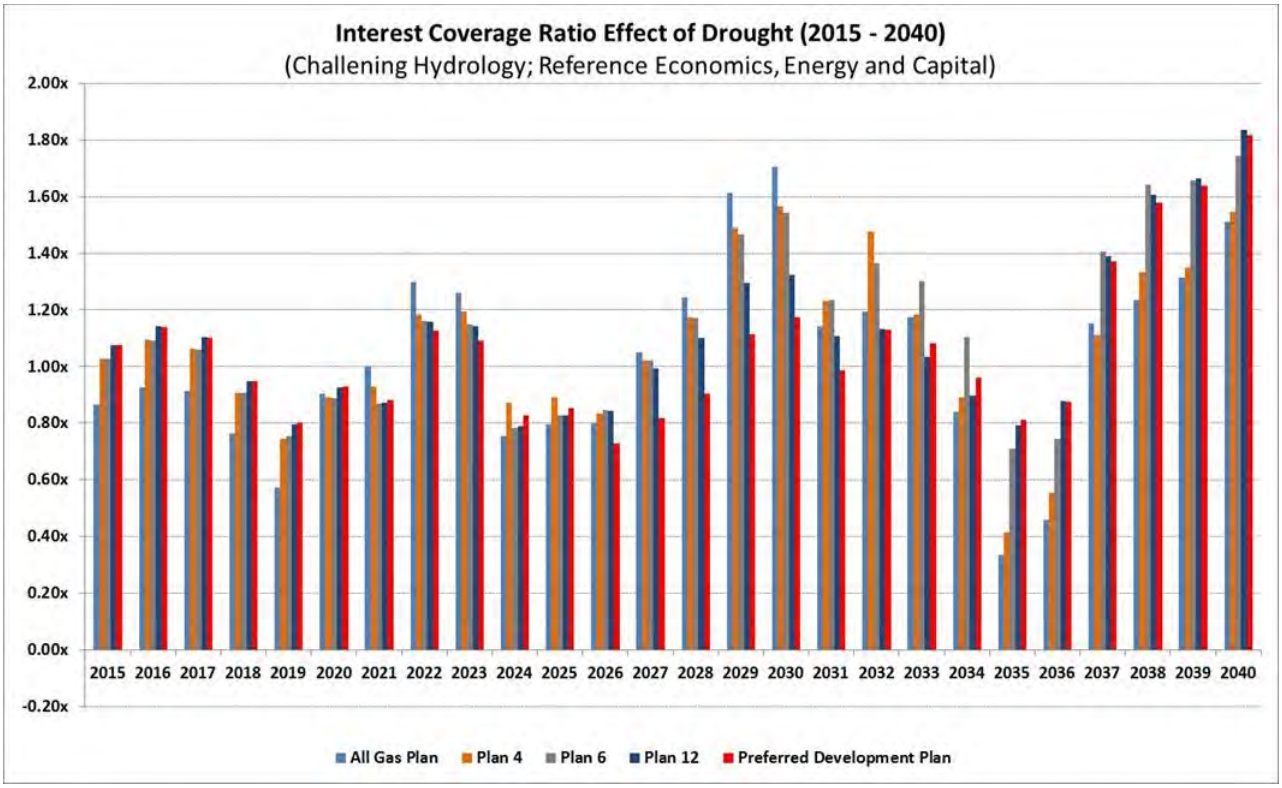
- For many of the Plans, the target equity ratio is met within 20 years, even under this challenging hydrology scenario.
- The PDP does not meet its equity ratio until 2040, but while its equity ratio falls below 10%, it never drops below 5%, as it did with the 2013 version of the Plan.
- For Plans 4, 5 and 6, the equity ratio is below 10% for less than a decade before improving strongly.

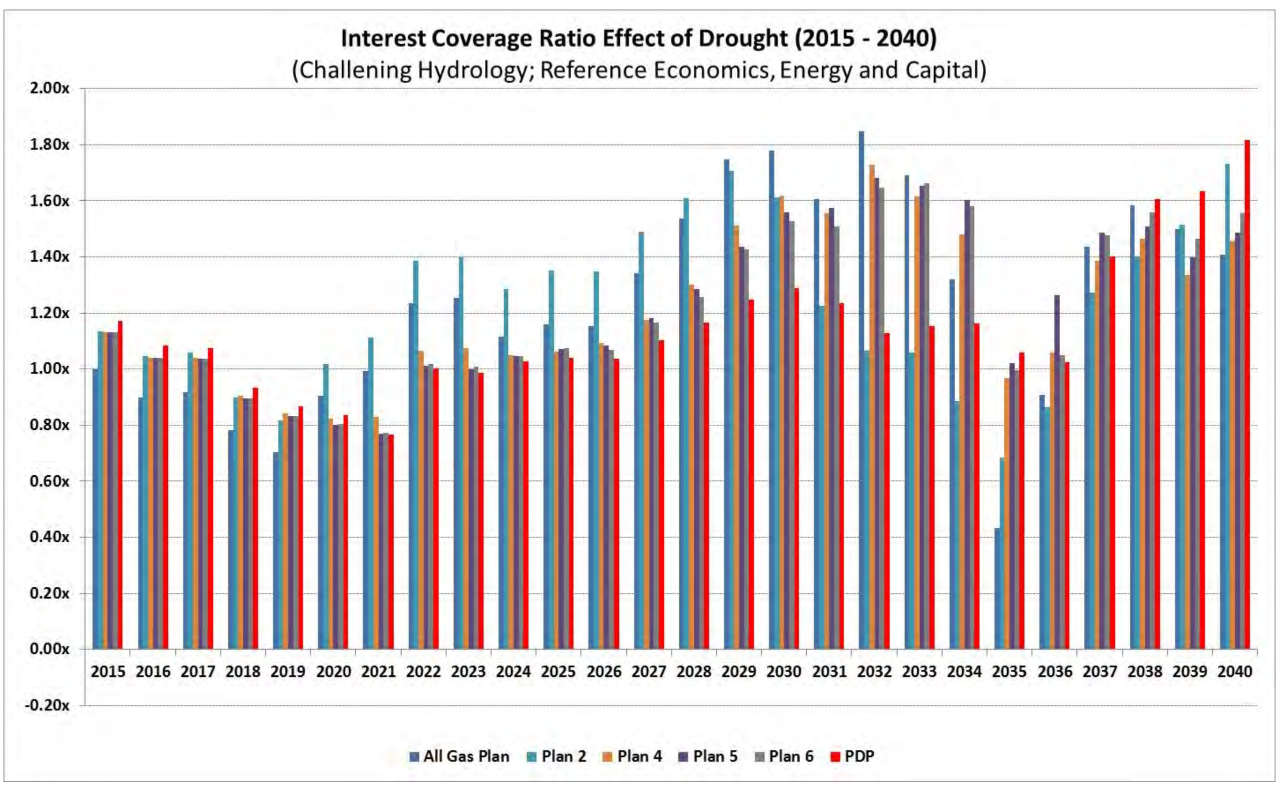
3.3. Interest Coverage Ratio

The improvement of the 2014 version of the Plans can be readily seen in the interest coverage ratio projection as well.

The 2013 versions of the Plans resulted in at least 10 years of interest coverage ratio below 1x for all Plans. In a few instances Plans actually fell below 0.5x for brief periods. The 2014 versions of the Plans are more robust, with few having interest coverage ratios below 1x for more than 5 years, and only one falling to 0.5x for a single year.

Figure 17. Interest Coverage Ratio Given Challenging Hydrology – 2013 vs. 2014





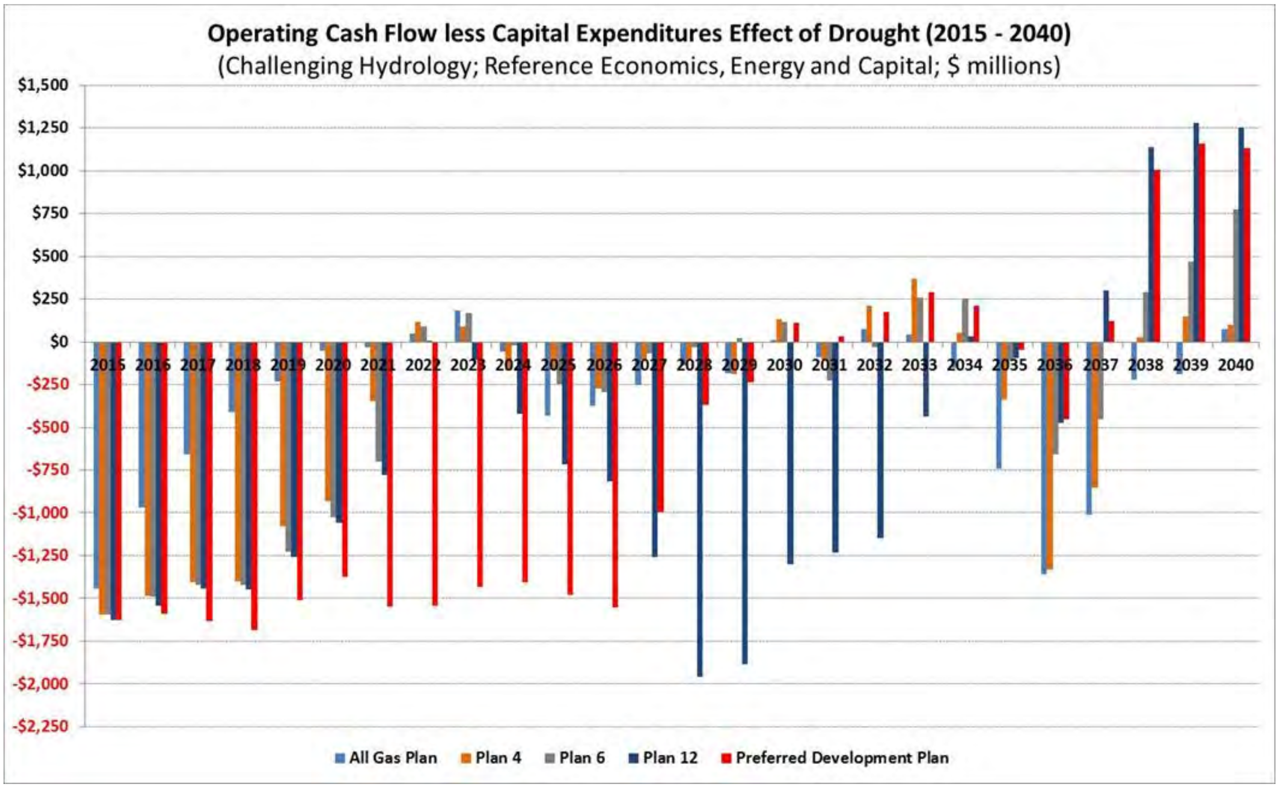
3.4. Operating Cash Flow Less Capital Expenditures

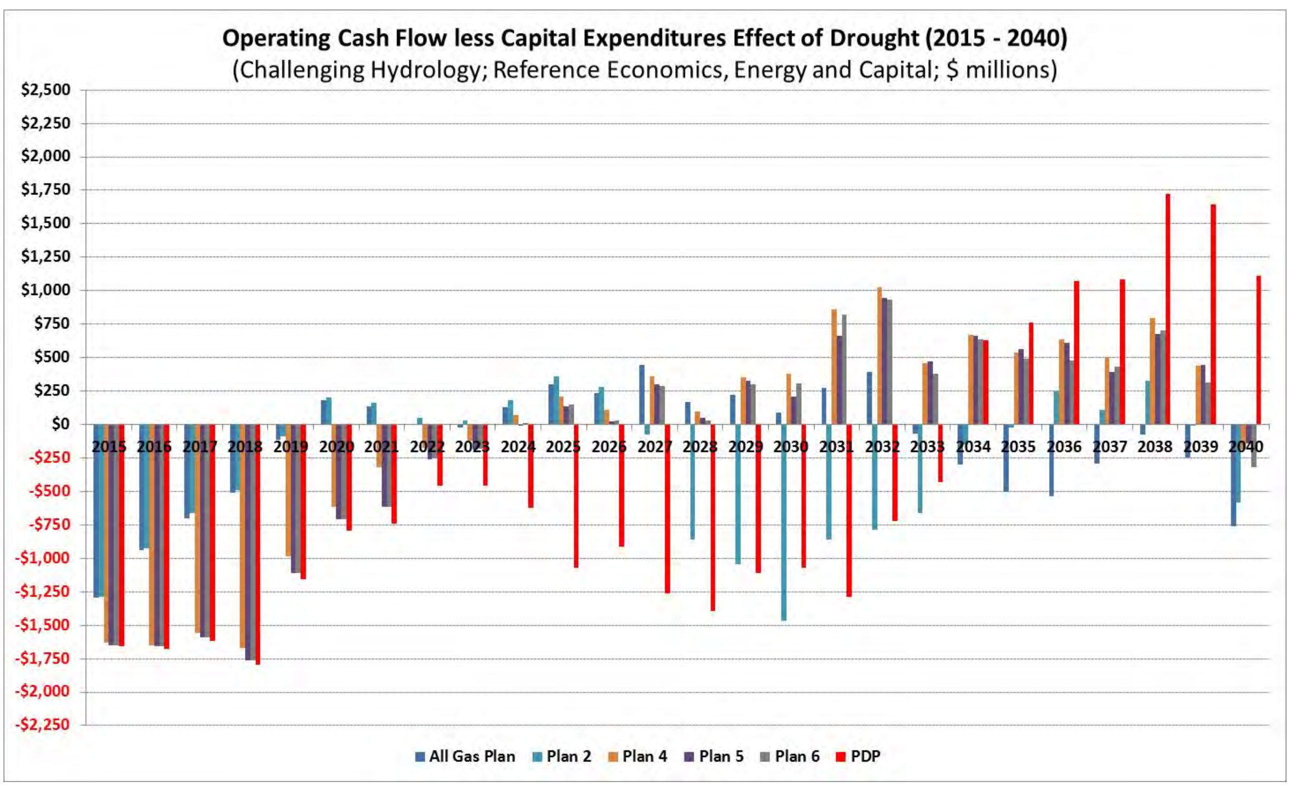
The principal financial difference between the 2013 and 2014 versions of the Plans is demonstrated by the calculation of cash flow less annual capital expenditures. The 2014 versions of the Plans require far less debt to be accumulated over time, across all Plans. This results in less debt, and hence less interest cost.

In addition, the repayment of debt principal begins much earlier in all Plans.

Despite a very challenging hydrology pattern, the 2014 versions of the Plans indicate no significant risk of perceived financial distress in a Ref/Ref/Ref scenario.

Figure 18. Cash Flow Less Capital Expenditures Given Challenging Hydrology – 2013 vs. 2014





3.5. Sensitivity

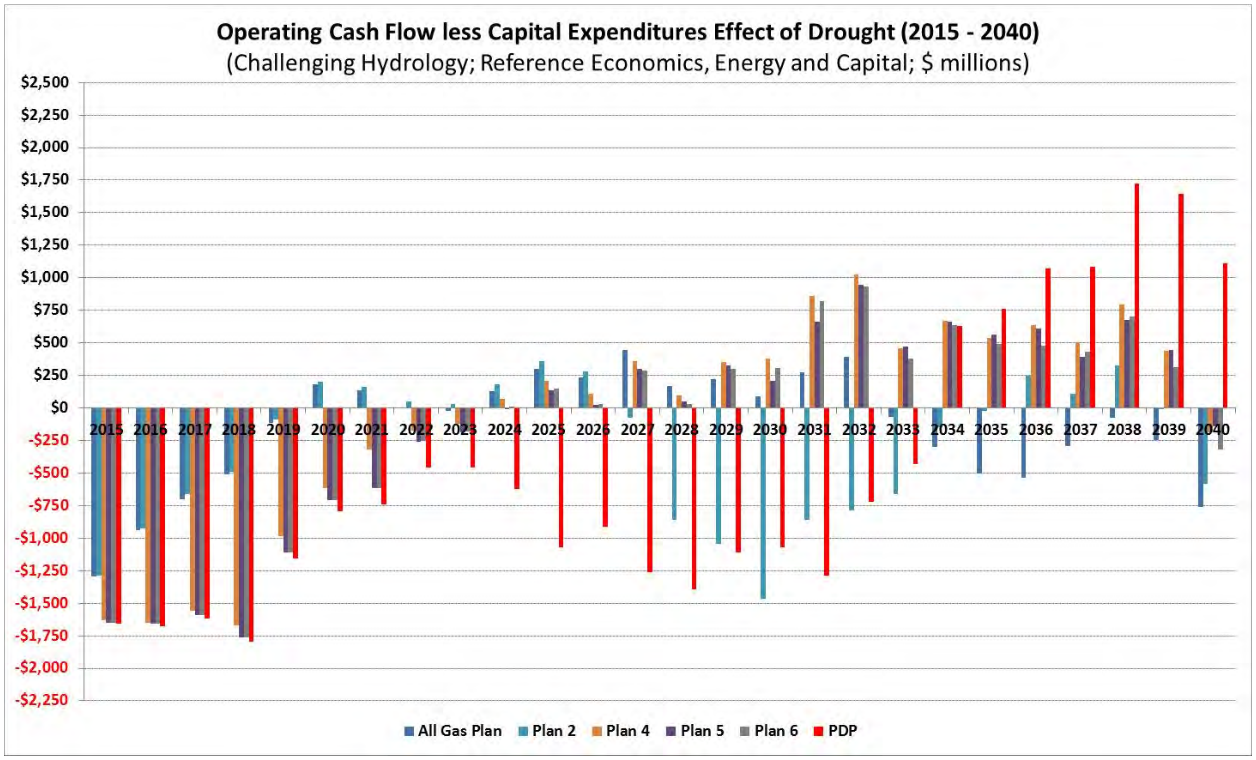
As was noted above, without detailed SPLASH model outputs it is not possible for MPA to produce valid projections in alternate scenarios. However, we were able to test Manitoba Hydro’s financial performance under this challenging hydrology pattern based on the sensitivities described above. Two examples appear to provide useful insights.

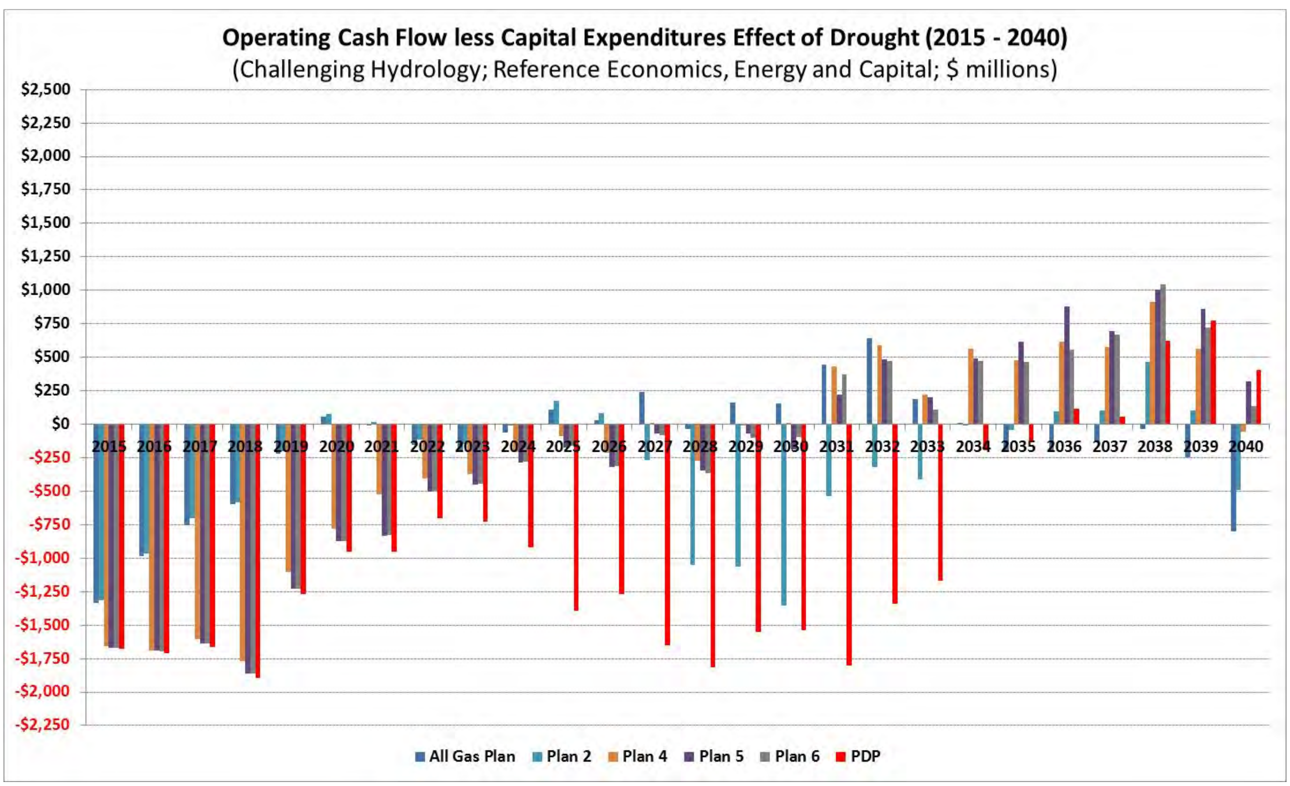
3.5.1. Higher Interest Costs

Increasing the rate of interest applied to Manitoba Hydro increases its net costs, reduces net income, and reduces its operating cash flow. The financial effect is similar to a reduction in revenue that might be caused by lower export prices.

In the challenging hydrology environment presented here, a one percent increase in interest rates causes all of the financial indicators to deteriorate. A comparison is provided below between the performance of the updated 2014 Plans at Ref/Ref/Ref and the same Plans at an interest rate one percent higher than projected in the Ref/Ref/Ref scenario.

Figure 19. Cash Flow Less Capital Expenditures Given Challenging Hydrology – Base vs. +1%





The effect of increasing the interest rate by 1% is reduced cash flow across all Plans.

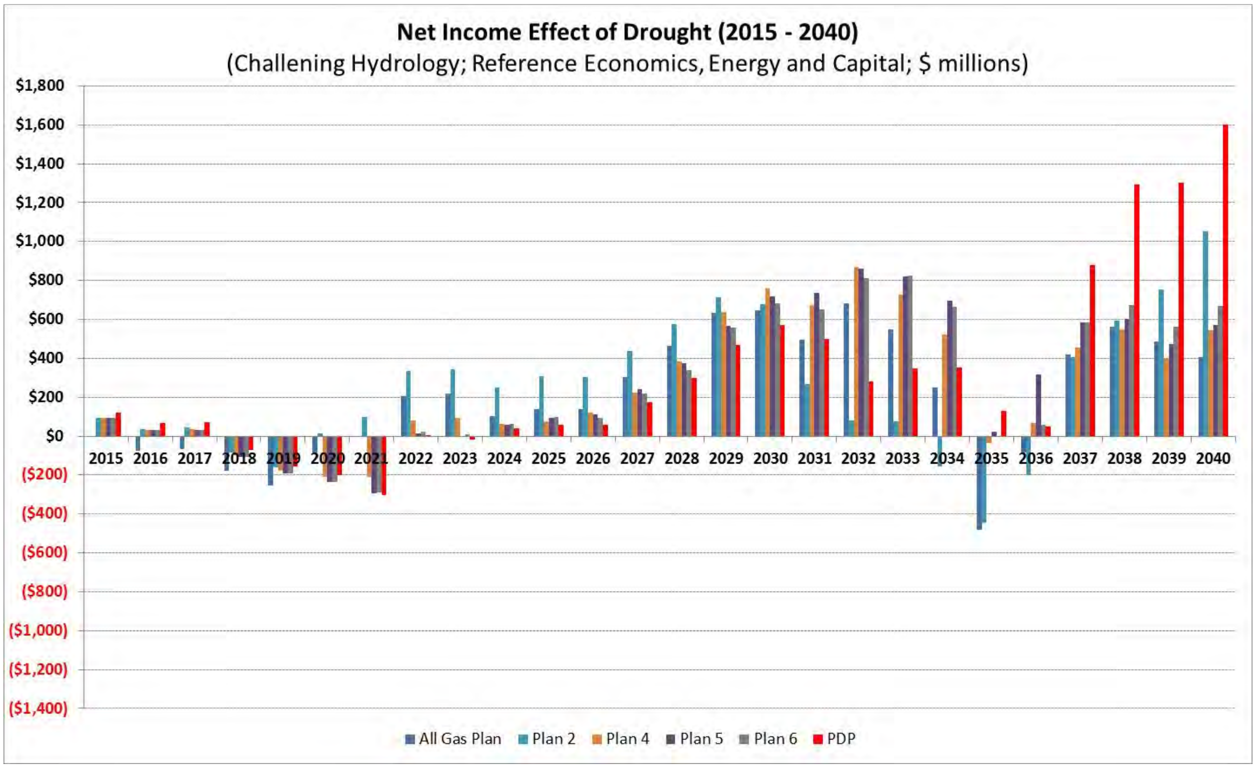
Those Plans that have greater capital requirements, and in particular the PDP, are particularly affected by the change in interest rates. Since the same Plans that are more capital intensive are more sensitive to export prices, as noted above, it should be assumed that a decline in export prices below the Reference projection would similarly affect the same Plans to a greater degree.

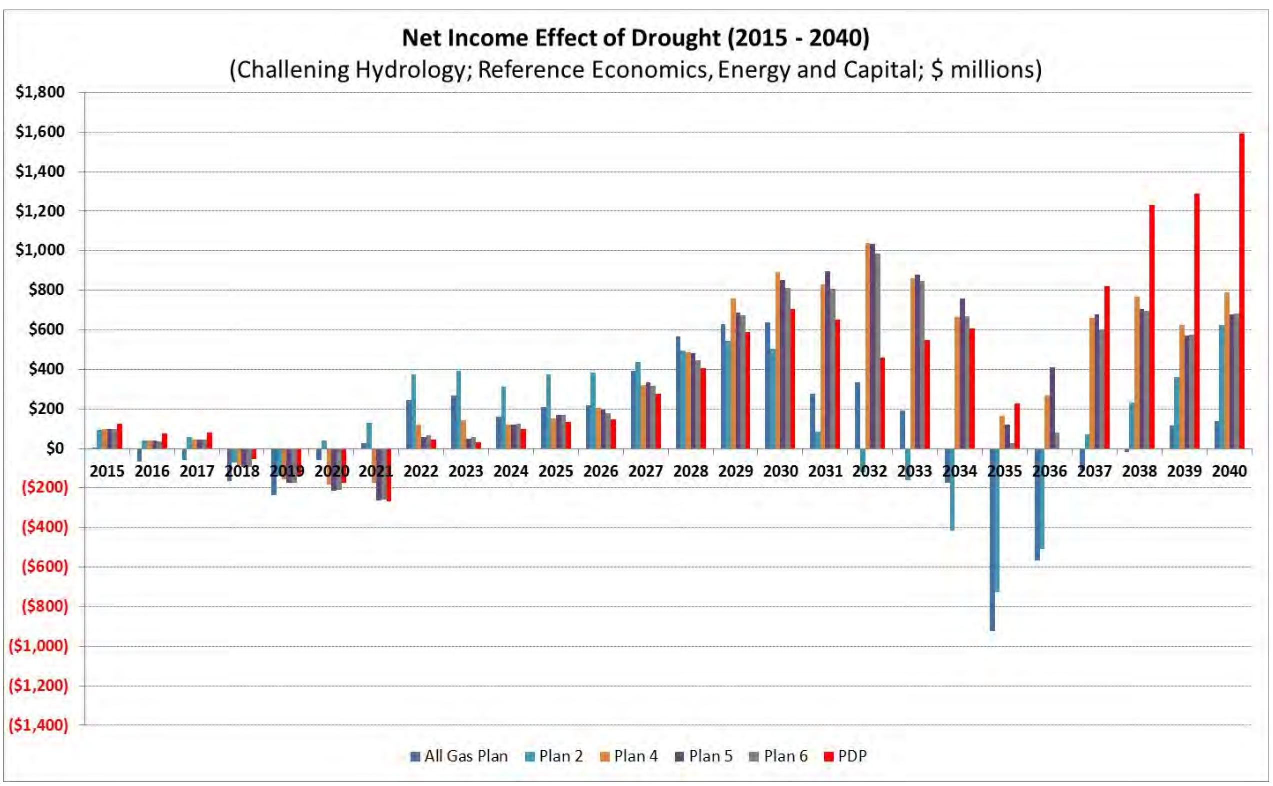
It is notable that cash flow in some Plans actually improves under the higher interest rate case in the late years of the model depicted on the graph. This is a result of the relationship between rate increases and the timing of droughts: in a lower interest rate environment, robust financial health at Manitoba Hydro allows for lower Manitoba domestic rates and greater reliance on exports. When drought sets in and exports are curtailed, however, this means that a greater drop in revenue results, and the limitation on the maximum rate increase subsequent to the drought limits the ability of Manitoba Hydro to quickly recover its financial position. In a higher interest rate environment, rates would not have been declining as rapidly, so the onset of drought would not have as great an impact on the company's finances, and recovery would be more rapid after the fact.

3.5.2. Higher Maximum Rate Increases

The financial robustness of Manitoba Hydro in the face of drought is to some degree in the hands of the PUB through its rate-setting policy. As part of its modeling exercise, MPA calculated the projected performance of Manitoba Hydro in the face of drought at both maximum annual rate changes of 3.8% and 4.0%. The impact of this difference is depicted below for the net income of the updated 2014 Plans.

Figure 20. Net Income Given Challenging Hydrology – 3.8% vs. 4% Maximum Annual Rate Increase

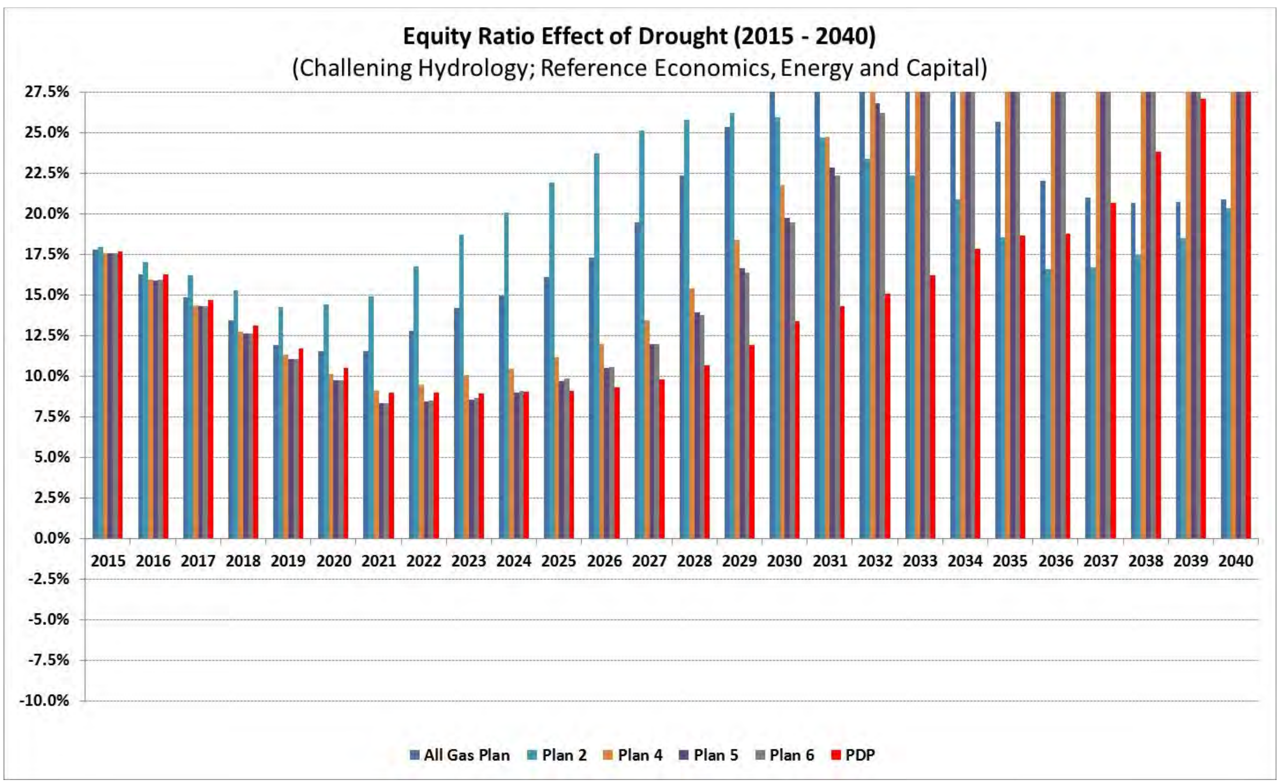




While the difference between a 3.8% maximum change in rates and 4% is small, it is nevertheless noticeable beginning in about 2020. Across all Plans net income rises to higher levels in the 2020s, as does cash flow, reducing the amount of debt that Manitoba Hydro must carry. By the early 2030s net income has improved by approximately $200 million per year for most Plans.

As can be recalled from Figures 4, 5 and 6, above, the difference between maximum rate changes of 3.8% and 4% allows domestic rates to peak earlier and then begin to decline. Given the mid-2030s timing of the major drought in this particular hydrological pattern being examined, several of the Plans would be caught by the limitation on rate increases. For example, Plan 1 would have had declining rates beginning in the late 2020s, but when the drought hits, the model only allows rate increases of 4%, despite very significant declines in net income caused by the drought. As a result, Manitoba Hydro's financial position worsens dramatically for a few years before recovering. However, as the graph below demonstrates, this is not a major financial risk, because Manitoba Hydro's finances have already become robust by that point. Notwithstanding the sharply negative net income resulting from the All Gas Plan during the drought of the 2030s, Manitoba Hydro's equity ratio does not fall below 20%.

<u>Figure 21. Equity Ratio Given Challenging Hydrology – 4% Annual Maximum Rate Change</u>



This demonstrates that there is a direct trade-off between inter-generational concerns in rate-setting policies, and the financial robustness of Manitoba Hydro to withstand challenging hydrology and other financially threatening events. The differences between the Plans suggests that this flexibility should be relied upon if Manitoba Hydro ultimately pursues a Plan that has a higher capital intensity, and is therefore more likely to be subject to significant financial shocks from drought or other causes during the next 20 years.

4. Conclusions

4.1. Keeyask and the Intertie

Does the new information provided by Manitoba Hydro suggest that alternatives are now clearly commercially superior to proceeding with Keeyask and the transmission interconnection?

As shown in Chapter 2 above, the gap between the All Gas Plan and Plans which include Keeyask 2019 and a transmission intertie, has narrowed somewhat. The Plans are essentially identical in their ratepayer impact for the first 15 years, but in the second 15 years All Gas appears to have an advantage, which it then gives up in the final period of our financial model.

However, this gap is not large enough overall to appear to be significant, given all of the caveats about assumptions and precision that must be recognized in any long-term financial modeling exercise.

As was noted by MPA before the PUB, Keeyask and the transmission intertie are immediate, real, actionable projects, which in our view should not be dismissed without clear evidence of commercially superior alternatives. Neither the All Gas Plan, nor Plan 2 (which does not include an intertie and schedules Keeyask for a later build) appear to satisfy that condition from the perspective of ratepayers.

From the government's perspective, the All Gas Plan provides the lowest revenues over time, and generates the least export revenue (in addition to fewer jobs and economic development, which is an issue outside our scope).

From the perspective of potential financial distress, neither the All Gas Plan nor Plan 2 can be demonstrated to be demonstrably different from Plans 4, 5 and 6 under a challenging hydrology scenario, as can be seen from the review of this issue in Chapter 3, above. While the exact timing of investments and potential drought or other distress events result in differences between Plans, it is not clear that there is any clear superiority or inferiority as between the Plans considered over a long period of time.

Based on this review of the new information, MPA sees no reason to modify our views as expressed before the PUB.

4.2. Conawapa

Does the new information provided by Manitoba Hydro suggest that Conawapa is now a more attractive development opportunity than alternatives, and therefore deserves expenditure of substantial resources to the exclusion of other opportunities?

As noted in section 2.1 above, the PDP is clearly inferior to Plans 4, 5 and 6 across all discount rates, including 0%. Increasing the maximum annual rate change from 3.8% to 4% does not change this conclusion. Even at a maximum rate change of 5% (2.5x the rate of inflation), Plan 5 is still superior to the PDP in a Ref/Ref/Ref scenario.

As has been noted in the past, the PDP is more sensitive to export prices and interest rates than other Plans. As a result, it is reasonable to believe that should interest rates fall below Reference projections, or export prices rise above Reference projections, then the gap between the PDP and alternatives could narrow.

From the government's perspective, it is unquestionable that the PDP delivers greater revenue than alternatives (as well as more jobs and economic development). However, does this benefit decisively outweigh the greater cost to Manitoba ratepayers that should be expected?

A final consideration is that according to the updated 2014 Plan presented by Manitoba Hydro, the PDP now contemplates Conawapa for an in-service date of 2031, with construction commencement more than 10 years away. Given this extended timeframe for continued development, it does not appear reasonable to assume that Conawapa should be an exclusive development priority superior to other alternatives.

MPA continues to support its comments to the PUB that Conawapa should be considered a development opportunity, competing with other potentially superior alternatives, and continued expenditures to develop Conawapa should be justified in that light.

Tab 22

BCG

REPORT

Review of Bipole III, Keeyask and Tie-Line Project

Manitoba Hydro Electricity Board

September 19, 2016

Introduction

This report summarizes the results of a review performed by The Boston Consulting Group ("BCG"), on behalf of Manitoba Hydro Electric Board("MHEB"), to evaluate the prudency and risk associated with Manitoba Hydro's ("Hydro") investments to build the Bipole III transmission project ("Bipole III"), the Keeyask generation station ("Keeyask"), and the MMTP/GNTL[1] projects ("Tie-line") [Exhibit 1]. The work was conducted between June and August 2016, using data provided by Hydro at the request of BCG, and through independent analysis performed by the BCG team based on its experience and expertise in the utility industry and with large capital projects.

The review performed sought to answer three key questions regarding the projects assessed [Exhibit 2]:

- Were the original decisions to invest the right ones to make?
- Is there further downside risk to the projects?
- Can the projects be stopped or paused without undue cost or risk?

Overview of Findings [**Exhibit 3**]

Through our analysis, we conclude that the decision to build a Bipole III was justified due to the significant and real reliability risks associated with relying solely on Bipole I, Bipole II, and Dorsey, and the societal impacts a catastrophic failure would carry. We also conclude that, while Bipole III East would have been the best option from an economic and execution standpoint, the decision to build along the West route was appropriate given the 2007 direction to the Chair of the Manitoba Hydro Electricity Board (MHEB) by The Minister of Hydro which deemed the East route inconsistent with environmental commitments and initiatives.

Conversely, the decision to build Keeyask and its associated infrastructure was an imprudent one due to a failure to fully assess the risks associated with moving forward. These included

- Financial modelling that did not fully reflect the specific project risks (e.g. construction execution, market prices, domestic demand)
- Discount rates that favored high capital projects over lower upfront cost projects
- The magnitude of the overall level of debt that both Hydro and the Province of Manitoba would ultimately be exposed to. This is especially true given the concurrent build of Bipole III, which is required for reliability purposes.

All three projects - a Bipole III, Keeyask, and the associated tie-line - should have been reviewed on an aggregate basis, instead of individually, to properly assess the collective risks of conducting all projects at once. While a Bipole III could have been pursued as a stand-alone project, the feasibility of Keeyask and the tie-line were both dependent on one another, and on construction of a Bipole III as well. Hence, separate reviews of the projects was not the best choice given their inherently interconnected nature.

[1] Manitoba Minnesota Transmission Project and the Great North Transmission Line together form the Tie Line project

Hydro took on undue execution risk by failing to fully obtain all the required approvals (notably the US Presidential and tie-line partner approvals) prior to commencement of construction of Keeyask, whose value is impacted by availability of the tie-line. Moreover, since the time the original analyses that supported proceeding with both projects was conducted, further downside risk associated with capital execution on both Bipole III and Keeyask has materialized.

Risks such as these have adversely impacted the economics of the projects and continued to put Hydro into a more and more difficult financial position, making construction of Keeyask and the tie-line in particular an even more questionable decision.

Despite our finding that the original decision by the Provincial Government and Manitoba Hydro to construct Keeyask and the tie-line was imprudent, given the current state of execution and the estimated incremental costs to cancel or delay the projects at this point, the most prudent decision – from an economic and strategic perspective – is to continue both projects to completion. However, continuing the projects will require a focus on mitigating any further downside impacts on costs and schedule to the extent they can be controlled.

Topic 1: Were the original decisions to invest the right ones to make? [Exhibit 4]

Bipole III

Manitoba Hydro's existing infrastructure of Bipole I & II and Dorsey carry significant reliability risks that have been untenable for a significant amount of time, but which should be immediately addressed upon completion of a Bipole III [Exhibit 5].
The impact of this risk is increasing [Exhibit 6] given several factors

- Approximately 70% of the Province's system's energy moves through this infrastructure
- The risks of significant incidence to these facilities are not negligible. For example, freezing rain and wind is estimated to impact Bipole I & II approximately once every 20 years, and fire risks at Dorsey are estimated to lead to reliability issues once every 29 years.
- Either of these types of events, or other significant events such as ground ice build-up or tornados, could lead to prolonged outages lasting weeks to months [Exhibit 7].
- Such events, while extremely rare, would result in an estimated $4 – 20B in negative societal impact, and hence must be planned for to avoid a catastrophic event at significant cost for multiple Hydro stakeholders [Exhibit 8].

While the decision to proceed with a Bipole III was a prudent action on the part of Hydro due to the reliability concerns of not building the asset, it should be noted that a Bipole III East route was deemed the most economic design, with funding requirements $900m[2] lower than alternatives. However, the East route option was not pursued following 2007 guidance from the Minister for Hydro to MHEB's Chair that the route would not be considered consistent with stated environmental commitments and initiatives [Exhibit 9]. The communication also stated the Corporation should

[2] As per 2007 Hydro Management West Route submission review presentation to the MHEB

move ahead with required consultations and planning for alternative routes. Of the options *ex*cluding Bipole III East, Bipole III West is the most cost effective [Exhibit 10].

Keeyask and tie-line

Unlike Bipole III, our analysis determined the accelerated commencement of construction of Keeyask with the tie-line to be an imprudent decision on the part of the provincial Government and Hydro leadership at the time of its initiation [Exhibit 4].

While new generation capacity will be needed for the region and system to ensure the ability to meet domestic load and capacity needs, this need does not consistently arise until 2027 [Exhibit 11]. Our analysis looked at the reasonability and soundness of several aspects of Manitoba Hydro's net demand and supply availability forecasts, in addition to various scenarios for Demand Side Management ("DSM") programs to identify the need for new generation [Exhibits 12, 13]. The earliest consistent need for new generation is 2027, and it is possible the need may not arise until as late as 2034 depending on actual gross demand and DSM impacts observed. This placed the originally planned 2019 Keeyask in-service date well in advance of the domestic need.

The decision to accelerate Keeyask to 2019 and build the tie-line, as opposed to building and completing construction by 2025/26 or pursuing alternative options such as gas generation, was based on an expected NPV analysis that measured the expected value versus alternatives [Exhibit 14]. Acceleration and the tie-line were of high value as they were projected to allow Hydro to meet a portion of the renewable energy needs of US customers, and hence earn attractively priced, contracted export revenues that would improve project NPV. The perception of a limited window of time to capture the benefits of the tie-line and export revenues significantly drove the decision to build on the originally planned schedule [Exhibit 15].

While this approach to offset capital costs was logical, the assumption that the window of opportunity for export to the US was closing should have been more closely scrutinized and tested. Specifically, the potential for additional future waves of renewable energy needs allowing for future export, driven not only by RPS[3], but also the US CPP[4] or other regulatory requirements, should have been more deeply assessed and considered as part of the analysis. In addition, the fact that acceleration of Keeyask led to commencement of construction prior to the tie-line receiving the required external approvals (US Presidential and the tie line partners), neither of which have been received to date, underscores the failure to perform all the important risk analyses associated with accelerating Keeyask to 2019.

Furthermore, while the expected NPV for Keeyask and the tie-line was estimated as being higher, the range of uncertainty around the expected NPV was also significantly larger than for alternatives [Exhibit 16]. This is due to larger project execution risks, industrial account electric load (i.e. demand) risks, export price and underlying hydrological risks.

[3] Renewable Portfolio Standards
[4] Clean Power Plan

Most importantly, given the financial outlook of the company (Hydro's equity ratio was expected to fall to 9% in a base case scenario) put forth during NFAT, consideration of the magnitude of project risks and their impact on the company's financial health should have been provided more weight and consideration in the evaluation [Exhibits17]. This is particularly true as Hydro already has less equity than most of its peers [Exhibit 18] and must be sufficiently capitalised to withstand the natural volatility of hydrological conditions and the impact on available energy. Further analysis of the risks related to the additional debt required to construct Keeyask and the tie-line in concurrence with a Bipole III should have also been performed prior to project initiation. In fact the level of debt being taken as part of Hydro's expansion program will dramatically increase the total level of debt taken on by and/or guaranteed by the Province [Exhibits 19].

Overall, a decision to further assess alternative options requiring less capital and lower risk profiles would have been more prudent than moving forward with Keeyask and the tie-line at the time the decision was made.

To the credit of Hydro, several aspects of the planning and decision process were conducted well. For example, the construction of Keeyask is an extremely complicated endeavor from technical, operational, and commercial perspectives. That the project was successfully designed and agreed to by multiple parties, stakeholders, and contract holders is a significant achievement that should not be overlooked in assessment of the project. Moreover, the fact that multiple highly favorable US export term contracts were negotiated prior to initiation demonstrates the attempts by project leadership to mitigate at least a portion of the financial and export risk associated with the project [Exhibit 20]. Further, Hydro conducted several analyses regarding potential risks to the project, including low water flows and changes to gas and CO_2 prices [Exhibit 21]. Although the ultimate acceptance of some of the risks identified is questionable, in particular with relation to acceptance of low equity ratios in future years, it is clear Hydro and the Province attempted to weigh several important risks related to the project.

Underlying Factors to Address

To help avoid similar situations in the future, our analysis has sought to trace back the underlying factors leading to the decisions to proceed with Keeyask and the tie-line. The decision can be traced back to systemic decision governance issues that must be addressed by Hydro and the Province of Manitoba. More specifically:

The Province, Hydro and the Regulator lack clear objective functions and criteria / constraints

- For example, it is unclear if the primary role of Hydro, on behalf of the Province (its owner), is to drive economic growth or serve domestic energy needs, which at times may come into conflict as a result of normal operations. In times of adverse operating conditions or capital expansion, this may leave the business with an insufficient or high risk equity base.
- With respect to the Regulator, there is a clear track record of favouring low rates, in accordance with AURAA[5], but less clear is the role they play in balancing responsible asset

[5] Affordable Utility Rate Accountability Act

stewardship by Hydro and setting reasonable reliability targets to manage both costs and system performance [Exhibit 22]. Clarification of the objective functions, specific criteria, and constraints on such criteria for both Manitoba Hydro and the Regulator would be of great importance in helping build transparency for planning and operation of the system.

Current rate-setting mechanisms do not link rates to an allowable return, disconnecting revenue recovery from the system investment plan [Exhibit 23].

- This in turn drives increased financial uncertainty at Hydro, which results in more precarious financial conditions (e.g., acceptance of a projected equity ratio that reaches as low as 9% in the near future).
- A revenue model more directly linked with Manitoba Hydro's cost to serve, the maintenance of its financial health, and its future investment needs to serve customers would be an important change in regulation that would more appropriately adjust to the ever changing needs of the system in order to provide reliable electric service.

The current project planning approach is iterative, instead of being consolidated in an upfront manner [Exhibit 24].

- This limits insight into the compounded execution and financial risks from running several major, simultaneous projects concurrently, even when they have clear interdependencies as is the case with Bipole III, Keeyask and the tie-line
- A more consolidated planning approach with respect to major projects – one that takes into account the combined opportunities and risks for the company and its stakeholders – would be more appropriate to implement.

Topic 2: Is there further downside risk to the projects? [Exhibit 25]

Our analysis identified six key factors that have a significant impact on overall economics of the projects and financial health of the business. Each of these was reviewed regarding the assumptions used, to define the probability of further downside risk to the projects. [Exhibit 26].

- **Water flows:** Remains the largest variable, for both the Keeyask and the existing generation assets. No change in the underlying risk range
- **Capital execution** The capital execution costs have already shifted in an unfavorable direction for Hydro
- **Export prices**: Expected opportunity sales (i.e. those sales exclusive of the favorably priced contracted volumes) have already trended toward the low end of MISO sales price range
- **Interest rates**: Short and long term rate expectations have moved favorably since the original assessment of the projects
- **Domestic electricity rates:** While still within the original risk range, the Provincial Utility Board (PUB) granted only a 3.36% domestic rate increase for one year vs. the requested 3.95% for multiple years in Manitoba Hydro's last filing, reducing revenue versus the baseline.

  Net domestic demand: There is no further change in the expected range of domestic demand

Despite the favourable movement in interest rates the adverse movements in capital execution versus the expected schedule and in export prices in MISO have negatively impacted the project economics.

With respect to capital execution, if mitigation initiatives are implemented to limit further slippage to cost and schedule, ~$1.0B in additional capital[6] [Exhibit 27] is expected to be required due to an expected 12 month delay in Bipole III [Exhibit 28], and 21 month delay in Keeyask [Exhibit 29]. Should the mitigation initiatives either not be implemented or prove to be less effective than expected, schedules could further slip by an additional 3 months for Bipole III and 11 months for Keeyask, requiring an additional ~$0.7B in capital [Exhibits 30, 31].

Regarding export prices, while contracted prices remain unchanged (at favourable levels), the 2016 "reference" scenario now includes opportunity sales at export price forecasts that are below the prior IFF '15 estimates (13-17%). For the non-contracted portion of export revenues, these adjustments will shift the risk range of the project NPV down [Exhibit 32].

Some of the risks above have materialized and impacted Manitoba Hydro's financial metrics [Exhibit 33]. The ultimate impacts could be even worse should additional downside risks – both controllable and uncontrollable by Manitoba Hydro – be experienced [Exhibit 34].

Topic 3: Can the projects be stopped or paused without undue cost or risk? [Exhibit 35]

Despite the finding that the Keeyask project was undertaken without sufficient review and consideration of the risks – some of which have materialized leading to cost overruns and lower revenue expectations upon project completion –on a 'go-forward' basis continuing the projects remains the lowest risk, lowest cost, highest value option.

An added consideration is the interdependent nature of the projects. Transmitting and exporting power from Keeyask will depend on the new transmission capacity provided by Bipole III and the tie-line. Cancelling the current Bipole III project would effectively strand much of the capacity of Keeyask and make it financially implausible that the project could be continued in its current form.

If the projects were stopped today, it is estimated that, in addition to the costs already incurred (~$5B across the projects), an additional ~$1B would be incurred for each of Bipole III and Keeyask, bringing the total project costs to ~$7B [Exhibit 36].

Stopping the projects would also result in no functioning assets being available to the system for the amount spent, continued significant and real reliability risks associated with Bipole I & II and the Dorsey station, the requirement to procure additional generation to meet Manitoba Hydro's load in the coming years (e.g., by 2027), and other undesired impacts to Manitoba stakeholders [Exhibit 37].

[6] Includes interest and escalation costs

Cancelling Keeyask would require near immediate commencement to build alternative generation options to avoid the risk of Hydro being unable to meet its domestic reserve capacity needs by 2027 when current generation capacity may prove insufficient[7].

Completing the projects is still expected to yield a net present value more favourable than rerouting to Bipole III East or switching to gas generation, by an estimated ~$4 - $6B [Exhibits 38,39].

Final Conclusions and Recommendations

Based on our analysis we believe building a Bipole III line was a reasonable undertaking for reliability purposes, despite the fact that the most cost-effective design to the East was not pursued. However, construction of Keeyask was an imprudent project to undertake in parallel without further consideration of the risks and impacts of concurrently executing the projects with a Bipole III. Some of these risks have begun to materialize, in particular those related to capital execution, creating further strain on the projects and underscoring the original need for enhanced review and analysis before the projects began construction. Notwithstanding these findings, it is our recommendation the projects continue, as, given the estimated costs to complete, the non-economic impacts, and the expected NPV versus alternatives at this point, continuation remains the best path forward for Hydro, the Province, and their stakeholders.

[7] In addition cancellation of Keeyask would cause Hydro to be unable to fulfill its existing interim contracted volumes, which are at favorable pricing. And it could make Hydro a less credible counterparty for longer term contracts in the future

Tab 23

SUBJECT: Contingency

REFERENCE: NFAT Technical Conference 09-06-2013 transcripts page 441 line 15, Manitoba Hydro has stated: "And it's Manitoba Hydro, our corporate policy, to use the P50 estimate in the contingency development."

PREAMBLE: While a corporate contingency guideline of 50 percent probability of overrun for projects that are part a total annual capital budget may be fine in incidences where numerous smaller capital projects make up a total annual budget and where cost variations on one project may be offset by that of another project, this may not be the case for large projects.

In an article, entitled "Monte Carlo Analysis: Ten Years of Experience" from Cost Engineering (a publication of the American Association of Cost Engineers) Vol 43/No. 6 June 2001 states: "The 50 percent probability guideline is not applied to very large projects or to strategic projects outside the annual capital budget. For these, the 10 percent to 20 percent probability of overrun is often acceptable. When applying MCA (Monte Carlo Analysis) to projects at a very preliminary stage, management usually requires a very low probability of overrun, possibly 5 percent."

QUESTION:

Please provide the probability distribution curve used to determine the P50 or alternatively please provide the P80, P90, and P95 values and associated contingencies.

RESPONSE:

Keeyask contingency amounts associated with requested P-values are as follows:

P-Value	Contingency Amount
P50	$527 million
P80	$848 million
P90	$950 million
P95	$1032 million

59	Manitoba Hydro to provide confirmation that the road costs that are attributable to Conawapa are not included in the $380 million that Manitoba Hydro wants to amortize over the thirty (30) years	5837

--- Upon commencing at 9:29 a.m.

RULING:

THE CHAIRPERSON: Morning, everyone. I apologize for the technical delay. Before we start today, the Board is going to issue a ruling in relation to Manitoba Hydro's request to give rebuttal evidence in response to Morrison Park Advisors.

In this proceeding, Intervenor expert witnesses and the independent expert consultants retained by the Board provided written prefiled evidence in the form of expert reports. Manitoba Hydro was given the opportunity to file written rebuttal evidence in response to the expert reports filed by Intervenor witnesses and the independent expert consultants and did so in response to the reports of the Intervenor expert witness -- witnesses; the Daymark expert -- export - independent expert consultants; the Daymark load - independent expert consultants; Dr. Adonis Yatchew; and MGF Project Services.

After providing written prefiled evidence, a number of the Intervenor expert witnesses and the independent expert consultants have given oral evidence in this proceeding. There are also still

Intervenor expert witnesses in independent expert Consultants scheduled to give oral evidence in the remaining two (2) weeks of the evidentiary portion of this hearing.

Morrison Park Advisors is an expert witness in this proceeding, and was jointly retained by the Consumers Coalition and the Manitoba Industrial Power Users Group. Morrison Park Advisors filed written prefiled evidence in accordance with the deadlines set by the Board. All parties had the opportunity to ask written Information Requests of Morrison Park Advisors, following which Manitoba Hydro responded to the written prefiled evidence in its written rebuttal.

Mr. Pelino Colaiacovo gave oral direct expert evidence in the oral evidentiary hearing on -- of this General Rate Application on January 15, 2018.

On January 16, 2018 during Manitoba Hydro's cross-examination of Mr. Colaiacovo, Manitoba Hydro reserved the right to call rebuttal evidence to respond to what was, in its position, new evidence raised in his oral testimony. This is found at page 5111 of the transcript and was further explained by Manitoba Hydro beginning at page 5140 of the transcript.

The testimony in question related to slides 17 and 18, of Mr. Colaiacovo's oral presentation marked as Consumers Coalition Exhibit 45. The testimony in question also related to a spreadsheet provided by him with his PowerPoint slide presentation, which was marked as Consumers Coalition Exhibit 46.

In cross-examination by Manitoba Hydro, Mr. Colaiacovo confirmed that the analysis on slides 17 and 18 of Consumers Coalition Number 45 and the spreadsheet marked as Consumers Coalition Number 46 was not included in his written prefiled evidence.

Manitoba Hydro's position is that as the calculations presented by Mr. Colaiacovo were not presented in his initial evidence, the Utility should therefore have the right to respond to the new analysis.

This request was not opposed by the Consumers Coalition or the Manitoba Industrial Power Users Group. As set out in the leading Sopinka, Lederman & Bryant text, The Law of Evidence in Canada, the right to call rebuttal or reply evidence is limited to new issues raised in the evidence and does not include matters which might properly be considered to form part of the Applicant's case in-chief.

Rebuttal evidence cannot be used under the guise of replying to confirm or reinforce the case which the Applicant was required to make out in the first instance. This ensures fairness for all those who are engaged in testing the Applicant's case.

The Board has determined that the analysis presented by Mr. Colaiacovo on slides 17 and 18 of his direct presentation and supported by the spreadsheet marked as Consumers Coalition 46 is new evidence, not previously raised in the written prefiled evidence of Morrison Park Advisors or responses to Information Requests. As such, it could not reasonably have been anticipated by Manitoba Hydro.

Manitoba Hydro can, therefore, properly address this evidence through calling rebuttal evidence on February 2nd, 2018, the day currently reserved in the schedule for that purpose. Should Manitoba Hydro's rebuttal evidence include new analysis or calculations performed by the Utility, such analysis or calculations must be provided to all parties by no later than 5:00 p.m. on January 31st, 2018. All parties will be given an opportunity to ask questions of the Manitoba Hydro witnesses called to give oral rebuttal evidence.

Based on the submissions of Manitoba Hydro, the Board has furthered determined that to date this matter is the only matter in this proceeding that is properly the subject of oral rebuttal evidence, unless another new matter is raised in the remaining scheduled oral testimony of Intervenor and independent expert consultant witnesses.

Manitoba Hydro's oral rebuttal evidence will be strictly limited to addressing only the evidence that formed the subject of this request as set out in page 5111 of the transcript.

This opportunity for the Utility to call oral rebuttal evidence cannot be used to attempt to reconfirm or reinforce its case in-chief, including any matters that could have reasonably been anticipated by the Utility. Should any further new evidence be raised in the oral testimony of the remaining scheduled witnesses that Manitoba Hydro wishes to respond to oral rebuttal evidence, Manitoba Hydro should make the appropriate request of the Board. Thank you.

Mr. Simonsen, if you could swear in the witnesses, please.

MANITOBA HYDRO PANEL 4 - MAJOR CAPITAL PROJECTS

JEFF STRONGMAN, Sworn
DAVID BOWEN, Sworn
LORNE MIDFORD, Sworn
DAVID CORMIE, Sworn
ALISTAIR FOGG, Sworn
GLENN PENNER, Sworn

THE CHAIRPERSON: Ms. Van Iderstine...?

MS. HELGA VAN IDERSTINE: Thank you, Mr. Chair. I would like to just enter before we start two (2) exhibits, the Capital Panel CVs should be entered as Manitoba Hydro Exhibit Number 118. And the presentation which you're about to hear should be entered as Manitoba Hydro 120.

MR. KURT SIMONSEN: Thank you.

--- EXHIBIT NO. MH-118: Capital Panel's CVs

--- EXHIBIT NO. MH-120: Capital Panel's PowerPoint presentation.

EXAMINATION-IN-CHIEF BY MS. HELGA VAN IDERSTINE:

MS. HELGA VAN IDERSTINE: Thank you. And with that, I'd like to introduce Mr. Lorne

Midford, who is going to lead the presentation.

THE CHAIRPERSON: Sorry, for a second. Mr. Simonsen, we have it written down as 130, is it --

MR. KURT SIMONSEN: 120.

THE CHAIRPERSON: It's 120, okay, thank you. Sorry, Ms. Van Iderstine.

MS. HELGA VAN IDERSTINE: So with --

MR. KURT SIMONSEN: Sorry, just to backup, 119 is -- is a letter from Manitoba Hydro to PUB regarding the MGF redacted report.

(BRIEF PAUSE)

--- EXHIBIT NO. MH-119: Letter from Manitoba Hydro to PUB regarding the MGF redacted report.

THE CHAIRPERSON: Sorry, Ms. Van Iderstine...?

CONTINUED BY MS. HELGA VAN IDERSTINE:

MS. HELGA VAN IDERSTINE: And with that, I'd like to introduce Mr. Lorne Midford who is going to lead the Keeyask portion of -- or who's going to lead the capital panel.

I would just caution you and let you know that as you saw when they're being introduced, we've got almost everybody up here. We have one (1) person who's in the back, so, they're going to move back and forward during the -- the presentation so that the appropriate person's in the front row.

And the other thing, just to let you know, is that we anticipate the Keeyask present -- portion of the presentation, which is the starting portion, will take up the majority of the time up until what you've got your scheduled breaks. So, we'll ask whether or not you want to proceed with a break at that point.

THE CHAIRPERSON: Thank you.

MR. LORNE MIDFORD: Good morning, Mr. Chairman, Madam Vice Chair, Board members, Board advisors, Intervenors, and our audience. I'm Lorne Midford and I am the vice-president of Generation and Wholesale at Manitoba Hydro. And since early 2016 I have executive responsibility for construction of the Keeyask generating station. And I also chair the Keeyask Hydropower Limited Partnership Board of Directors. It's a pleasure to be here.

Before I introduce our panel members, I'd just like to take a minute to pass on our condolences to the family of Todd Maytwayashing, who tragically lost his life last week following a workplace accident at a marshaling yard near the Limestone generating station on the lower Nelson River. Our thoughts and prayers go out to his family.

Beside me is David Cormie who I don't think needs any introduction. He's -- you're already familiar with Mr. Cormie. He's a part of the panel today through his involvement with both the Great Northern Transmission line and the Saskatchewan transmission line.

Glenn Penner behind us is the Director of Transmission Construction and Line Maintenance. Glenn is responsible for a diverse team of project managers, designers, engineers and lifeline workers. He has been with Manitoba Hydro for almost twenty-seven (27) years, much of that in transmission working in a variety of roles throughout including structural engineer and manager of transmission construction.

Beside David is Alistair Fogg. Mr. Fogg is the manager of the Converter Commercial and Controls Department in the Bipole III Converter Stations Division. Alistair is a professional engineer with a Masters of Business Administration and has a CMA designation. Alistair manages project control functions for the Bipole III project, including commercial support, contract strategies, project cost and schedule, change management and risk management.

Beside me is Dave Bowen. Mr. Bowen is the Director of the Keeyask project. Dave has over twenty (20) years of experience in both the consulting engineering and electric utility business. He's a registered professional engineer and has a Master of Science in Engineering. Dave's work experience has seen him taking on progressively senior roles as an engineering consultant in areas of infrastructure and within Manitoba Hydro, focused on the delivery of new generation projects. This has included work on the Wuskwatim generating station, Pointe du Bois spillway, Bipole III and Keeyask projects.

And beside David is Jeff Strongman. Jeff is the manager of the Keeyask Business Department. He's a civil engineer with over twenty (20) years of experience in the consulting, manufacturing and construction industries and prior to working on the Keeyask project, Jeff was a senior contracts negotiator working primarily on development of agreements with Minnesota Power on power export sales and a new transmission interconnection to the

United States. Prior to that, Jeff played a key role on the construction team during the Wuskwatim generating station build.

For myself, I am a professional engineer with thirty-two (32) years of experience in the electric utility business; about half in the transmission side of the business and half in the generating station side of the business.

So now I'd like to start the presentation. We're on slide 2. Nearly all of the electricity we produce each year is clean, renewable power generated at 15 hydroelectric generating stations on the Nelson, the Winnipeg, Saskatchewan, Burntwood, and Laurie Rivers.

We also operate two (2) thermal generating stations at Brandon and Selkirk which are, essentially, only used for backup power and four (4) small remote diesel generating stations at the off-grid communities of Brochet, Lac Brochet, Shamattawa and Tadoule Lake.

Our total generating capability is just under 5700 megawatts and Keeyask, once complete, will increase this capacity to just under 6400 megawatts. We also have wind power purchase agreements from independent windfarms at St. Leon and St. Joseph.

Manitoba Hydro's transmission system transmits electricity from generating stations around the province and also interconnects the Manitoba system with neighbouring provinces and states. Our major high-voltage transmission lines operate at 115,000 volts to 500,000. The high-voltage MR. DAVID CORMIE: lines shown in this picture are, essentially, an expressway for the majority of power that is generated in the north and transmitted to the south. The power that is generated in the north system is converted to high-voltage direct current at two (2) converter stations Radisson and Henday and transmitted over 1800 kilometres to Dorsey converter station just outside Winnipeg where it's converted back from high-voltage direct current to high-voltage alternating current.

We deliver electricity to our customers using over 18,000 kilometres of transmission lines and 68,000 kilometres of distribution lines.

Slide 3. Keeyask generating station is a collaborative effort between Manitoba Hydro and four (4) Manitoba First Nations working together as the Keeyask Hydropower Limited partnership. Our four (4) Cree nation partners are: Tataskweyak Cree Nation and War Lake First Nation acting as the Cree nation partners; York Factory First Nation and Fox Lake Cree Nation. The partnership is governed by the joint Keeyask Development Agreement, sometimes referred to as the JKDA, which outlines such things as the contractual investment terms for the partnership and outlines commitments in the form of training, employment and business opportunities during construction, as well as the ongoing governance structure.

Slide 4. The Keeyask Hydropower Limited Partnership has a Board of Directors with representation from all four (4) partners. The Board meets at least quarterly to review the project status, review any issues and concerns and, essentially, provides an ongoing and regular opportunity to meet and to talk and to provide feedback for the project.

I can tell you at a very personal level that I've come to better understand the Cree worldview. I've come to better understand the impact our legacy operations have had on these communities. And I've come to better understand the importance of reconciliation. And I continue to learn and to understand and I thank our Cree Nation partners for putting their confidence in me as chair of the Keeyask Hydropower Limited Partnership. Keeyask, and our approach to planning, constructing and operating this station like Wuskwatim is to Tataskweyak before it, is a cornerstone for Manitoba Hydro on behalf of the province to build a long-standing positive relationship with our Cree Nation partners based on respect and trust.

To reconcile the past, to work together for a better future, this will take some time. Reconciliation is a long journey. If the Tataskweyak is any indication, I'm very confident that we're on the right path and with time and openness, we will get there together.

I don't want to take too much time but this is so important to me personally and to the -- everyone involved in the project that I'd like to share a story with the Board, perhaps to provide some perspective.

In 2015 when the rock was being excavated for the powerhouse, essentially 100 foot rockface was drilled and blasted out of the rock, which is where the units will ultimately generate their power. In this rockface, there was a relief of a face in the rock that appeared that was perhaps ten (10) to fifteen (15) feet high. When I first learned of this by a photo that was circulating, I thought it was interesting, and frankly quite cool. But I can tell you that I didn't give it any more thought than that nor did others who did not grow up as the Cree have. Our Cree partners, on the other hand, had a very, very deep spiritual connection with this event and because of my and other's lack of acknowledgment and understanding, it created conflict and sadness with our Cree partners; that, of course, was unintentional.

We had emergency meetings with the Keeyask Hydropower Limited Partnership Board and through a lot of discussion and learning, we hosted several ceremonies both at site and within some of the communities to recognize the significance of this event. These ceremonies that I participated in were very moving. I can tell you that this is just one (1) example of how we are learning and continue to learn and to understand as we travel on this long journey of reconciliation.

The Keeyask Hydropower Limited Partnership Board also commissioned paintings from two (2) of the Cree nation communities to commemorate the rockface from Fox Lake Cree Nation and Tataskweyak Cree Nation which you can see on the -- on the screen in front of you. These lovely paintings hang on the wall at the check-in desk at the Keeyask camp and will, ultimately, find a home at the Keeyask generating station when it is complete. So when you visit the Keeyask site and you see these pictures hanging on the wall when you check-in, I hope you may reflect on this story. And understand that several Board members have had the opportunity to travel to Keeyask and look forward to future opportunities to host members of the Board as well at the site.

Slide 5. The Keeyask Hydropower Limited Partnership will own the Keeyask generating station. The Keeyask Hydropower Limited Partnership is structured as a limited liability partnership consisting of a general partner with .1 percent, a wholly owned subsidiary of Manitoba Hydro and four (4) limited partners with 99.9 percent. Manitoba Hydro, the Cree Nation partners made up of Tataskweyak and War Lake, Fox Lake Cree Nation Limited partnership and York Factory First Nation Limited Partnership.

The general partner manages the affairs of the Keeyask Hydropower Limited Partnership and has contracted with Manitoba Hydro to construct and operate the project. The general partner is managed by a Board of Directors consisting of seven (7) Manitoba Hydro reps and five (5) Keeyask Cree Nation reps, a monitoring advisory committee and a construction advisory committee provide advice to the Board. An advisory group on employment provides advice to the Manitoba Hydro project manager and also provides reports to the board. And an issues coordination committee, in turn, triages issues for discussion and direction to the Board of Directors.

Mr. Bowen is the director of the Keeyask project, and he reports directly to me. Dave has structured his team into areas of site construction manager, commercial contracts manager, engineering manager, and business manager.

The major projects -- slide 6. The major projects executive committee, which is Chaired by our President and CEO Kelvin Shepherd, oversees, directs, and makes strategic decisions on Manitoba Hydro's major capital projects. The executive committee was established in early 2016, with membership from the president and CEO, vice president of transmission, vice president, myself, generation and wholesale, vice president of HR and corporate services, vice president of Indigenous relations, and vice president of finance and strategy. The executive committee meets biweekly, or as often as required. Each operating group retains authority and accountability of the project within their scope of accountability.

I would now like to pass it over to Mr. Strongman.

MR. JEFF STRONGMAN: Thank you, Lorne.

(BRIEF PAUSE)

MR. JEFF STRONGMAN: Manitoba Hydro's Keeyask team is comprised of roughly two hundred and twenty (220) people split geographically between the Keeyask site and the corporate head office in Winnipeg. The site team, headed by the construction manager, is located at Keeyask and provides construction oversight and project management. The engineering, contracts management, and business teams are stationed in Winnipeg, as well as other corporate resources to provide the necessary support to the construction team at site.

Slide 8. So what are we building? We're building two (2) things. First, the 695 megawatt Keeyask Generating Station will be the fourth-largest generating station in the Province, providing 12 percent of Manitoba's renewable energy. It's clean, renewable energy that will benefit

Manitobans for more than one hundred (100) years. Secondly, we're building a stronger relationship with our First Nation partners.

The Keeyask project...

(BRIEF PAUSE)

MR. JEFF STRONGMAN: How's that? Is that better? Okay.

The Keeyask project includes a seven (7) unit powerhouse, a seven (7) bay spillway, an extensive network of dams and dikes, all-supporting infrastructure, which includes camp, access roads, and temporary infrastructure such as cofferdams, and all required transmission facilities. The Keeyask site is located on the Nelson River in northern Manitoba, roughly 700 kilometres north of Winnipeg, and 180 kilometres northeast of Thompson.

I understand that some of the members attended the site. I'll just give you a -- a rough roadmap of the road that you took once you landed in Gillam. Starting in Gillam, you'd proceeded east on the highway, away from the project site, in order to cross the Nelson River at the Limestone Generating Station, then back west towards the Keeyask site on

PR290. Then you turn left on the Keeyask access road, pass through the security gate, and finally arrived at the main camp after roughly two (2) hours.

Also note on this map the location of our partner communities and their close proximity to the site, Bird and Gillam on the right side are Fox Lake communities. On the left, Split Lake is the Tataskweyak First Nation community, York Landing is the York Factory First Nation community, and Ilford is the War Lake First Nation community shown.

(BRIEF PAUSE)

MR. JEFF STRONGMAN: This aerial photo, you can see the project site before construction. The Nelson River flows from the left to the right in this photo, and is roughly 1000 metres wide as the river approaches the Gull Rapids. At that point, the river splits into three (3) channels, referred to the North, Central and South channel, with the North at the top. Through the rapids, the river drops 12 metres in elevation, which makes it an attractive site for the placement of a generating station.

Slide 10. This rendering shows the

layout of the principal structures at Keeyask with, again, the flow from the left to the right, and the top being North. The powerhouse is located on the north side of the river, and is a -- a mile from the spillway, separated by the Central dam. There will be short dams on the North and South side as well. Keeyask is constructed in relatively flat terrain, so it requires extensive diking, roughly 23 kilometres total.

The principal structures of the Keeyask Generating Station are the North and South dikes along the upstream shorelines, the North dam that connects the North dike to the powerhouse, the powerhouse complex constructed on the North side of the river, including an intake and tail race channel, a Central dam that will connect the powerhouse to the spillway, a spillway structure located on the North side of the Gull Rapids South channel, including the intake and -- and tail race channels, and the South dam that connects the spillway to the South dike.

Slide 11. This is an artist's rendering of the Keeyask powerhouse, once finished. In order to provide context on the size, the height to the top of the powerhouse is equivalent to -- pardon me. The height to the top of the Manitoba Hydro building is 88.6 metres, and the height of the powerhouse is 64 metres, which is roughly three quarters (3/4) of the height of the Hydro building. The powerhouse is 64 metres by 64 metres by 192 metres long. The total length is over two and a half (2 1/2) football fields.

(BRIEF PAUSE)

MR. JEFF STRONGMAN: The second of the two (2) principal concrete structures is the spillway. And slide 13 is an artist's rendering of the Keeyask spillway, showing the completed version. Again, for context, comparing the spillway to the Manitoba Hydro building, the spillway is tall as the 17th floor of Manitoba Hydro. The spillway's dimensions are 60 metres high, 44 metres wide, and 119 metres long.

MR. JEFF STRONGMAN: Slide 15. The river management structures are the main features of this slide, and they are highlighted in green. In order to perform the construction work, the natural path of the North and Central channels of the river have been blocked by cofferdams, forcing the river to pass the construction site through the South channel. Inside these cofferdams, all the water has been pumped out so that the work can progress in dry conditions.

Slide 16 is a typical cross-section of a dam. The schematic depicts a typical permanent earthwork structure, such as what we were building in the North, Central and South dams. Shown are the impervious core and successive layers of rock designed for sufficient strength to hold back the pressure of the water on the west side of the dam. Not shown on this schematic is the variability of the underlying bedrock upon which the structure is built.

The top left picture in slide 17 is a -- a photo depicting the cleaning of the bedrock surface to what's referred to as dinner plate clean. The bottom left is the placement of dental concrete as a means of leveling the bedrock, and on the right, a portion of the central dam under construction in the summer of 2017.

Slide 18 shows the permanent structures of Keeyask overlaid on a map of Winnipeg. Again, this is designed to try to achieve context and perspective of the extent of the site. The South dike is 10 kilometres long, 22 metres high, roughly 10 metres wide at the top. The North dike is 11.6 kilometres long, 17 metres high, and roughly 10 metres wide at the crest. The North Dam is 320 metres long, 24 metres high, and 10 to 15 metres wide at the crest. The Central dam is 1,577 metres long, 28 metres high, and 15 metres wide at the top. And the South dam is 610 metres long, 22 metres high, and 15 metres wide at the top.

When you overlay the permanent structures on a map of Winnipeg and extend from -- there's -- they extend from Portage and Main almost to the west perimeter. Note that the North dike extends out of downtown, past Polo Park, continues to the James Richardson Airport, well into St. James, and the South dike extends out of downtown, through the Osborne junction, then west through River Heights, and into Charleswood, past Assiniboine Park, ending south of Wilkes.

Slide 20. We've taken the concrete structure of the powerhouse and overlaid it into a block of downtown. Similarly, the service Bay would take up a -- a similar footprint. The infrastructure required to support Keeyask include the following -- this is slide 21 -- 23 kilometre north access road, linking the Keeyask site to PR280, a 25 kilometre south access road linking the site to Gillam, a major bridge structure over the Looking Back Creek, and a two hundred (200) person start-up camp, and a twenty-four hundred (2,400) person main camp at either ends of the access road.

Slide 22 is the Keeyask transmission project, which has two (2) main components. The first is providing the power required for the current -- the construction of the Keeyask Generating Station, and the second is to transmit the power from Keeyask to the Manitoba Hydro Converter Stations linking and integrating the station into the Manitoba Hydro system. The Keeyask transmission project includes the construction of a power line and station, a switching station on the south side of the Nelson River, three (3) generation outlet transmission lines, four (4) unit transmission lines, and upgrades to the Radisson switching station.

Manitoba Hydro has incorporated lessons learned from previous projects, including Wuskwatim, at a cost of 1.4 billion, at Pointe du Bois, at a cost of 0.6 billion, into the delivery of Keeyask. The Corporation's project management capabilities have been built up over the last ten (10) years in preparation for delivering Keeyask and the Bipole project.

Lessons learned from past projects include: Early contractor involvement is valuable.

The contract model has to fit the circumstances and market conditions. Goals and incentives must be mutual and tied to project critical success factors. Independent third-party reviews are beneficial, providing independent perspective on the projects and processes enhances the opportunity for continuous improvement. Rigorous oversight is essential. Project integration is critical to success. Manitoba Hydro has to be active in managing the interface points between contracted work packages, and doing things as they have always been done does not work for complex projects that require constant innovation and a culture of collaboration.

Slide 24. Keeyask is a complex, multiyear Hydro construction project with suffic -- significant coordination and integration requirements. It's being developed at a remote Northern location with access from only one (1) Provincial highway that's -- and that's Provincial Road 280. Productivity of trades has been declining over the last twenty (20) and thirty (30) years.

On-site camp is required capable of accommodating the peak workforce of twenty-four hundred (2,400) workers. Seasonal constraints exist, and they limit the warm weather construction season significantly. Operating in a regulatory environment that includes necessary constraints such as environmental spawning windows that limit when certain construction activities occur.

River management is key. The Nelson River is over a kilometre wide, requiring significant earth structures for the variable flow conditions. Large earthworks projects with subsurface conditions within the former river channel can significantly impact the design and the construction of the project.

Slide 25, employment. Employment on the Keeyask project is a real success story, as the vast majority, 73 percent to date, of Keeyask workers are from Manitoba. As well, our project has enjoyed unprecedented employment from our partner communities, the First Nations within Manitoba. Midway through 2017, the project reached a significant milestone of 2 million person hours worked by our Keeyask partners and 4 million person hours worked by Indigenous people.

(BRIEF PAUSE)

MR. LORNE MIDFORD: In addition to the vast majority of project employees coming from

Manitoba, our project workers come from across the provinces of Canada and roughly half of the United States. In addition, project workers also come from Portugal, Italy, the United Kingdom, Australia, Chile, and Argentina.

Slide 27. A project site the size of Keeyask draws on global resources to fulfil its -- all of its requirements. Manitoba supplies the generator step-up transformers and trashracks. From across Canada the intake and spillway gates are supplied, as well as the powerhouse crane, intake, and draft tube cranes, turbine components, and the governors. From the United States we source the isolated phase bus and the exciter. And from Europe and Brazil we source the turbines, generators, and generator circuit breakers.

(BRIEF PAUSE)

MR. LORNE MIDFORD: Slide 28. The Keeyask project has a strong safety record for a large complex project in a remote location. However, last week a tragic accident took place. An employee of a contractor working for Manitoba Hydro near the community of Gillam suffered a fatal injury on January 17th, while securing tower steel bundles to a flat deck semi. The worker was an employee of Forbes Brothers, tasked with building the transmission line that will carry power from Keeyask to the Radisson converter station just out -- just outside of Gillam. Our hearts go out to the family. We cannot comment further until the investigation is complete.

To date, over 15 million person hours have been worked on the project to the end of 2017. The project is performing well compared to the construction sector in Manitoba. The lost time incidence rate for the project to date is less than one-tenth (1/10) of the provincial rate. The Keeyask project rate is zero-point-two-nine (0.29) lost time incidents compared to the construction sector average of four-point-two (4.2). The general civil contractor has gone over one (1) year without a lost time incident. Manitoba Hydro and all of our contractors will continue to work on our goal of zero injuries.

(BRIEF PAUSE)

MR. LORNE MIDFORD: Slide 29. The contracting model is specifically tailored for each contract and scope of work. This includes an evaluation of the market capacity, potential competition, constraints, and capabilities within Manitoba Hydro. This also involves allocating risk to the party who is best able to manage it.

There are variety of types of contracts. The four (4) main ones that are used on this project include cost reimbursable, where the contractor is paid for all of its allowable expenses plus a -- plus an additional payment for profit. The second is a target price, which is based on a cost reimbursable mechanism in which the contractor is reimbursed for actual costs subject to the application of a pain/gain formula at the end of the project based on performance.

A fixed-price contract is where a contractor is paid a predetermined price to complete the work regardless of actual costs. And the fourth type is a unit price contract where the contractor is paid a fixed sum for each unit of work complete.

Slide 31 shows the major contract types. This is a list of the Keeyask contracts whose value exceed 35 million. Note that there are total of two hundred and thirty-nine (239) contracts awarded to date, and that only the largest eleven (11) on the con -- on the project are shown on this slide.

Earlier when I spoke of the types of

contracts, you can see in the column on the right how all fit -- all four (4) main types are utilized in this project. For example, the turbines and generator contract to supply and install seven (7) units is a fixed-price because the scope of work is very clearly defined, while the service contracts, such as camp operations, are cost reimbursable largely because they are a function of time. The service contracts continue in duration for however long the construction phase requires to completion.

Slide 32, some remarks about the general civil contract. The general civil contract, or GCC as it's commonly referred, was awarded to BBE Hydro Constructors Limited Partnership in March of 2014. BBE is a tri-party consortium including Bechtel Canada, Barnard Construction of Canada, and EllisDon Civil Limited. It is by far the largest contract on the project, and includes the following key scopes of work: coffer dams, which are temporary river management structures; rock excavation; principal concrete structures, including the powerhouse and spillway; the earthwork structures, including the dams and dikes; and the electrical and mechanical work.

This contract was awarded as a single contract rather than a separate contract for the electrical and mechanical work, which was done on Wuskwatim, to minimize the interface risks and delays in coordinating other parties to take over the work from the general civil contractor as the concrete work progresses. This is subject to significant variability based on performance rates to completion.

Slide 33. In order to understand the context surrounding the decision to proceed with the general civil contract as a target price contract, we need to rewind the clock back five (5) years to 2012 when the procurement process was underway. At that time oil prices exceeded a hundred dollars per barrel and the North American megaproject market was hot, with dozens of capital expansion projects taking place in northern Alberta as well as LNG projects across the country.

In that environment megaproject contractors were not accepting hard money contracts where many risks such as labour productivity pass on to contractors without substantial and cost prohibitive premiums. This caused owners to proceed with alternative forms of contract sharing risk, where possible, and retaining them where they couldn't be passed on.

On the Wuskwatim project, Manitoba

Hydro attempted to tender the general civil contract as a unit price contract. However, the market was hot and unresponsive to hard money contract. As a result, Manitoba Hydro received only one (1) bid, which was cost prohibitive. Another lengthy procurement was undertaken, culminating in a responsive, competitive process and an award of a target priced cost reimbursable contract to O&E who performed the general civil contract work for Wuskwatim.

Slide 34. This is a timeline of the general civil procurement process. The procurement of the Keeyask general civil contract required a three (3) step process. The first step was market sounding to identify and open communications with potential parties interested in and capable of doing the work. This took place in early 2012.

The second step is the preq -- prequalification phase, where the market is invited to indicate interest in becoming prequalified to bid on the work. This took place in the second half of 2012. Seven (7) parties responded to Manitoba Hydro's invitation and four (4) proponents were qualified in early 2013.

The third and final step is the call for proposals from the four (4) qualified -- qualified proponents, which was done in the second half of 2013. All four (4) proponents responded to the call and submitted proposals. The submissions were evaluated on best value to Manitoba Hydro, and a contract award was made to BBE in March 2014. A third party was also retained to provide a reference proposal, in addition to the engineer's estimate, that also served as a reference point for comparison of the bids.

Slide 35. The general civil contract is a target price contract cost reimbursable contract with a pain/gain share formula that is intended to motivate the contractor to perform. The contractor's profit is at risk. However, their liability is capped at the profit. Once the profit is eroded all actual costs are 100 percent paid by Manitoba Hydro.

The target price contract model was used because the marketplace would not accept a fixed-price contract without a significant cost premium. In addition, all forms of contract require relief for changed conditions. This form of contract is intended to secure competitive bids in a competitive major project environment.

Slide 36 is a timeline showing the construction milestones that have been achieved. Starting with infrastructure, work including the access road, camp, and bridge over Looking Back Creek was built between 2012 and 2014. During NFAT this phase of work was referred to as KIP, or the Keeyask Infrastructure Project.

The general civil contract was awarded in March 2014 and in July of that year the milestone of first rocks in the river was achieved on July 16th, 2014, that signified the start of coffer dam construction which would continue through 2014 and 2015. The start of 2016 also saw the start of construction of the first permanent earthworks, followed by first concrete in the powerhouse in May of 2016. The construction of permanent concrete and earthwork structures has been the focus over the last two (2) years.

So that's looking backwards over the last five (5) years. Now looking forward we'll talk a bit about the future construction milestones. Slide 37 provides a look ahead for the next five (5) years required to complete the work. Starting at the left side of the slide with 2018, this year we'll see the start of turbine and generator installation at Keeyask. And, in fact, our contractor Voith has mobilized and begun work at the site.

Late summer of this year we'll see the

work advance sufficiently to divert the south channel of the river through the spillway. This is a major milestone as this signifies the transition of the river from its natural path through our control -- spillway control structure.

This also permits constru -- construction traffic crossing the river and utilizing the South Access Road to get to the Keeyask site, considerably -- considerably reducing travel time from Gillam. So in the fall of this year the travel from Winnipeg to the site will still be the two (2) hour flight to Gillam. However, rather than an additional two (2) hours on the highway it will be about a twenty-five (25) minute drive from Gillam. So if anyone's travelling a return visit, September-ish is a good time.

Looking ahead to the end of 2019, we'll see the enclosure of the full powerhouse. Currently only the service Bay and unit number 1 are enclosed, while the remaining units are under construction. Looking further to 2020, we would see impoundment of water up against the permanent earth structures followed by the first unit in-service date of August 2021, and the last unit by August 2022.

Slide 38 is another general

arrangement. 362,000 cubic metres of concrete are required to build the powerhouse and spillway. 2.2 kilometres of earth-filled dams are required to construct the North, Central, and South dams. 23 kilometres of dikes are required to build the North and South dikes along the Nelson River to contain enough water to produce power at Keeyask.

This rendering shows the layout of the principal structures at Keeyask. The river flows left to right with the north at the top. Again, the powerhouse is located on the north side of the river, is about one (1) mile from the spillway separated by the central dam. The short dams on the north and south side are also depicted. Keeyask is in a very flat area, so extensive diking is required, as I mentioned earlier, roughly 23 kilometres total.

Slide 39 is a powerhouse rendering. This is an artist rendering showing the powerhouse with the service bay on the right and the seven (7) units progressing leftwards.

Slide 40. This slide shows a time-lapse representation of the powerhouse. On the left and labelled "2015" is the powerhouse excavation progression. In the middle and labelled "2016" is the first year of concrete work showing the lower stages getting off the rock. And on the right and labelled "2017," you can see the service bay and the concrete work on the first three (3) units starting to take shape.

Slide 41. Shown on the left is the first concrete. Leveling and bay slab pours of the powerhouse are shown from early 2016. And shown on the right is the development of the draft to formwork for units 1 and 3. Unit 1 is on the right and unit 3 is on the left.

Slide 42. This is a shot of the powerhouse towards the end of the first year of construction in October 2016. You can see the five (5) tower cranes coloured in blue that serve the work face and are used to lift rebar, formwork, and any material requirements into place. I'd also want to point out the orange tarps that are visible. These are required as part of the heating and hoarding necessary to provide adequate temperatures for the working environment and for concrete curing.

Slide 43. This photo shows the powerhouse complex at the end of 2016, the first year of concrete construction at Keeyask. The model in the bottom half of the slide shows a rendering of the concrete pours completed within the powerhouse in that first year. Again, the service bay is on the right, and moving from the left you see the intake, and moving down you can see the units of the powerhouse, together with the tailrace pour shown on units 1 and 2.

Slide 44. This is another shot of the powerhouse looking upstream from the downstream side of the structure. This was taken in July 2017. You can see there are no orange tarps needed in the summer months. The service bay is on the right, and the units under construction are progressing on the left, starting with unit 1.

Slide 45 is an overhead bird's eye view of the powerhouse in the summer of 2017. You can see units 1, 2, and 3 identified by the circular draft to formwork in the middle of the shot. Progressing leftwards from there, you can see nothing in unit 4, 6, and 7. And the wooden formwork in unit 5 is visible but there's no concrete there.

Slide 46. This photo was taken just prior to Christmas on December 15th, 2017. At that time, you can see that the superstructure steel above units 1, 2, and 3 and the enclosure of the service bay in unit 1 on the right. By February of 2018 units 2 and 3 will be enclosed as well, to permit work continuing throughout the most extreme months of winter.

Slide 47. The previous series of pictures were of the powerhouse. Now I'll show you the spillway, starting with the artist rendering of the end product. You can see seven (7) bays in the spillway, each with its own gate that moves in the vertical direction. This is how we control the flow of the river by moving the gates up and down, increasing or decreasing the open area for water to pass. Also shown here are the upper and lower bridge decks that will connect with the South Access Road and the highway network leading to Gillam. Once construction is complete, the spillway bridge deck will become part of the highway as a river crossing.

Slide 48. This shot of the spillway shows the bay slab, which is the lowest lift of concrete progressing up from the bedrock. The rebar standing vertical and the formwork installation is underway for the first lift -- lift up off the bay slab, which will see the development of the piers starting to take shape. This was July 2016.

Slide 49. By the end of 2016 the spillway was about half complete, as you can see in the shot on the top left. The rendering on the bottom is dated December 17th, 2016, and you can see all of the piers are up off the bay slab, but only a few of them past the halfway point in reaching full height.

Slide 50. By August 2017 nearly all of the piers have reached full height. Preparations are now underway to finish the top lift, strip the forms, and prepare for the installation of the bridge deck.

Slide 51. This shot of the spillway was taken about a week and a half ago. It shows the completed spillway structure. The seven (7) bays are clearly defined and the top deck is in place. You can also see white tarps in the spillway bays providing a heated environment for the spillway gates and guides contractor who is preparing to do their work throughout the winter months.

Slide 52 is a satellite image of the Keeyask site taken in September of 2017. The previous series of slides, I showed you pictures of the powerhouse and spillway, located on this image to the right and on the bottom. They are connected by the central dam, which is the earthwork structure nearly a mile long linking the two (2) structures. The north dam is on the top, running from the powerhouse to the north dike. And the south dam will be on the centre bottom across the south channel linking the spillway to the south dike.

We have a short video prepared and I will pass off to Dave at this point.

(BRIEF PAUSE)

(VIDEO PRESENTATION PLAYED)

THE CHAIRPERSON: Mr. Bowen, I'm just wondering if this is the appropriate time to take the midmorning break.

MR. DAVID BOWEN: Sure.

THE CHAIRPERSON: Okay. So we'll break for fifteen (15) minutes. Thank you.

MR. DAVID BOWEN: Thank you.

--- Upon recessing at 10:34 a.m.

--- Upon resuming at 10:48 a.m.

THE CHAIRPERSON: Mr. Bowen...?

MR. DAVID BOWEN: Thank you, Mr. Chair. Mr. Strongman has walked us through the project features, construction completed in the past two (2) seasons and the basis of the general civil contractor procurement.

I would now like to spend some time describing our challenges with the construction, the permanent earthworks and concrete and what Manitoba Hydro's done and continues to do, deliver the project at the lowest cost and shortest schedule.

I will focus on what happened during the first months of concrete and earthworks construction. This is a time -- timeline from 2014 to spring of 2017. As Mr. Strongman mentioned during his portion of the presentation, the general civil contract scope includes the construction of all dams and dikes; what we've referred to as permanent earthworks and the concrete portion of the spillway and powerhouse; what we refer to -- referred to as the permanent structures.

A major milestone on any Hydro job is first concrete which signifies the start of a new phase, which is building the powerhouse complex. Almost all work prior to this is in support of the first concrete milestone. Concrete began at the beginning of May as planned. There was actually a small amount of concrete placed in the fall of 2015 to test the batch plant and systems. Besides the work, a senior off-site project review team was assembled to carry out a review of the general civil contract work in the spring of 2016 prior to first concrete to ensure that our contractor and Manitoba Hydro were doing everything possible to be successful.

Although this team identified areas of potential opportunity, they were not able to predict the soon-to-be-realized under performance. Concrete colonies were measured daily, and it was evident from the start that production was not meeting plan. At first it was believed that a lag in hiring was the source of the problem and the general civil contractor quickened the rampup of craft labour. It became evident in June that although this slowed the initial production, the plan productivity values were not being achieved.

In June, Manitoba Hydro formally requested a recovery plan which, in simple terms, states the contractor is not meeting their schedule and requires a plan back to get to their original schedule. This plan was developed by our contractor and was put into action in June. You can appreciate the contractor needs some time to prove out whether or not their plan can be achieved and demonstrate they've moved through the learning curve and -- and are able to make a marked improvement, which was expected. The rampup of concrete increased the contractor's workforce from roughly eight hundred (800) people to over fourteen hundred (1400) people in a few months, requiring specialized tradespeople from across Canada.

By the end -- end of July, it was becoming evident that it was less and less likely to occur for the contractor to achieve the original plan.

At the end of August both performance on concrete and earthworks were roughly one-third of where they should have been at this time.

Slide 55. As a result, Manitoba Hydro began to execute a much broader recovery plan which included three (3) parts. The question that needed to be an answer was to determine how do we move forward? Manitoba Hydro -- the Manitoba Hydro project team aggressively pushed our contractor to improve production, as well as developing an immediate and long-term recovery plan. During the fall, a recovery plan strategy was initiated that includes a call to action from BBE's project team, executive sponsors and CEOs. The immediate plan was focused on getting as much work done in the remainder of the 2016 season. This included a winter concrete plan to continue work up to the Christmas break and continue through the winter months.

The long-term plan was focused on what

needed to be done in 2017 going forward. Key work included identify any root causes that are impacting performance; initiating activities to re-forecast the cost and schedule for the project; undertaken an analysis around contractor's claims; supplementing the commercial expertise of our team. These key activities, our own support of helping us understand what to do next.

Slide 56. As noted previously at the end of August, the general civil contractor had achieved one-third of their plan. By the end of the 2016 season they had achieved 41 percent of the concrete plan and 65 percent of the earthworks -- earthworks plan demonstrating improvement, but certainly not where we need to be.

A separate task force was set up to understand the source of underperformance and that would -- then -- then what could be done to cause positive change. Multiple root causes were identified and mitigation measures were -- began to be developed. The main contributing factors were: Aggressive concrete production assumptions from the contractor's bid could not be achieved in the current marketplace; slower than plan progress during the rampup; and challenges that were posed by the geotechnical and geological conditions which impacted both concrete and earthworks.

In addition to these root causes, it was evidenced that we had lost the schedule advancement opportunity of nearly six (6) months that we had coming into the 2016 season, and that we could be facing a delay of two (2) to three (3) years or more.

Slide 57. This is a summary of the recovery plan implementation. There's a lot of content to -- to digest in this summary so don't feel like you need to read all. It summarizes the winter work plan, in other words, getting as much work done in 2016 and containing over the winter months when no concrete had been previously planned; understanding the root causes and a plan to develop mitigations and implement them; review of commut -- commercial options that I will describe on the next slide; understanding claims and contractor entitlement; key interactions with BBE senior leadership, which includes meetings with BBE ownership, accountable for the delivery of their contract which are titled sponsor meetings at the bottom of the page. And lastly, a re-forecast of the schedule and cost for both the general civil contract, and the entire Keeyask project.

Manitoba Hydro had to answer the fundamental question, which was: What is the most cost-effective way to proceed? Alternatives were developed. Manitoba Hydro sought out industry experts to provide advice and guidance from KPMG for the overall recovery plan; Revay for claims valuation and management; Borden Ladner Gervais LLP for legal support; and finally, validation estimating for project contingency development.

Slide 59. The thorough review of alternatives demonstrated the best course of action was to amend the existing contract with BBE. Alternatives were carefully examined based on the risks and impact to both project costs and schedule, and all alternatives guaranteed a substantive increase to costs, schedule, and risk. More detail on the evaluation will be provided tomorrow at the CSI session.

Slide 60. If we go back to the timeline, BBE was required to prepare an updated schedule, estimate and execution plan at the beginning of December in 2016. Manitoba Hydro and BBE -- BBE carried out a detailed review of the schedule first and cost second in December and January to ensure the most effective plan was developed.

This joint effort included the design change to extend the steel columns that support the walls and roof of the powerhouse nearly 10 metres deeper into the concrete. The net effect, to save the project well over one (1) additional year in schedule.

Slide 61. This slide shows the column extenders. On the left-hand side is the -- was the original design and on the right-hand side is the new design.

Slide 62. After the schedule and costs were developed, Manitoba Hydro and BBE were able to negotiate a mutual agreement that provides gives and takes from both parties. It is important to note that there was already a contract in place between Manitoba Hydro and BBE. Changing that contract required agreement from both parties. Manitoba Hydro could not unilaterally change the terms of the agreement without being in breach of contract. The net result lowered the overall costs and schedule risk for Manitoba Hydro and re-established a reasonable profit that BBE could earn back based on their future performance.

Foundational to the agreement was in alignment of both parties' interest to deliver at the lowest cost and shortest schedule.

Slide 63. An amending agreement

formalized these changes and included the following features: All potential claims for the contractor were erased or wiped clean; new schedule and cost incentive pools were established for BBE to provide them an opportunity to earn these incentives, at the same time, minimize project time and costs for Manitoba Hydro; general administration and overhead, which is a real cost for all businesses was capped for BBE at the new target price; for potential future claims the ability claim was narrowed; and finally, liquidated damages for late delivery were established.

Slide 64. Negotiations were completed in January and followed immediately with the update to the project control budget. The control budget is made up of two (2) basic parts: The base estimate and contingency. The base estimate includes all costs to build the work and is based on a realistic schedule, which does not consider all risks. The schedule and costs are then evaluated by a third-party expert, validation estimating, to deter -- to determine a possible range of outcomes and the P50, P75, P90 levels of confiden -- confidence are shown.

In early 2017, when Manitoba Hydro revised the control budget, the Keeyask project budget with a P50 contingency was selected. This established an $8.7 billion control budget to ensure Manitoba Hydro's was proceeding with the lowest cost for execution for the project.

Other alternatives were considered at the time, however, considering the completeness of the project, roughly halfway through the many key risks still remaining, the P50 contingency balances potential costs from the remaining risk and provides a challenge to the execution team.

This approach drives the lowest cost delivery and the most efficient outcome. In addition to contingency, low probability high-impact events were examined to include as project reserves, none were included.

Slide 65. This slide provides a summary of the changes to the Keeyask budget and was included as PUB-MFR-122. It shows a variance from our new control budget established in February 2017 to the control budget established during NFAT of $6.5 billion.

Slide 66. Significant changes were made to cause positive improvement in 2017 for both earthworks and concrete. The concrete works were much more complicated. For example, there was more curved formwork than flat formwork. The work was much higher off the ground and the amount of formwork was over 50 percent more for each placement than the work that occurred in 2016.

Overall, there was a 12 percent increase in concrete volume and a 90 percent increase in earthworks. In addition, the key milestone dates for concrete were achieved, however, despite achieving these milestones, there was a deficit of approximately 20 percent and 25 percent in volume for concrete and earthworks, respectively. And further improvement is required.

Slide 67. This table summarizes the three (3) milestones achieved in 2017, which include the spillway concrete completion, installation of powerhouse crane and in -- in closing the service bay and powerhouse unit 1.

The next two (2) key milestones are on track which include enclosure of units 2 and 3 by February; as well as work complete to divert the rul -- the river through the spillway which will begin in July after the Sturgeon spawn window closes and we could get back on the river again.

This is a photo of the spillway concrete complete in October. The next phase of work is to install the gates, guys and tower and bridge, which has been underway since October and is on track and was previous -- previously shown by Mr. Strongman.

Slide 69. This photo shows the installation of the two (2) powerhouse cranes. These cranes are required to install the turbine engine area parts.

Slide 70. This is the same photo that Mr. Strongman showed you on December 15th, just a different angle. It shows a service bay on the right and unit 1 which are enclosed with roofing and cladding. On the far left you can see the structural steel for units 2 and 3, which is nearly ready for roofing and cladding.

Slide 71. This is a photo from September showing the nearly completed first 600 metres of the central dam. On the top right of this photo you can see the tie-in to the spillway structure.

Slide 72. We have and continue to work with BBE to continually make improvements going forward. We know that we need to improve performance by a minimum 10 percent in the general civil contract to meet the control budget of $8.7 billion. And there is still risk to go. However, we've seen improvements in excess of 10 percent in 2017 and are confident that our team will deliver further improvement. Both Manitoba Hydro and BBE have continued to develop plans to cause positive change in 2018 and are actioning those plans as we speak.

We are not stopping there, and Manitoba Hydro has engaged former Hydro contractors to focus on the general civil contract execution and test these plans to ensure that BBE and Manitoba Hydro are doing everything possible to deliver at the lowest cost and shortest schedule.

As we look forward, the main contributor factors for success in 2018 will include: the 2018 winter work and south dike work which will core -- occur over this winter; continuing to learn from past experiences; earthwork foundation preparation is now complete for 2018 and that work is ready to go as we saw on previous photos from Mr. Strongman. The cold eyes review, which I just referred to, will ensure that we have the best plan going forward.

And finally, Manitoba Hydro and BBE's lead continue to drive improvement at their level of responsibilities for the work.

Slide 73. There are key risks that remain on the project. We are at the halfway point in terms of dollar spent to date and the halfway point for concrete quantity. There are two (2) critical years remaining for concrete and earthworks and more than four (4) years on the project.

Our top risk include successful execution of the general civil contract; loss of site access; work stoppages; unexpected geotechnical conditions. For example, we haven't uncovered the bedrock or the -- where the future south dam will be; and unseasonal weather. We need favourable spring and fall conditions to maximize the concrete window. We need minimal wind days that could potentially stop the crane from -- cranes from operating and minimal wet weather days that slow or stop the earthwork.

Slide 74. Looking at the project as a whole, our current forecast to completion it was with -- is within our control budget and we are currently forecasting the schedule to be four (4) to six (6) months in advance of the control date.

Slide 75. In summary, I'd like to leave -- I'd like to leave you with these thoughts. Manitoba Hydro is capable of the delivery of this project at the lowest cost and shortest schedule and has effective governance. The decision to amend the contract with BBE was the best path forward for the project, and yielded the lowest cost outcome and shortest schedule. Improvements were made in 2017 which saw BBE achieve the key milestones to provide the shortest schedule. Plans are being actioned to cause a 10 percent improvement or more, which is required to meet our control budget.

I would now like to pass it to Mr. Midford.

MR. LORNE MIDFORD: Thank you, Dave. So in summary, Manitoba Hydro has a number of capital projects underway with varying levels of -- of completion, and the project team is focused on managing the risks for the project. We've incorporated lessons learned from across the projects that we've been involved in up to this point.

I can tell you that there's a strong team in place which we've supported by external expertise as well. We're here to be open and transparent. We've shared as much information as we can with MGF and answered any questions that they've asked of us.

And we want the Panel, the Intervenors the public all to know where we are, what challenges we face and how we're addressing them. So, thank you.

MS. HELGA VAN IDERSTINE: And now Mr.

Fogg's going to address the Bipole transmission reliability project.

MR ALISTAIR FOGG: Thank you. Good morning, Panel. As mentioned, I would like to walk through the Bipole III transmission reliability project this morning.

On slide 2, just a quick presentation outline of what we'll cover related to the Bible III project. First, we'd like to go over what is HVDC or high-voltage direct current. We'll walk through the existing HVDC system that Manitoba Hydro has that Mr. Midford touched on briefly earlier this morning. We'll provide an overview of the Bible III project and what is included as part of that project. We'll then provide a status update on the project, and where things stand from a construction and commissioning perspective on Bipole III. We'll discuss the remaining risks on the Bible III project. And then the presentation will end with a quick video similar to that of Keeyask that provides some better context of the size and scope of the project itself.

So Slide 79. Why do we use HVDC or high-voltage direct current for a Bipole III project? HVDC is, essentially, a bulk transmission method. If you were to look at AC power, you know, as an example in the left side of the slide would be similar to that of truck transportation or air. Smaller volumes of material to move but move quickly and can execute from a specialized basis.

HVDC or DC power transmission is more akin to transporting materials on large cargo ships or rail. It's a larger bulk transportation method. There is additional infrastructure required associated with that. But in terms of carrying that amount of material or power, it's more efficient.

Slide 80. So for Bipole III why would we choose HVDC? Essentially, the decision comes down to a breakeven cost analysis on the distance the transmission line needs to cover from the source of the generation of power to where you're trying to deliver that power and the station costs difference between an AC power station and a MR. DAVID CORMIE: or HVDC power station. And what you see in the top left-hand corner of the slide is a picture of an existing HVDC converter station, whereas on the right-hand top corner of the slide is an AC switch yard or station. And as you can see, it provide -- there's a different level of infrastructure and size involved between those two (2) stations.

And considering those two (2) costs and

the distance of the line, essentially, between 600 and 800 kilometres of transmission line is the breakeven distance where HVDC is a more an effect -- cost-effective approach to transmitting power.

Slide 81. Recognizing some of that background on HVDC, we'd just like to walk through the existing Bipole I and II systems within Manitoba Hydro's infrastructure. Now, Bipole I and Bipole II provide a link to -- just around 70 percent of the province's generating capacity.

The picture in the top on the left are the existing Bipole I and II HVDC lines. They are constructed in the same right-of-way and as the picture shows, in some instances are essentially beside one another.

Now, in the picture you can see that each set of transmission lines has two (2) wires, if you will, or cables. Each one (1) of those represents a pole and that is why we would use the term Bipole for each one of those lines as they both carry those two (2) cables.

With -- with recognizing that -- that there's 900 kilometres for each of those lines, and they do traverse both difficult terrain and somewhat inaccessible terrain in the north as well, those lines terminate at a common station which is the Dorsey HVDC converter station.

Going to the next slide, Slide 82. Again, provides just in the -- reference to the province of Manitoba showing where the existing Bipole I and II lines originate in northern Manitoba near Gillam and terminate at the Dorsey converter station. As you'll note, we've essentially represented both Bipoles I and II, with the same line on the graphic as they are that near each other within the same corridor. You can also see on this picture, the location of the Bipole III project, which originates from the Keewatinohk converter station near Gillam and terminates at the Riel converter station just outside the city of Winnipeg on the east side.

Next slide, slide 83. When we look at Dorsey converter station, the terminus point for both of those existing Bipole III -- or sorry, Bipole I and II lines, we need to consider the reliability risk associated with that station. Because it is the single terminus point for those lines, it is susceptible to significant weather events, and in the vicinity of Dorsey, there have been such events in the past. The picture that we've included on this slide is the Elie F5 tornado which occurred approximately 40 kilometres from the Dorsey converter station. A loss at Dorsey could mean the loss of connection to the Northern generation for up to three (3) years to the specialized equipment involved at that station.

Slide 84 speaks to the supply -- potential supply deficit of a loss of either the Bipole I and II line in the winter, or similarly, a -- a loss of Dorsey. What the graphic is essentially showing is that without Bipole III, there would be a supply deficit of approximately 700 megawatts in the system if Bipole I and II or -- and II were lost in the winter of 2020. In comparison with Bipole III in place in such an event, there would be a 1300 megawatt surplus. In the context of -- of 700 megawatt loss, essentially what it would result in is rotating blackouts for about 140,000 homes, even in the event that we had the new 500 kV import line in place.

Slide 85 relates to that same supply deficit and risk, and what this covers is that the maximum percentage of power through a single facility, and by "facility," we would mean the Bipole I and II lines and the Dorsey converter station. Manitoba has the highest percentage of power concentrated in such a single facility for a major network in the world. It can be best described as too many eggs in one (1) basket. The graphic below compares Manitoba Hydro's current HVDC system against those of China, Brazil and Hydro Quebec, which are also hydroelectric-based operations and then shows the improvement in that concentration when Bipole III goes into service.

Slide 86. Really, as we've outlined in the preceding slides, Bipole III is related to increasing the reliability of Manitoba Hydro's system and providing a second corridor for the Northern generation. Bipole III would address the supply deficit of 700 megawatts that could occur with a loss of Bipoles I and II. It also provides the additional converter facility at the Riel converter station, eliminating the single-point risk of the Dorsey converter station.

The second benefit of Bipole III is it does also provide increased capacity of 2000 megawatts, and Bipole III will -- will allow for Keeyask and the associated power sales to be transmitted. Again, the pictures on these slides are showing the 1997 wind events near Dorsey. There was -- we were lucky in some respects, is that it occurred near the Dorsey converter station, just off of Highway 6, a relatively accessible area to address these damaged towers and restore connection to the Northern generation system.

Slide 87 provides an outline of what Bipole III actually includes. Starting from the left-hand side of the graphic, the power originates from the generating stations in Northern Manitoba. That power is collected or put on to five (5) 230 kilovolt lines, which are AC power lines, that bring that power from the generating stations to the new Keewatinohk converter station. The Keewatinohk converter station is -- is one (1) of two (2) stations that form part of Bipole III. It is the northern point on the Bipole III project, and it's about eight (8) -- 80 kilometres northeast of Gillam.

At Keewatinohk, the AC power generated from the generating stations is converted to MR. DAVID CORMIE: power for transmission, and is placed on the Bipole III HVDC transmission line. That transmission line is a 500 kilovolt line that is approximately 1,384 kilometres, which covers from Northern Manitoba to Southern Manitoba, and terminates at the Riel converter station, which is just east of Winnipeg.

At Riel, the power is converted back to AC power from MR. DAVID CORMIE: for use within either the system within the southern part of the Province, or for further transmission south. The other portions not represented in this picture that are important to note is there is a six hundred (600) person construction camp at the Keewatinohk converter station, and additional AC power infrastructure to allow the tie-in to the southern transmission system.

Slide 88 shows a picture of an actual converter station, and I'd just like to walk through some of the components of that converter station to actually show those different pieces and -- and how that functions to bring the power in and execute the conversion. And if we think about this is the Keewatinohk converter station, the power from the generating stations will come in through an AC switchyard, and that's the location where the power is received.

As part of that, we install equipment that are called harmonic filters. As their name suggests, essentially, what they're there for is to filter the AC power that is being received into that station and provide stability. The pow -- the AC power then goes through HVDC converter transformers. There are eight (8) of those transformers at each site, with two (2) spares at each site as well, so a total of twenty (20) of those transformers.

Those converter transformers pass the

power into the HVDC converter building, where the actual conversion from AC power to MR. DAVID CORMIE: power occurs. And the picture that you now see on -- on the slide shows what we would term converter valves, but simply are the pieces of equipment that execute the conversion from AC power to MR. DAVID CORMIE: power.

Once that has occurred, the power leaves the HVDC converter building through a MR. DAVID CORMIE: switchyard, and then is put onto the HVDC transmission line, or the Bipole III transmission line to be sent to the South to the Riel converter station. One unique aspect at Riel that isn't included at the Northern converter station are the synchronous condensers. There are four (4) synchronous condensers at the Riel converter station. They're essentially generators rotating on a horizontal axis to provide stability to the AC system and they're required because we don't have that rotating inertia, if you will, in the South as we do in the North where the conversion occurs right beside the existing generating stations in Northern Manitoba.

Slide 89 provides an outline of the transmission line. As mentioned, the Bipole III transmission line is a 500 kilovolts HVDC transmission line. There are three thousand and seventy-six (3,076) towers starting from the Keewatinohk converter station to the Riel converter station, and the length -- you'll note I've -- here, it states 1,388 kilometres. We noted earlier thirteen hundred and eighty-four (1,384). Thirteen hundred and eighty-eight (1,388) represents the actual constructed length now of the line as a result of a number of smaller group modifications that had to occur. So from plan distance to actual, there is an added 4 kilometres to for minor route adjustments that have occurred through the course of construction.

The five (5) collector lines, or 230 kilovolt AC lines are the lines that transfer the AC power from the stations and from the -- specifically from Henday and the Long Spruce generating station to Keewatinohk, from those five (5) lines, they total 165 kilometres, and there are three hundred and eighty-four (384) transmission towers.

Slide 90 shows a picture of the Keewatinohk converter station taken earlier in 2017. What you can see in this picture in the foreground is the AC switchyard that receives the power from the collector lines, then just beyond that are the converter transformers and the HVDC converter building, and beyond the building, just somewhat more difficult to see in this picture are -- is the MR. DAVID CORMIE: switchyard where the power will then be put onto the HVDC transition line, the Bipole III transmission line.

Slide 91 -- slide 91 shows a similar picture, but now with the Riel converter station, and you'll note quite a bit of similarity between those two (2) stations. Again, this -- this shows us somewhat of a closer picture of the HVDC converter building, where the converter valves are housed, and you can see in that picture as well a better representation of the HVDC converter transformers.

Slide 92 is a picture of the Bipole III transmission line, and in construction and stringing of that line itself, this would be more in the southern part of the Province. What you see in this picture along the ground would be matting, which would provide biosecurity to the crop areas. What it allows for is for trucks and the other vehicles to drive across that matting versus driving through the field itself. As they would exit or enter, they would -- the trucks would be cleaned to ensure that there was no contamination across field to field.

The next slide. This outlines some of

the scope of the history of the Bipole III budget. Shown here is the post-license control budget that was established in 2014 of $4.65 billion, and an in-service date of July 2018 -- end of July 2018. Within that budget, it was a complete project re-estimate from the previous budget for the project. It was based on an updated line routing, an Environmental Act license requirements that had been established at that point. There were updated land acquisition costs included within that budget. The key aspect was it established the LCC, or line-commutated converter HVDC technology that was based on vendor pricing that had been received.

Now, the term "LCC" really relates to just the technology type done for that conversion of AC to MR. DAVID CORMIE: , and would be the same technology used at the Dorsey converter station. As a result of that LCC technology, this budget also included four (4) synchronous condensers at the Riel converter station, and included costs for the community development initiative, or CDI that was part of Bipole III.

If we progress to the next slide, this outlines our current control budget for the Bipole III project of $5.04 billion, and it's still remaining at an in-service date of July 2018. The updates from the previous 2014 budget included actual transmission line construction costs or unit rates from the marketplace, updated transmission line material costs, and some southern route changes. There was further actual land acquisition cost included within this budget, and an increase to the project contingency from a P50 to a P75.

Next slide, slide 95. This outlines the Bipole III status currently. The converter station construction is 91 percent complete at this stage, and the transmission line construction is 84 percent complete. The Bipole III budget is 79 perspent -- percent spent, and is on target, and we remain on target for our in-service date the end of July 2018. At this stage, we have six (6) months of work left to test and energize thousands of components. And as such, right now, we would say the remaining risks are more an impact to schedule versus budget, and I say that largely as many of our contracts contain set dates with our contractors for completion, and liquidated damages or similar mechanisms to address costs if they do not achieve those dates.

So the next slide, slide 96 is a

further update on the Keewatinohk converter station status. At Keewatinohk, all of the HVDC equipment at the site has been installed, and the AC switchyard construction is all complete, and energization of that AC station is now underway. We've also completed the construction of what we would term auxiliary buildings, and those are buildings at the site that provide water for fire suppression systems, and other -- other similar supporting infrastructure.

The next slide is the Riel converter station current status. As with Keewatinohk, all of the HVDC equipment at Riel has been installed. At Riel, the AC switchyard was being expanded versus built from the ground up, and that expansion is complete, and the AC switchyard has been commissioned at Riel. For the Riel synchronous condensers, three (3) of those synchronous condenser units are on site and are under installation. The fourth synchronous condenser unit remains to arrive at Riel, and is just in the final stages of manufacturing.

Slide 98. This is the transmission line current status for Bipole III. Tower and anchor foundation, installation on Bipole III is at 99 percent complete, or essentially complete. With that tower, erection is at 84 percent complete as well.

The remaining focus on the line is tower -- is conductor stringing, and stringing is at 45 percent complete as of January 1st of this year. The transmission line construction will be complete in March of 2018.

Slide 99 provide a bit more context to what we would call the commissioning sequence, or the sequence with which the different pieces of equipment that we've covered are actually brought into service, and then the Bipole III system itself is turned on, if you will. But as I mentioned, at the Riel converter station, the AC switchyard is energized and commissioned already. At the Keewatinohk converter station, we're partway through the energization and commissioning of the switchyard, and by the end of this month, we'll have an operational AC switchyard at the Keewatinohk station.

Following the energization of the AC switchyard, between February and March of this year, we will commission the filters that we discussed earlier that are associated with both HVDC stations as well as the converter transformers, and two (2) of the four (4) Riel synchronous condensers will be commissioned and energized as well within that time frame. Then proceeding further into March of this

year, we will bring into service and commission the
MR. DAVID CORMIE: switchyard at both converter stations, and commission and energize the converter valves within both of the HVDC converter buildings. And by mid-March of 2018, the MR. DAVID CORMIE: line, or the Bipole III HVDC line, will be completed as well. So essentially, by the mid-March 2018 of this year, all of the infrastructure for Bipole III will be installed, commissioned, and energized, and the system will be in place that we will proceed to test.

Slide 100. As we proceed into that Bipole III commissioning, it's important to note the steps that have been taken well before the equipment actually arrives on the site to ensure that when it's turned on or put into service, that it -- it will operate as intended. We've installed quality insurance mechanisms to ensure that the manufacturing of all this equipment that we're receiving meets our technical specifications prior to it ever being placed in service. This includes equipment that is tested at the factories to ensure their technical compliance prior to them being shipped from overseas.

Once on site and once installed, each of those components of our equipment are tested on site and then subsystem tests, or smaller system tests are executed to verify their functionality before being connected to the Manitoba Hydro network. Finally, once that infrastructure is in place, we will energize the system and conduct numerous tests to integrate the Bipole III HVDC system into our existing HVDC network.

Slide 101. To talk -- to think about integrating Bipole III into the existing system, it's important to note what we're talking about is integrating a state-of-the-art, digitally-controlled Bipole III into a system that was designed and constructed in the mid-1960s, 1970s. So there -- there is some risk that goes with that, and we've -- taken the steps to mitigate those risks. That includes -- we've done a simulation of the operations of Bipole III at the factory level through over two thousand (2,000) tests through the control equipment before it was sent from Germany to Canada.

We will then conduct equipment and subsystem tests at the site. By equipment tests that would mean tests individually testing, say, the HVDC converter transformer. Whereas, a subsystem test would be a test of several components of equipment connected together. We will conduct over five hundred

(500) equipment tests, and four hundred and fifty (450) of these subsystem tests.

Once all that infrastructure has been tested at that level, and as -- in mid March 2018, we'll be proceeding to conduct system testing of the full Bipole III system, that is both converter stations and line. And there will be approximately two hundred and fifty (250) tests of that system together before it's brought into service. Finally, at the end of that there'll be a thirty (30) day trial operation which our contractor has to execute to ensure that the full system can be put into the Manitoba Hydro network.

Slide 102. As I mentioned earlier, there are remaining risks and they're primarily schedule risks. From the transmission line perspective the risks are related to both contractor performance and weather. We're in the last construction season of the transmission line. As noted, the transmission line needs to be completed by March of this year.

Therefore, there is risk related to ensuring that it's achieved both from a contractor performance or productivity perspective and weather. Weather can be both becoming warm too early, and making it difficult to construct in winter only construction zones. Or if it becomes too cold then it's difficult to actually stand the transmission towers.

From a converter station perspective, the risk is primarily related to the synchronous condensers and their completion. This is very much connected to a delay in transformers related to those syncs and their delivery. This is probably an important point to tell a small story about the kind of risks that -- that the projects can encounter. With these transformers for the synchronous condensers, they were to be delivered from Italy and there is four (4) of these transformers. These transformers were fully manufactured and the first two (2) were prepared to ship, and we were informed by our contractor that they were no longer able to obtain transportation permits for these transformers.

And on further inquiring learned that because of completely unassociated bridge collapses that had occurred in Italy, the government in Italy had decided to cease issuing transportation permits for larger loads until they could assess the source of those collapses and then also work through the responsibility between municipalities and the overall government of who would be res -- ultimately responsible for issuing such large load permits to allow the transformers to actually make it to the port.

After several months of working through this and developing mitigation plans our contractor, working with the manufacturer and working with Manitoba Hydro, were able to come up with alternatives to barge these transformers down local rivers and actually get to the sea transportation port which minimized the number of permits that ultimately had to be maintained. And they worked with each local community to obtain those -- that smaller number of permits. It was probably about a three (3) month delay, but ultimately it was mitigated to the point that it does not impact the in-service date of Bipole III.

Finally, from a schedule risk perspective is commissioning, and there is six (6) months of work to test and energized these over thousand components. And there is risk that some of those components still do not operate initially as intended. And we do have mitigation plans to address that as well.

So we'll just show a short video of

Bipole III that shows you both the converter stations and the transmission line and some of the infrastructure in its current state.

(VIDEO PRESENTATION PLAYED)

MR. ALISTAIR FOGG: So slide 104. In conclusion, construction is on schedule, and we are on schedule to be in service by July of this year. Budget is tracking to the control budget of 5.04 billion. This will be an asset that is in operation by the end of this year and will be part of the upcoming fiscal year as an asset in operation, and thus the capital cost will begin depreciating for the Bipole III asset this year.

Thank you. I'd just like to pass it over to an update on the MMTP project.

(BRIEF PAUSE)

MR. DAVID CORMIE: Yeah, I think for clarity we're going to do the GNTL project first. Dave, do you have the slides there for that?

(BRIEF PAUSE)

MR. DAVID CORMIE: Thank you. Thank you, Mr. Fogg. Good morning, panel. This section of the presentation will be on the Great Northern Transmission Line. Unfortunately, the bar has been raised and I won't be able to provide you with a video.

First, as background I think it would be helpful for me to explain the overall 500 kV Manitoba/US interconnection project, its components, its purpose, and how it fits into the -- the big picture. The new interconnection is a crucial part of our development plan to meet the future electricity needs of the province. The plan at its core involves the construction of Keeyask, the new interconnection, and several long-term firm export sales to US and Canadian utilities support the plan, improving its economics, reliability, and robustness.

The new interconnection consists of two (2) component transmission projects. In Manitoba the line being built by Manitoba Hydro is the Manitoba Minnesota Transmission Project, and Mr. Penner will speak to the project shortly. However, in Minnesota the Great Northern Transmission Line project is being built by Minnesota Power. In total, the capital cost for these two (2) projects is approximately $1 billion.

(BRIEF PAUSE)

MR. DAVID CORMIE: So slide 3. So what's the purpose of the new interconnection? From an import perspective, the interconnection will increase our firm import capability from 700 megawatts to almost 1,400 megawatts. To put that additional firm import capability into context. that additional megawatts apply capability from the United States is 25 percent greater than the new capacity that is being added to the system by the construction of Keeyask.

The new import capacity will allow us to access MISO market energy when needed in perpetuity. The new import capability will improve energy security during droughts. As a result, it will defer the need for additional dependable energy supplies in Manitoba in the future by as much as the construction of Keeyask will. The line will also improve day-to-day emergency response and system reliability, as we are strengthening our connection to the entire North American electric grid.

Immediately once it goes into service the line will reduce the cost of low water and drought to Manitoba Hydro. We will be able to buy significantly more energy at off-peak prices than we currently can. And the prices that we pay for purchased electricity at the border will improve as they will be more aligned with market prices seen in Minneapolis. These benefits will improve Manitoba Hydro's cost structure in perpetuity.

From an export perspective the interconnection will increase our export capability to the United States by 50 percent, from about 2,100 megawatts to about 3,000 megawatts. This increase will allow us to export more electricity, adding to Manitoba Hydro's income in higher water periods. As well, additional revenue will also be earned as a result of the line, because more of our surplus energy will be sold at on peak prices. In addition, export revenue will improve in almost all years as export prices at the border will be closer to the prices seen at the market in Minneapolis.

And lastly, additional firm export revenues will be generated each year, as firm export sales will not have to be interrupted during the routine interconnection outages we experience, as is now the case. And finally, the Great Northern Transmission Line will increase market access into

Wisconsin from about 100 megawatts that we currently have to 600 megawatts. And that will increase bilateral opportunities to a larger US customer base.

Slide 4. The Great Northern Transmission Line involves a forty (40) year deal with Minnesota Power, the foundation of which is the fifteen (15 year), 250 megawatt multibillion dollar power sale agreement. The deal is a complex arrangement involving several agreements between Manitoba Hydro, its subsidiary 6690271 Manitoba Limited and Minnesota Power. These cost-sharing agreements cover construction costs, property and capital taxes, operating costs, and sustaining capital.

As is it's not a Manitoba Hydro project, the construction cost contributions payable by 669 are not in Manitoba Hydro's capital expenditure forecast. However, they are included in the IFF. The cost will be capitalized as an intangible asset and amortized out over forty (40) years. To these annual costs are added 669's ongoing share of GNTL taxes and operating costs, and all of these costs are included in the IFF.

What is important from a risk perspective is that Manitoba Hydro is ultimately responsible for the majority of GNTL costs, 72 percent. And that -- and given that, most of the costs are incurred during construction. Now is the time during which we need to be most vigilant and active in protecting our interests, and we are doing that to our subsidiary 669.

Slide number 5. Manitoba Hydro established its subsidiary 669 for US tax and liability reasons related to the project. This company is responsible for representing Manitoba Hydro's interests in the development and construction of the line. It raises the capital it needs by issuing shares to Manitoba Hydro.

The GNTL is being built under a facilities construction agreement between Manitoba Hydro, the Midwest independent system operator, and Minnesota Power. The facility construction agreement commits Minnesota Power and 669 to pay for the up-front construction costs of the line.

The other significant agreement is the construction management agreement between Minnesota Power and 669. This agreement appoints Minnesota Power as the construction manager with the responsibility to physically build the line. Importantly, though, it establishes a governance structure for project decision-making that gives 669 significant oversight and control through consultation and ultimately veto rights, with the independent advice and help from an oversight engineer.

This is slide 6, and it illustrates the governance structure of the project. At the bottom on the left-hand side you can see Minnesota Power is the construction manager. The construction manager reports to the management committee, which has one (1) representative from Manitoba Hydro's subsidiary 669 and Minnesota Power.

The management committee has approval responsibilities in preconstruction, contracting, bidding, and construction areas. The independent third-party engineer also respor -- also reports to the management committee. Should there be a dispute at the management committee, the issue is raised to the executive level. If not resolved there the issue goes to binding arbitration.

Slide 7. As we sit here today, Minnesota Power is active in construction in northern Minnesota with a workforce of over four hundred and fifty (450) people working on all segments of the line. All major permits and approvals are in place. As a large portion of the right away is through very remote and wet terrain, the project is dependent on favourable winter constriction -- construction weather to minimize access costs. As a result, the project has -- has built an extra year into the schedule to provide for the option of delaying work if a mild winter occurs.

So far, the winter weather conditions have been ideal and significant process is being made on clearing and foundation work. The project is on schedule for in-service on June 1st, 2020. To date the project is on budget with approximately 10 percent of the funds spent. Manitoba Hydro has the expectation that the project will be under budget given the conservative nature of Minnesota Power's budgeting process.

With that I'd like to turn the mic over to Mr. Penner who will now speak about the Minnesota Manitoba transmission project.

(BRIEF PAUSE)

MR. GLENN PENNER: Thank you, Mr. Cormie. Good morning, panel. I would like to take a few minutes to explain a few more details around the Manitoba portion of the project, and as Dave explained we call the Manitoba portion of the project MMTP or Manitoba Minnesota Transmission Project.

The control budget for the MMTP is $453 million based on the final preferred route, the current schedule, and in service of June 2020. The picture shown here on this slide is the existing 500 kV transmission interconnection. The new line will look very similar using latticed steel structures.

The project consists of 213 kilometres of 500 kV line and modifications at three (3) stations: Dorsey, Riel, and Glenboro. The line begins at Dorsey and follows the existing corridor south of Winnipeg and east almost to Vivian where it takes a southeast path towards the RM of Piney where it crosses the international boundary.

Station modi -- modifications consist of the following: Dorsey, a500 kV line termination to connect the 500 kV line into the Manitoba Hydro system; at Riel, an additional transformer bank will be constructed; and at Glenboro phase shifting transformers and realignment of the transmission line. Glenboro is connected into Rugby, North Dakota, and is another interconnection. This phase shifting transformer is required to move power into the US once the MMTP project is in service.

The 500 kV line can be broken down into two (2) portions. The first is 92 kilometres on existing Manitoba Hydro owned corridor. It's beside other transmission lines. And the second is 121 kilometres in new right-of-way. The existing corridor will contain all self-supporting structures. The new right-of-way will contain approximately 50 percent of self-supporting structures and 50 percent of guide structures. Guide towers are used primarily in nonagricultural and in wetlands. Self-supporting structures are used primarily in agricultural land where a smaller footprint is required to access around the structures.

It is important for project success to have a project execution plan. The plan will define roles and responsibilities for the project and how Manitoba Hydro will deliver the project. The picture on this slide is of a Bipole transmission project during the stringing operation. The Transmission Projects Department at Manitoba Hydro is responsible for project management, which includes preparing and coordinating estimates, preparing schedules, and capital justification documents. They will be responsible to manage the ongoing activities to coordinate design and construction through project completion.

The Transmission Design Department at Manitoba Hydro is responsible for the design of the overall line, including structures and foundations. They are also responsible to develop all of the drawings, and tender all of the material required for the transmission line.

The Transmission Construction Department at Manitoba Hydro is responsible to put together the construction tender and then oversee the construction and ensure that the contractor hired constructs the project according to the design and meets the requirements and conditions of the environmental license. Station modifications will be designed within Manitoba Hydro and then the majority of the construction work will be completed by an external contractor.

The 2013 budget for the project was $350 million, which was revised to 453 million in 2016. There are a number of factors that influenced the decision to increase the budget. At the time, routing selection was complete, allowing a better estimate of required towers and tower types.

There -- there was an increase to self-supporting towers and a decrease in guide structures which resulted in a cost increase. Modifications to the phase shift transformers at Glenboro was that an increase to the cost. We updated the market prices based on results that we received from Bipole III, and so it reflected our most recent tender prices. And the estimate was increased from P75 probability estimate, which means that it has a 75 percent chance of being at or below the $453 million estimate.

In the transmission projects group at Manitoba Hydro, we are continually improving and adjusting how we do things based on past experiences. Bipole III is the latest project, which has been under construction for the past five (5) seasons. Prior to Bipole, the team was responsible for the construction of Wuskwatim transmission as well as Herblit transmission projects in the past ten (10) years.

Direct lessons learned, including changes to the routing methodologies, improved indigenous engagement, inclusion of bio-security in Bipole III and in MMTP, evaluating and changing how we do contracting models as well as construction methods. And we've also had opportunity to share some of these lessons learned with Minnesota Power and their GNTL project.

So where we are and where we've come

from. So between 2012 and 2015, we were involved in the environmental assessment and the public engagement process. In 2013 we received an Order in Council issued by the province to proceed with -- with the environmental assessment. In 2014 NFAT recommended this project to proceed. In 2015 we filed our environmental impact statement with the province. In 2016 we filed the application with the National Energy Board.

In 2017 we went through the clean environi -- sorry, the Clean Environment Commission hearing and review. In 2016 and 2017 we started detailed design, material procurement, and currently we are 10 percent of the budget spent, approximately $44 million. In 2017 we started property acquisition. In 2018 we will go through a National Energy Board hearing and review, and we anticipate a provincial license decision sometime in 2018. And we are estimating construction sar -- start sometime in 2018 or '19, depending on when we received regulatory decisions. And we have a June 2020 in-service date.

I will now pass the presentation back to Dave.

(BRIEF PAUSE)

MR. DAVID CORMIE: Thank you, Mr. Penner. This will be the last presentation, and it will be on the Manitoba/Saskatchewan transmission project. The need for a new transmission line between Manitoba and Saskatchewan is the result of an agreement reached in 2016 between Manitoba Hydro and SaskPower for the sale of 100 megawatts of system power. We first advised the Public Utility Board of the sale and the need for the line following the signing of the term sheet in September of 2015.

Energy deliveries will commence on June 1st, 2020, and will continue for twenty (20) years. To put the sale in perspective, it will require the equivalent of 18 percent of the capacity and 13 percent of the average energy production from Keeyask.

MS. HELGA VAN IDERSTINE: Mr. Cormie, can I just stop you for a second? Thanks. Does the panel have the presentation? Okay. Thanks.

MR. DAVID CORMIE: As the majority of the existing firm export capacity to Saskatchewan is reserved for other uses, transmission studies indicated that an additional transmission line was needed to make the sale feasible. The current schedule indicates that the in-service date won't be until June 1st of 2021, for that line which is a year later than the date when SaskPower needs the capacity and energy.

In the meantime, if the new line is actually delayed by a year the agreement allows for partial delivery using interim firm transmission service that's available to both companies. We are working on plans to ensure that as much of the hundred megawatts of capacity can be made available on June the 1st of 2020 as possible. In its review of the Saskatchewan sale agreement and transmission project, the Board's independent advisor, Daymark, has concluded that both the contract and the transmission line project remain economic.

In Manitoba, Manitoba Hydro will be responsible for building the Birtle transmission project. It's a relatively small project in comparison to Bipole III or the MMTP project. From a licensing perspective, it's a class 2, and Manitoba Hydro is engaged in significant public consultation for the line. The cost, based on a 2015 estimate, is $57 million.

Thank you. That completes my testimonial. I'll now let Mr. Midford summarize today's presentation.

MR. LORNE MIDFORD: Thank you, Mr.

Cormie and thank you to the Board for giving us the opportunity this morning to give you an update on all five (5) of these projects. I've had in my career the opportunity to work with each of these panel members in some way or another, and I can tell you that we are very, very fortunate to have this level of expertise working on our projects.

For all five (5) of these projects a common thread for all of them is that we're committed and -- and some might even say driven to providing these projects at the lowest cost possible, because we know that's the expectation of everybody in this room, and also of our customers as well.

For Keeyask, we are projecting to be on budget and on schedule. We're still four (4) ways away from being in service. And at this stage in the project we think it's appropriate the numbers that we've put forward for our control budget and schedule. We don't believe it's appropriate to overstate those potential costs and to reflect that in the rate base this early.

For Bipole III, as you've heard, we're on schedule and on budget for in-service July of this year. And, of course, that will impact the '18/'19 financials.

For MMTP we're on budget, with a projected in-service date of June of 2020. The Great Northern Transmission Line, you've also heard that the budget may be high, but we are on schedule at this early stage to meet the in-service of June of 2020.

And for the Saskatchewan transmission project, the budget is currently under review and our current in-service is June of 2021.

That concludes our presentation this morning, and if it's appropriate, I'd like to open it to questions.

THE CHAIRPERSON: Thank you, Mr. Midford. In fact, we'll take the lunch break at this moment. We'll break for lunch and return at one o'clock. Thank you.

--- Upon recessing at 12:06 p.m.

--- Upon resuming at 1:03 p.m.

THE CHAIRPERSON: Good afternoon. We're going to have questions from the Panel, Ms. Kapitany, I understand you wanted to proceed?

THE VICE-CHAIRPERSON: Thank you, Mr. Chair. I have a couple questions. One was alluded to by Mr. Strongman who is -- back in the front row. It was around labour productivity, I believe. You talked about productivity having declined over the last number of years. I just wondered if you could talk a bit more about that. It seems counterintuitive that productivity would've declined.

(BRIEF PAUSE)

MR. JEFF STRONGMAN: So the remarks that were made -- I believe I made reference to productivity having declined in the last twenty (20) to thirty (30) years. The first thing to consider is that the remarks are made in reference to Keeyask, and there was a large gap in time between Manitoba Hydro's last generating station project that was a Conawapa -- excuse me, the Limestone project initiated in the '80s and completed in 1990 -- '92 I believe. And then the next station that was Wuskwatim started in 2006 and completed in 2012 and that fifteen (15) year gap led to a lot of people leaving Hydro industry following the completion of Limestone and not having generating stations on the books in terms of construction projects throughout Canada, actually, not just here in Manitoba, there was a gap in experience and -- and knowledge within Hydro construction.

So specific to productivity on Hydro stations that that's one (1) of the points. And the second is generationally the productivity issues are very different from the previous generation to now, with a wide range of more socioeconomic based explanations behind that. Higher regulatory obligations with respect to environment and -- and safety that has had an impact on productivity and something as simple as every person having an iPhone and not necessarily keeping it off until break time.

THE VICE-CHAIRPERSON: We call it NFAT. We did talk about the lessons learned from Waskwatim and some of those lessons -- Mr. Bowen, I think it might've been you spoke about that. Some of those lessons were then to be transferred to Keeyask.

Could you speak about that a little?

MR. DAVID BOWEN: Are you -- are you asking lessons learned specific to labour productivity?

So -- so in Wuskwatim, I think Jeff -- Mr. Strongman was trying to give us the context of the overall marketplace, and -- and not only in -- in the -- the type of work that happens on a generating station which is a heavy formwork type of work where there's many erosion of productivity that's happened right across Canada. But the same erosions happen if you look and studied the offshore gulf oil and gas work. It's -- it's the same erosion that's happened from the '80s onwards and it's -- it's -- it's at least a decline by half of the productivity was achieved.

But in terms of -- to your question about lessons learned Wuskwatim, the challenges we had at Wuskwatim were around the attraction/retention of -- of qualified craft labour and it was really in the generating station build phase. So, the time where we were doing the work we showed in the last two (2) years at Keeyask so the -- the -- constructing the concrete, the formwork, et cetera, and -- and a lot of back in the Wuskwatim time and just go back in -- in -- in history a little bit is that the Canadian marketplace was very hot and there was a great deal of competition right across the country for labour and -- and when you work at an isolated fly-in/fly-out facility, that -- it's -- it's -- that stress and strain on the marketplace is accentuated.

And so at -- at Wuskwatim we had -- our contractor had challenges with getting really good people there and keeping them there and, to some extent, we haven't had those same challenges at

Keeyask. We've had -- the execution challenges we've had at Keeyask are -- are -- are different and the same.

The -- the mitigating measures we put in place -- when we talk about attraction/retention is one of the first things we did for Keeyask back in 2014 was we actually did a study across all remote northern projects about the -- the labour piece. How much -- how much money is a craft labour worker going to put in their pocket on a weekly basis as they make the decision to either come to a job or stay. And -- and so we actually have a retention bonus that equalized -- raised the Manitoba rates which were the lowest in the country under the Burntwood Nelson Agreement to -- to something better. It wasn't the same as Alberta but it was better and it has an incentive to keep people here. That's one -- one mitigation.

I think other mitigation was this early contractor involvement process to -- to award the -- the scope as -- as Mr. Strongman stated for the earthworks and the concrete together as -- as one (1) contract that wo -- that scope was broken up during the Wuskwatim contract and it -- it was to allow the contractor almost two (2) years to plan out the work for the concrete, understand the marketplace and -- and -- and get ahead of the potential risk for not only attracting but retaining or training staff.

So those are -- those are two (2) mitigation measures in place that we -- that we put in place. Probably some of the most significant in terms of the strategy piece, in terms of the effectiveness while they haven't -- I guess from a Manitoba Hydro perspective, they haven't been as effective as -- as we had originally planned them to be.

THE VICE-CHAIRPERSON: Thank you. My second question is for you, Mr. Midford. It's from the last page in the slide deck that you presented this morning, under the Keeyask generating station section.

You've got a bullet in there that says:

"Several opportunities to reset for ratesetting purposes, if necessary."

You didn't speak to that bullet. Could you expand on what you meant by that?

MR. LORNE MIDFORD: What I meant -- so Keeyask in -- where it's at in terms of its phase of execution, there's four (4) years left until it's in-service, and we believe that -- there's a lot of talk about different classes of estimate, P50, P90, P75.

So I -- we believe that the P50 properly reflects the level of contingency at this phase in the project and that that level of our control should be reflected in terms of rate setting.

And the -- as the project continues if there is a requirement to revisit that, then they'll be those opportunities down the road. That was the point of that.

MS. HELGA VAN IDERSTINE: Ms. Kapitany, I think Mr. Strongman wanted to expand on the -- his answer after -- with respect to the first question you asked so if you don't mine.

MR. JEFF STRONGMAN: One (1) thing I would like to add is when we were talking about the -- the generational difference in productivity. One (1) of the key pieces of comparison is the -- the duration of rotation. A crew rotation going in and out of a remote site, historically, has been considerably longer than what current industry norms are. In previous projects that Manitoba Hydro has undertaken decades ago, thirty-five (35) days in a row and forty-two (42) days in a row were normal durations at site. And in the current environment that we're building Keeyask fourteen (14) and seven (7) and twenty-one (21) and seven (7) are the normal rotations.

So on a fixed period of time you have people away longer and greater travel expenses to get them back and forth from home and the -- the job site. So that, again, has an impact on group continuity and another things that erode productivity. Thank you.

THE CHAIRPERSON: Ms. McKay...?

BOARD MEMBER MCKAY: Just trying to understand the person hours that are listed because some are listed in person hours, some are percentages and wasn't quite sure what the total number of person hours was but you indicated on a later slide.

I just wanted to find out about the Indigenous employees, you have 4 million person hours listed, does not include the 2 million person hours for the KCN members?

MR. JEFF STRONGMAN: I -- I believe the -- the numbers that had been provided in the section of the Keeyask presentation that I provided had covered 15 million person hours to the end of 2017, of which 2 million hours were performed by our KCN partners and of which a total of 4 million out of that 15 was performed by Indigenous people.

BOARD MEMBER MCKAY: So let's 2 million plus the 4 million; is that what you're saying?

MR. JEFF STRONGMAN: Pardon me, I think it's slide 25. I'd just like to double-check with the reference.

BOARD MEMBER MCKAY: Yes, it is.

MR. JEFF STRONGMAN: Yes. So slide 25 shows 2 million person hours worked by our KCN partners, our members, and 4 million by the Indigenous employees of any location throughout Canada.

BOARD MEMBER MCKAY: Okay. So that's 6 million in total for Indigenous employees?

MR. JEFF STRONGMAN: Yes, the two is part of the four. Sorry, I wasn't sure that's what meant.

BOARD MEMBER MCKAY: Yeah, I kind of thought that. So, amongst your three (3) groups, there for Indigenous employees, all Manitobans and others? Your Indigenous employees would be the lowest number of person hours, correct?

MR. JEFF STRONGMAN: Sorry, I don't think I understand your question.

BOARD MEMBER MCKAY: Well, the question is, you have 73 percent total hires are Manitobans?

MR. JEFF STRONGMAN: That's correct.

BOARD MEMBER MCKAY: Okay. And 27

percent, I would presume are from outside of Manitoba?

MR. JEFF STRONGMAN: That's correct.

BOARD MEMBER MCKAY: That's 73 percent, I think works out to -- well, it's a total of 10,000 -- 10 million 50,000 so your Other would be 4 million 50,000 and your Indigenous employees would be six thousand (6,000) in total; if I was reading that right.

But it -- it might actually even be lower than because I was assuming that the Indigenous employees -- that the KCN members were not part of the 4 million, you were accounting for -- for Indigenous employees.

I'm just trying to clarify whether the Indigenous population has the lowest number of person hours on the site.

MR. JEFF STRONGMAN: Okay. Let me try and provide some clarification. On slide 28 we've stated that 15 million person hours have been worked on the project to the end of 2017 by all peoples.

Of those fifteen (15) 73 percent of them are Manitoba hires. That doesn't actually refer to the number of hours worked by Manitobans, but it's saying that for everybody hired on this job 73 percent of them have been Manitoba.

So I can't answer your question mathematically the way that you're asking it because we don't have the number of hours worked by the 73 percent of the employees ever hired. I think what you're trying to do is take 73 percent of those 15 million and say roughly 10 million. And then what percent of those are by the KCN and -- and Indigenous but we haven't calculate it that way and I can't confirm that that math is correct.

BOARD MEMBER MCKAY: Can we get an undertaking on that?

(BRIEF PAUSE)

MR. JEFF STRONGMAN: Could you clarify what the undertaking would be?

BOARD MEMBER MCKAY: The breakdown of person hours for the 15 million person hours.

MR. JEFF STRONGMAN: Yes.

--- UNDERTAKING NO. 52: Manitoba Hydro to provide a breakdown of person hours for the 15 million person hours.

BOARD MEMBER GRANT: Can I just get a -- I think it's about the Bipole. I think it's slide 19 of the Bipole slides, sorry.

Now, you mentioned in-service date of July 2018. I was just comparing that to the last bullet where it's a -- whatever risks remain they're about scheduling as opposed to budgets.

So I guess it's two (2) questions. One: What is the risk of not hitting the in-service date of July 2018? And the second one it's just -- it's the juxtaposition of schedule and budget and I'm wondering if these are completely independent of each other. If you miss the in-service date, are there any budget implications whatsoever?

I understand with the generating station there are obvious ways in which a delay affects the budget but, in this case, are there any economic costs to not hitting that in-service date?

MR. ALISTAIR FOGG: Well, I think to -- to probably answer part 1 and part 2 of your question is -- both of those are and, really, in fact related to another.

So, if you would look at the comparison between budget impact and schedule impact, certainly, a project such as Bipole III from a cost-impact perspective were it to come into service later, would have additional costs, for example, related to interest and escalation or carrying costs before it was capitalized; very similar to a project such as Keeyask would have.

Where some of that may differ from a cost perspective is depending on contract model or contract type. For example, if converter station contracts would be in -- in the fixed-price arrangement, that contractor would still have -- be executing that under the same costs so there wouldn't be their overhead -- additional overheads for those additional time, plus they may be subject to penalty for being delayed, depending on the contract.

BOARD MEMBER GRANT: So if there is any -- so I guess going back to the first question then: What is the risk of not hitting the in-service date and then some order of magnitude or proportion of -- what would be the budgetary consequence; minor, large, sign -- you know?

MR. ALISTAIR FOGG: So in -- in terms of risk of not hitting in-service date, I guess, broadly speaking, the first risk starts to become continued exposure to reliability issues that we've been exposed to to date related to outages on Bipole I and II or she's at Dorsey. That -- that's what I would say is the -- the primary risk of not achieving the in-service date with Bipole III and extending that -- that risk out as time goes by.

Risks of not hitting that in-service date, otherwise, would -- really would be a balance between those -- those overhead -- sorry, interest and escalation costs counted against any potential amounts we can recoup from contractors for that.

BOARD MEMBER GRANT: Sorry, I wasn't clear in my question. What's the probability that you won't be ready to go by July 2018?

MR. ALISTAIR FOGG: I wouldn't have a specific probability assessment around that date; that being said, certainly based on where we stand right now construction progress wise and -- and the commissioning plan in place, we have a high degree of confidence of achieving that.

There's numerous months to allow for testing and potential issues that could arise during testing and to address those within that timeframe that we're working from today to July 2018.

BOARD MEMBER GRANT: And -- and if you were a month late, beside from interest and escalation, significant economic costs or --

MR. ALISTAIR FOGG: No, I would say in -- no, not significant. It would be some additional internal costs, project management costs. But again, I think we would be looking to recuperate some of that as well.

BOARD MEMBER GRANT: Okay, thank you.

MR. DAVID CORMIE: And, Dr. Grant, one (1) of the benefits of Bipole is the reduction of losses associated with Bipole III. And I'm -- I'm not sure what the megawatt amount was; something less than 100 megawatt. So, the earlier Bipole III comes in; the more power will be available for export.

If you used a thirty dollar ($30) a megawatt hour for a month would be a -- be a couple million dollars of -- of -- of reduced income that we had in the IFF associated with an in-service date of July. Let's say it was in-service date of August, that one (1) month of delay would mean that we would have less export revenue.

BOARD MEMBER GRANT: And sorry, that's because of less transmission loss?

MR. DAVID CORMIE: Losses, yes.

BOARD MEMBER GRANT: Okay, thank you.

MR. DAVID CORMIE: The -- the -- with Bipole III in-service, the MR. DAVID CORMIE:

transmission system is more efficient.

THE CHAIRPERSON: I have a few questions. I don't know who -- I'll just throw them out and whoever wants to answer them can answer them.

Bipole III you show a budget for 2016 of five billion 42 million (5,042,000,000) is that P50 or P75?

MR. ALISTAIR FOGG: That's P75.

THE CHAIRPERSON: Okay. MMTP 216, budget of 453 million. Is that P50 or P75?

MR. ALISTAIR FOGG: That's at P75.

THE CHAIRPERSON: Okay. Keeyask 8.7 billion is P50, correct?

MR. DAVID BOWEN: Correct.

THE CHAIRPERSON: We have evidence in this hearing that P90 is 9.6 to 9.9 billion, depending on the -- the delay, correct?

The evidence was if it's twenty-one (21) month delay it's 9.6 billion, if it's thirty-two (32) month delay it's 9.9 billion; that was -- that was put forward by Mr. McCallum.

MR. LORNE MIDFORD: Okay. From a project perspective, the 9 -- are P90 is 9.6.

THE CHAIRPERSON: Okay.

MR. LORNE MIDFORD: With -- with that

corresponding twenty-one (21) month delay.

THE CHAIRPERSON: Can you explain to me why -- so in your budgets then -- can you explain to me why certain things are shown in your budgets as P75, and other things, are shown as P50?

I'm having trouble understanding why Keeyask is shown as a P50, but these other projects are shown as P75.

MR. LORNE MIDFORD: I'll -- why don't I take a first crack at that and I'll leave it up to other panelists to -- to provide project-specific answers.

When a P50, P75, P90 estimate is developed, it's based on the risk assessment, various risks. There's a risk register for each of these projects given where they are at any given point in time, and each of those risks has a level of probability, and if you can think of it as a -- kind of a distribution curve as such.

So -- and then based on that, there's a mathematical analysis, Monte Carlo analysis, of all of those different permutations, commutations of those probabilities to derive what is perceived to be a P50 level estimate, P75 level, or a P90 level estimate.

So it's really a reflection of the

risks of each of the risk elements within each of the projects. And quite often it's based on understanding of what those risks are and exposure of those risks with -- for each of the different projects.

So for Keeyask, for instance, where we're at in terms of -- about 50 percent spend, and about 50 percent of the concrete that's been placed. With the risks moving forward and four (4) years of construction still ahead of us, we feel that the P50 is appropriate for where we're at in the project at this time.

These other -- some of the other projects are further along, and some of those risks and the risk profiles have changed as they get closer to -- to the in-service date or -- and so that -- so they do their own analysis and develop their own risk profiles.

THE CHAIRPERSON: Mr. Midford, do you have the geotech for the south dam? My understanding is you are still waiting. There's a -- there's a slide, I'm not going to look at it, that talks about that being one (1) of the biggest risk factors is that -- you haven't done the geotech for the south dam.

MR. LORNE MIDFORD: Yeah, the geotech underneath the existing waterway.

THE CHAIRPERSON: Right. So how is it a P50 then if you've got that kind of risk? I'm just -- I'm trying to figure out -- I understand the P50 and the P75 and it deals with risks and risk assessments, but you've identified the geotech as being one (1) of your biggest risks, but the budget given to us is still on a P50.

MR. DAVID BOWEN: I -- I'm going to try and answer the question.

THE CHAIRPERSON: Okay.

MR. DAVID BOWEN: I think you're asking the -- I'll -- I'll take a step back. So the -- the P50 value whether or not the geotech risks exist to the south dam and whether that quantum is 10 million or $100 million, that's what would vary based on the level of confidence. So knowing that that risk occur -- is -- is there just, for example, if that risk value at a P50 was $100 million, at a P75 the value carried in the budget would be something like, say, $140 million and a P90 would be something like $190 million.

So the -- the risk exists there, it's just -- it's how much money we -- we would carry in the budget at -- at a different confidence level. So I'm not sure if that answering your question.

THE CHAIRPERSON: So if you're -- if the geotech has a worst-case scenario, what you're saying is you've already assessed what that would be and relate that to the overall budget and determine whether it's P50 or P75?

MR. DAVID BOWEN: I guess -- almost. What -- what I'm saying is that we know that risk exists, that the amount -- the risk is the probability of occurrence times the impact.

So at a P50 level if the dollar amount in our budget would be the least amount and as we would increase in confidence of not overrunning, it would -- the dollar value would be higher. So that risk event, it's the same risk event that's carried but the dollar amount is higher as we move up from a P50, 75, 90, et cetera.

THE CHAIRPERSON: Okay. Can we --

MS. HELGA VAN IDERSTINE: Before we move on, I think that Mr. Penner might want to comment on --

THE CHAIRPERSON: Okay.

MR. GLENN PENNER: MMTP we do -- we're carrying a P75 estimate currently for it. And I guess the question could be begged that we are not as far along as Bipole III. However, given that we're working on the heels of Bipole III, we are very confident in what our construction contracts will be and tower steel prices are -- are -- have been pretty stable. So we feel that the P75 estimate is -- is something that -- that -- that makes sense to present at this time where it is in the project.

THE CHAIRPERSON: Thank you, Mr. Penner. Could we go to page -- I have it as number 10. I think it's probably 86. We're using different page numbers. No, sorry -- yeah.

This makes reference to 1997 Wind Events near Dorsey. Was that at -- at a level of an F5 or was that less than an F5?

MR. ALISTAIR FOGG: I don't believe it was specifically a -- a tornado event --

THE CHAIRPERSON: Okay.

MR. ALISTAIR FOGG: -- that occurred but it was -- it was a wind event, essentially, a large wind event that caused that issue.

THE CHAIRPERSON: Okay. And this is Bipole tower that went down? The mangled tower on top, is that a Bipole tower?

MR. ALISTAIR FOGG: Correct that wasn't -- that was in 1996 I believe.

THE CHAIRPERSON: Seven it says.

MR. ALISTAIR FOGG: 1997. And yes, there were nineteen (19) structures on both Bipole I and Bipole II that -- that came down. It was in September and it was a wind event that Environment Canada referred to as a microburst. They did not refer to it as a tornado.

THE CHAIRPERSON: And do you know how far from Dorsey it was?

MR. ALISTAIR FOGG: It was -- it was right at Highway 6 so it was probably 10 kilometres north of Dorsey, kind of in that range, little bit less.

THE CHAIRPERSON: Okay. Maybe you're the one to ask then, Mr. Penner, on page 83, the F -- that's an F5 tornado. It says:

"A loss at Dorsey could mean loss of connection to northern generation for up to three (3) years."

This was 40 kilometres from Dorsey. I assumed that if it gets that close to Dorsey we're looking at a major problem not only for the lines, but for Dorsey itself; is that correct?

MR. GLENN PENNER: If a tornado were to be a direct hit to Dorsey, there -- there would be major damage. It would be -- it's hard to predict how much damage, but -- but Dorsey is a very critical piece of infrastructure because until the Riel sectionalization was built, it was the only tie between the HVDC, the 500 kV AC interconnection and the 230 system that is the backbone at Manitoba Hydro.

THE CHAIRPERSON: So if you've got a tower -- if you've got towers within 40 kilometres, which is where this tornado was, and they got -- they were hip by the tornado, I assume that we -- we're going to have problems with those towers?

MR. GLENN PENNER: Correct.

THE CHAIRPERSON: Okay.

MR. ALISTAIR FOGG: And just -- just to add to that, the three (3) years at Dorsey references replacement of -- of equipment such as the converted transformers that we discussed previously. So due to their special nature, the lead time in remanufacturing and having those delivered to Dorsey could cause that three (3) years lost connection.

THE CHAIRPERSON: Okay. Page 82. You've got the map of Bipole and relation of Dorsey. How far is Bipole from Dorsey?

MR. GLENN PENNER: Are you referring to Bipole III?

THE CHAIRPERSON: Yeah, Bipole III,

the line that is west of Dorsey, how far away is that?

MR. GLENN PENNER: I'm not sure exactly how many kilometres but it was planned to be at a distance away and that's why it terminates at Riel and then travels east and south away from Winnipeg and Dorsey. It's certainly much further than 40 kilometres.

THE CHAIRPERSON: Okay. Elie is which direction from Dorsey? It would be west, wouldn't it?

MR. GLENN PENNER: Yes.

THE CHAIRPERSON: Okay. The tornado -- the Elie tornado came from the west; is that correct?

MR. GLENN PENNER: I'm not -- I'm not sure which direction it would've come from.

THE CHAIRPERSON: If I go up further north for Bipole III to immediately west of Jenpeg, what's the difference between Bipole -- what is the distance between Bipole III and Bipoles I and II?

MR. GLENN PENNER: I'm not sure what -- what the distance is between Bipole III and Bipoles I and II at that -- you're talking about that specific location where --

THE CHAIRPERSON: Yes.

MR. GLENN PENNER: -- they get closer.

THE CHAIRPERSON: Yes.

MR. GLENN PENNER: Correct. Yeah, I'm not sure -- I -- we would have to get an undertaking to get --

THE CHAIRPERSON: Well, if I could get an undertaking to determine the distance at that point. I think Mr. Penner --

MR. GLENN PENNER: Yeah, they were just giving you some background on the design requirements for that location. So, in those locations where we had to move as part of the -- the requirements to get closer to Bipole I and II, we pro -- we designed the structures to withstand a higher wind load. So the structures are reinforced in that area, but I -- I don't have the information as to exactly how close those structures are.

THE CHAIRPERSON: Well, could you provide an undertaking to determine what sort of wind it could take and -- and whether it could withstand a F5 tornado?

As I understand it, based on the information here, if an F5 tornado hits at that point, we've lost all the Bipoles, unless somebody tells me otherwise.

MR. GLENN PENNER: No -- I can -- I

can get an undertaking. But an F5 tornado, it -- it can -- it's a very specific and can be very focused in terms of its energy and I guess the best way to describe it is it's not -- it's not like a large wind event that -- that could take out multiple spans.

A tornado is a very specific type of storm and -- and it can be on the ground for very short periods of time. But I -- we can provide some information through an undertaking.

--- UNDERTAKING NO. 53: Manitoba Hydro to provide the distance between Bipoles III and Bipoles I and II at its point immediately west of Jenpeg. Then further to what level of resistance from when they've been built.

THE CHAIRPERSON: Okay. As I look at the -- as I look at the photo -- so the undertaking is that they will provide the distance between Bipoles III -- Bipole III and Bipoles I and II at its point immediately west of Jenpeg. Thank you and -- and I guess then further to what level of resistance from when they've been built.

Mr. Penner, when I look at the map on page 82, I guess the -- the actual map of the Riel converter station on the right is a better depiction than where it shows on the actual map? I mean, when I look at the -- the sort of the map on the left, it looks like Riel is south of Winnipeg. It's actually more east of Winnipeg, isn't it?

MR. GLENN PENNER: The map -- the air photo on the right is -- it's maybe a better depiction. I think the -- the word "Winnipeg" on that large-scale map may -- there's no dot indicating where Winnipeg is and I think that's -- that may be why -- there's a dot that indicates Selkirk, but there's no dot for Winnipeg.

THE CHAIRPERSON: Yes.

MR. GLENN PENNER: So it's -- it's -- if you -- it's just north of the Deacon's corner where the reservoirs are.

THE CHAIRPERSON: Okay and the -- and if I was going to the United States from Riel I'd go south or southeast of Riel to hook into the United States with GNTL and MMTP; is that correct?

MR. GLENN PENNER: MMTP actually

connects into Dorsey and it goes -- the -- the line actually follows -- it follows south of Winnipeg, but just south of Winnipeg, south of the perimeter and follows an existing corridor and then -- and then it actually comes up past Riel station and follows along an existing corridor just past Anola and you can see that on that page 82, and then it turns south/ southeast towards the RM of Piney.

THE CHAIRPERSON: Okay. Thank you very much.

MR. DAVID CORMIE: Mr. Chairman?

THE CHAIRPERSON: Yes.

MR. DAVID CORMIE: If I could add to the conversation about the risks of the Bipole -- associated with Bipole III. I think it was at our rate hearing last year, Dr. Swatek addressed this issue and provided a -- a comprehensive presentation on -- on -- on the probability of -- of -- of losses with and without Bipole III.

And I think it would help you understand the -- the change in risk profile that we have with Bipole I and II going to Bipole III. We would provide you that. It's -- it's -- it's quite illuminating.

THE CHAIRPERSON: Thank you, Mr.

Cormie, I'd appreciate that. Okay, Mr. Peters...?

MR. DAVID CORMIE: Yes, Manitoba Hydro will provide the presentation Dr. Swatek presented on the risks of reduction associated with the construction of Bipole III.

--- UNDERTAKING NO. 54: Manitoba Hydro will provide the presentation Dr. Swatek presented on the risks of reduction associated with the construction of Bipole III.

CROSS-EXAMINATION BY MR. BOB PETERS:

MR. BOB PETERS: Good afternoon to the Panel. I'd like to start by repeating an off-mentioned admonition that no questions of mine are to seek responses that contain information that Hydro believes is confidential or commercially sensitive.

My questions are only seeking to elicit succinct answers, but if you feel to answer my question properly for the Board that you have to include confidential information or information that Manitoba Hydro has not been required to put on the public record, please let the Board and your counsel know that you will respond fully to that question when we go in camera tomorrow.

Would that be understood and acceptable, Ms. Van Iderstine and Ms. Mayor?

MS. HELGA VAN IDERSTINE: Yes, that's acceptable, thanks.

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: And thank you. So I want to start my questions starting with Keeyask, and we're going to start in Board counsels' volume 6 of the book of documents on page 5. And to get us started, my questions will be for whoever chooses to answer from the panel, recognizing you have your -- your specialties.

The Public Utilities Board was told at the Needs For And Alternatives To review that Keeyask had a starting price at about $6.2 billion as would be seen by following the CEF-13 line item down to Keeyask where they intersect; is that correct?

MR. DAVID BOWEN: During the -- the NFAT, at the start of the NFAT hearing, the budget was indeed $6.2 billion. Before the -- the hearing was concluded, the budget was changed to $6.5 billion.

MR. BOB PETERS: And you told us that on your slide 34, that we don't need to go to Mr. Bowen, but it was during the course of the NFAT that Manitoba Hydro received its bids back from the four (4) contractors who were responding to Manitoba Hydro's tender; is that correct?

MR. DAVID BOWEN: That's correct.

MR. BOB PETERS: And as a result of getting the four (4) bids back, Manitoba Hydro analyzed them, and Manitoba Hydro made a decision to accept a tender from a general civil contractor that resulted in the total cost of Keeyask coming in at 6.5 billion; correct?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: And you told us on slide 32 of your presentation what's included in the general service contract -- general civil contract, it's the moving of the earth, the building of the earth structures, the building of the mechanical structures once the concrete is in place; correct?

MR. DAVID BOWEN: That's -- that's a good summary of the scope, yes, correct.

MR. BOB PETERS: And equally what's important is -- and I think you told us this as well, Mr. Bowen, that not included in the general civil contract for Keeyask would be what you referred to as the Keeyask Infrastructure Project, which included roads, power, there was a camp, as well as the turbines, the generators, the gates, the hoists, and the other hardware that engineers like?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: All right. That $6.5 billion, Mr. Bowen, was the total in-service cost and that includes interest that's been capitalized on all the money that's been paid out; correct?

MR. DAVID BOWEN: That's right, it was our P50 estimate --

MR. BOB PETERS: Yeah.

MR. DAVID BOWEN: -- at the time of the NFAT.

MR. BOB PETERS: All right, we'll -- we'll come to that a little bit later, but the -- the essence of looking now at -- back on page 5 of Board counsels' book of documents, and we can go over to your capital expenditure forecast number 14, follow it down, and we see 6.496 billion that we've rounded off to 6.5; correct?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: That 6.5 billion was supposed to be the all-in cost, if I can call it that;

correct?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: And not only did it include interest, it included things like escalation, which was really analogous to an inflation adjustment over -- over the years?

MR. DAVID BOWEN: Once again it was our P50 value at that time.

MR. BOB PETERS: All right. And the 6.5 billion forecast included a first unit in-service on November 2019, if I recall?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: Now on page 6 of Board counsels' book of documents, we move past 2014, and there was no update, was there, and into 2015 and the capital expenditure forecast was not revised; was it, Mr. Bowen?

MR. DAVID BOWEN: Correct. There is no update in 2015.

MR. BOB PETERS: Why was there no update in 2015?

MR. DAVID BOWEN: There was no reason to update the control budget in 2015.

MR. BOB PETERS: Everything was looking at?

MR. DAVID BOWEN: I wouldn't say everything was looking good. A project like this has many risks but we didn't have any reason to believe that we were going too push past the 6.5 million in 2015.

MR. BOB PETERS: All right, but by mid-2016, Manitoba Hydro has engaged a group called the Boston Consulting Group.

You're aware of that?

MR. DAVID BOWEN: I'm aware that when the Manitoba Hydro Board was replaced, the -- one of the first things they did was to engage the Boston Consulting Group on behalf of the Board and that occurred I believe in the May/June timeframe of 2016.

MR. BOB PETERS: Would you be aware, Mr. Bowen, that at the same time the Manitoba Hydro Board or even before that, the Manitoba Hydro Board engaged KPMG Consulting Firm?

MR. DAVID BOWEN: I'm not aware that the Manitoba Hydro Board engaged KPMG.

MR. BOB PETERS: Was it Manitoba Hydro's management that in -- in -- Mr. Midford, can you help me out here?

MR. LORNE MIDFORD: I think you may be referring to the project team hiring KPMG to do a health check of the project perhaps.

MR. BOB PETERS: All right. And that was in May -- or sorry, that was in early 2016?

MR. LORNE MIDFORD: Yes.

MR. BOB PETERS: It's appended to your rebuttal evidence if you need a date but...

So the difference, Mr. Bowen, is it was Manitoba Hydro's Board of Directors that engaged the Boston Consulting Group, and it was the Manitoba Hydro executive that engaged KPMG at or about the same time.

Have I got that right?

MR. DAVID BOWEN: The -- the project team engaged KPMG.

MR. BOB PETERS: The project team is Manitoba Hydro?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: When you look on slide -- or page 6, I should say, of Board counsels' Exhibit 42-6 and Boston Consulting Group tells Manitoba Hydro that the cost of Keeyask will increase from 6.5 billion to 7.8 billion without any mitigation steps being taken by Manitoba Hydro and that will result in July '20/'22 in-service date; correct?

MR. DAVID BOWEN: Yes, that's what it says on -- on their slide.

MR. BOB PETERS: And you're aware that's what they told Manitoba Hydro or were you not aware of that?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: If Manitoba Hydro was to mitigate some of the concerns, Boston Consulting Group suggests that the in-service cost would still increase from 6.5 billion but would be more in the range of $7.2 billion with an in-service date probably in the August of '20/'21 range, correct?

MR. DAVID BOWEN: Yes, that's what -- that's what their analysis shows.

MR. BOB PETERS: You're aware of their analysis when they were doing it?

MR. DAVID BOWEN: They were working -- yes, they were working with my team at the time they were performing the analysis. However, our team did not perform this analysis. This is an analysis done by BCG.

MR. BOB PETERS: On slide -- sorry, on page 7 of book of documents 42-6, the Boston Consulting Group had some recommendations that would help mitigate the schedule.

You're aware of that, Mr. Bowen?

MR. DAVID BOWEN: Yes, I'm aware of

that.

MR. BOB PETERS: Did -- did Boston come up with those on their own or was it really Manitoba Hydro telling Boston that these are the steps that would mitigate the concerns?

MR. DAVID BOWEN: I would say the items identified here really came from our Manitoba Hydro team.

MR. BOB PETERS: All right. And not to get in any great detail but I think you mentioned in your slide this morning, Mr. Bowen, that to install powerhouse columns to enable parallel construction was really putting, and this is in my words, metal girders on cement at a lower stage of the cement construction so that something could be built on the top of those metal girders while somebody also worked underneath them on the cement -- or concrete?

MR. DAVID BOWEN: What I was just trying to say is that, yes, we could lower the elevation of the concrete and -- and for giving -- for correcting the structural steel columns and -- and really what -- what it enables to do for the site is that the -- the work is constrained by the winter months. So being able to get the columns up sooner and, of course, the cladding and roofing on sooner allows work to -- to continue over the winter months and allows us to mitigate schedule.

MR. BOB PETERS: And you told the Board this morning, Mr. Bowen, that that mitigated the schedule by as much as twelve (12) months?

MR. DAVID BOWEN: Yes, without -- without using column extenders we -- we would be facing another one (1) year delay or more.

MR. BOB PETERS: Was there a similar or some comparable time savings to using the backup power to replace the short-term need for the auxiliary building?

MR. DAVID BOWEN: It -- no, no, this was -- this is showing for the spillway structure and so, no, the -- the timesaving was not nearly as great.

MR. BOB PETERS: Was there, in fact, any timesaving to the overall schedule?

MR. DAVID BOWEN: I'd -- I'd have to -- to check to see what exactly that was. I don't have that answer on my fingertips.

MR. BOB PETERS: All right. Well let's look at the third -- the third performance improvement really focused on improving the general civil contractor's productivity and effectiveness; correct?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: How does Manitoba Hydro do that?

MR. DAVID BOWEN: That's a -- that's a really big question. And I -- so I think the question you're asking is: How does the Manitoba Hydro make sure that our contractor, in this case, a general civil contractor is providing the best result for Manitoba Hydro.

There's a number of things that we do and, really, I'll go back to the beginning and I'll go back to the GCC procurement. So I think what Mr. Strongman noted originally in his -- in his presentation was that at the time the general civil contract was put to tender, we went through an exhaustive two (2) year process. We engaged experts. We -- we attempted to match the risk that the marketplace would use -- would -- would be able to take at that time, and to ensure that we could get the best price for all -- all of Manitobans.

At the same time, we engaged a company called Chant Construction. Chant actually did a shadow bit at the same time to help validate our cost; to make sure that when those prices came in that they closed. There's -- there's one (1) example.

Really, other examples in terms of effect we manage risk. We -- we went through the process for the early contractor involvement where we brought our BBE, general civil contractor, in early in the process to help mitigate risks. It's -- it's -- it's hard to say -- because we don't have the project going on at the same time without doing the ECI compared to -- with the ECI, it's hard to provide an apples-to-apples comparison. But really, it's -- it's a best in class procurement methodology that's used in industry to help the contractor to mitigate risk and be ready for construction.

Those are just a few examples of what Manitoba Hydro is doing to provide the best value -- value for Manitobans.

MR. BOB PETERS: Thank you, Mr. Bowen, we'll come to some more of that. Before I leave page 7 of Board counsels' book of documents number 6, that chart, does that show the Board in a graphic how far behind the concrete placement was in those various years?

MR. DAVID BOWEN: So I believe you're referring to slide 7 in the book of documents --

MR. BOB PETERS: Yes.

MR. DAVID BOWEN: -- and you're --

you're referring to the graph on the bottom right corner, which shows the volume of concrete in April '16, May, et cetera.

So, yes, it shows, for example, if we look at May '16, there was plan to place 42,000 cubic metres of concrete at that time, and by month end we had 13,000. So it -- it shows that deficit, yes.

MR. BOB PETERS: All right, I've got some further questions about that, but I wanted to just cover the price at a high level, and we're going to leave the Boston Consulting Group prices of between 7.2 and 8.5 billion, Mr. Bowen, -- let me rephrase that.

It was Boston who quantified the in-service costs of Keeyask to be between 7.2 and 7.8 billion; correct?

MR. DAVID BOWEN: That's what the report says on slides -- slide 6, yes.

MR. BOB PETERS: And that's what they told Manitoba Hydro?

MR. DAVID BOWEN: Yes, that's what they told our -- our board.

MR. BOB PETERS: And your board didn't accept that because on page 8 of the book of documents, we see your board chair, I believe makes an announcement that the control budget of Keeyask is $8.7 billion, and that announcement was in approximately March 7th of 2017; correct?

MR. DAVID BOWEN: Yes, that's correct.

MR. BOB PETERS: Can you explain to this Board why the Boston Consulting Group's price forecasts were not accepted by Manitoba Hydro?

MR. LORNE MIDFORD: The board hired Boston Consultants to come in and they evaluated the -- the project in the very beginning of the construction where the concrete was being placed in May, June and part of July.

So Boston Consulting did a forecast based on that initial sliver of time looking at the productivity and they did their best to forecast where the project could end up.

That wasn't a change in the control budget or control schedule, that wasn't a detailed analysis of all the risks associated with the project, which is what the project team did at the -- at the end of the construction season. And then with that new information, they updated the control budget with a direct recommendation to our Manitoba Hydro Board with the -- with the new control of $8.7 billion.

MR. BOB PETERS: Thank you, Mr.

Midford. On page 11 of Exhibit 42-6, MGF Services provides what I'll call a waterfall diagram to depict what's happened in the Keeyask generating price going from 6.5 to $8.7 billion.

Do you see that, Mr. Bowen?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: And the largest increase to get from 6.5 to 8.7 was due to which contract?

MR. DAVID BOWEN: The general civil contract.

MR. BOB PETERS: And we can see that on the next page as well, on page 12, that schematically the general civil contract was driving the majority of the cost increase taking Keeyask from 6.5 to $8.7 billion; correct?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: Now, Mr. Bowen, you personally didn't want to accept that $8.7 billion cost from the Manitoba Hydro Electric Board. So it looks like on page 13 of Board -- of Board counsels' book of documents that you challenged your construction team to bring Keeyask in at $8.2 billion, with only an eleven (11) month delay.

Do you see that? It's going to be on

the right-hand side of this -- and I'm not sure how --

MR. DAVID BOWEN: I see it, yes.

MR. BOB PETERS: All right. And -- and when I said "you," I guess it was personal you; was it not?

MR. DAVID BOWEN: This -- on Exhibit 13, this is what we call our Keeyask project manager -- project manager update. So Manitoba Hydro, as the project manager, provides this publication about quarterly mainly to our KCN partners to provide information on the project.

MR. LORNE MIDFORD: I might just add that this -- we consider this to be a stretched target for the project team and that was presented to our board at the same time that the new control budget was approved.

So the project team itself has a -- has a target to better the existing control budget and schedule.

MR. BOB PETERS: But Mr. Midford, it's not accepted by the Manitoba Hydro Electric Board?

MR. LORNE MIDFORD: It's considered a -- a stretch target.

MR. BOB PETERS: Okay. I'm not familiar with that concept, does that mean it's --

MR. LORNE MIDFORD: You're striving to achieve that, yes.

MR. BOB PETERS: Striving to achieve it. It's still considered realistic; is that correct?

MR. LORNE MIDFORD: (No Audible Response).

MR. BOB PETERS: As -- as we sit here today is that cost estimate still valid?

MR. DAVID BOWEN: By the math -- as I mentioned in my presentation, we require a 10 percent improvement in the general civil contract work this year. And we -- we can't have any major risk come true in order for it to -- for us to meet our control budget.

In order for us to do -- to push down towards $8.2 billion, that is significantly a -- a stretch goal, we would have to have upwards of a 30 percent improvement in our general civil contract to come close to that right now.

MR. BOB PETERS: So if we turn just quickly to page 50 of Board counsels' book of documents, we'll see a chart with a schedule of dates that was prepared not by Manitoba Hydro but I want to understand when we look at this schedule, Mr. Bowen, the October 17, 2020 in-service target is no longer the -- the stretch target or the plan date.

Would you accept that?

MR. DAVID BOWEN: Sorry, can you repeat the question?

MR. BOB PETERS: Let me ask it this way, Mr. Bowen. If your stretch target could be achieved and you've now indicated that to achieve it you'd need a 30 percent improvement in this next year, when would the first unit come in service?

(BRIEF PAUSE)

MR. DAVID BOWEN: I was just trying to make sure I got my math right here. So the -- we -- we would need over a 30 percent improvement, as I previously noted. The -- the stretch goal that we referred to, the 8.2 billion, has a first unit -- first unit in-service date of October of 2020.

MR. BOB PETERS: Would it be realistic at this point, Mr. Bowen, to conclude that that's not going to happen?

MR. DAVID BOWEN: Certainly from a -- from my perspective and our team's perspective, we are going to continue to drive to have the lowest cost and shortest schedule. I guess it depends who you ask whether or not it's realistic. It is a very tough goal that we are going to continue to work at, and I'd be happy to report back here at the end of this construction season and -- and give you a real answer of how realistic it is or not.

MR. BOB PETERS: All right, we'll make a date. No, it's certainly not an undertaking.

In the discussion you had with the Chair just after the lunch recess today, the understanding is that the $8.7 billion is the P50 number, and you stressed that repeatedly, Mr. Bowen; correct?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: And just for the record, the -- the designation P50 indicates that there's a 50 percent chance the cost will be lower, and also a 50 percent chance the cost will be higher than 8.7 billion?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: And catching up to what the Chairman talked with your President and CFO about on page 15 and 16 of Board counsels' book of documents, maybe we'll see it over the top of 16, we can see that with no in-service delay beyond '20/'21, the P90 would be 9.6 billion but that would increase to 9.9 billion if there was a further delay; correct?

MR. DAVID BOWEN: Yes, that's what's shown here.

(BRIEF PAUSE)

MR. BOB PETERS: Mr. Bow -- sorry, Mr. Bowen, your slide 64 from your presentation this morning...

(BRIEF PAUSE)

MR. BOB PETERS: I just want to make sure the -- the Board here is clear that going from Manitoba Hydro's P90 on page 64, your slide 64, that contemplates a delay of not only eighteen (18) months, but an additional eleven (11) months as noted above that, correct?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: So that's a twenty-nine (29) month delay from what was first estimated?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: And if -- if the P90 number was calculated based on what I believe was being spoken about in response to this information request of a further delay or a thirty-two (32) month delay, that thirty-two (32) month delay is, in essence, only three (3) additional months from Manitoba Hydro's P90 of April 22 -- April of 2022, and a nine point six (9.6) number?

MR. DAVID BOWEN: So -- so to clarify, the -- the P90 value provided on slide 64 has a twenty (20) minu -- twenty-nine (29) month delay. In the reference books of documents here on -- on item 16, there is a farther three (3) month delay noted to move the twenty-nine (29) month delay to thirty-two (32) months, and there is additional interest and escalation that that would attract. I haven't run the numbers personally, but the -- the values show here that it would increase from 9.6 to $9.9 billion.

MR. BOB PETERS: Thank you. And you -- you answered better than I asked it, but you can confirm that to go from Manitoba Hydro's P90 of $9.6 billion to the P90 at $9.9 billion, that's an additional three (3) months and only three (3) months, according to the information?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: Thank you, sir. Mr. Bowen, is Manitoba Hydro in the process of updating its Keeyask cost estimate?

MR. DAVID BOWEN: No. No, we have -- we have monthly construction cost reports, and we have our contract -- our -- our staff are continually projecting, but we're not going through a formal update at this time.

MR. BOB PETERS: Is there an update being done for the schedule?

MR. DAVID BOWEN: Yes. Yes, the schedule is driven by the general civil contract work. Because there's been change in the schedule, it impacts the entire job. Right now, as we speak, our Manitoba Hydro site team is working with BBE to update the Keeyask schedule based on expected progress for 2018. Once that occurs for the general civil contract work, of course, there is a knock-on effect to other site contracts, and that work will happen and exp -- expected to happen and be complete in -- in the next month.

MR. BOB PETERS: By the end of February, 2018?

MR. DAVID BOWEN: Correct.

(BRIEF PAUSE)

MR. BOB PETERS: Mr. Bowen, can you

through your counsel undertake to provide that information to the Board when it's received?

MR. DAVID BOWEN: It's -- just want to confirm what you're asking. You're asking for our updated control schedule at the end of February?

MR. BOB PETERS: Or as soon as it's received, yes.

MR. DAVID BOWEN: I -- we -- we can provide that.

MR. BOB PETERS: Thank you, sir. Mr. Bowen, your undertaking was to -- to provide through your counsel the Public Utilities Board with an update of Manitoba Hydro's schedule for the completion of Keeyask?

MR. DAVID BOWEN: Yes. Yes.

--- UNDERTAKING NO. 55: Manitoba Hydro to provide the PUB with an update of Manitoba Hydro's control schedule for the completion of Keeyask at the end of February or as soon as it's received

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: And, Mr. Bowen, if that schedule either adds more days or subtracts more days, does that impact the cost?

MR. DAVID BOWEN: Absolutely.

MR. BOB PETERS: And will Manitoba Hydro take steps to update its Keeyask cost estimate after it gets its schedule estimate?

MR. DAVID BOWEN: So the -- the schedule I'm referring to, we have our control schedule, and -- and I think everyone recognizes what the control schedule is. So our first in-service date is -- for our control is August of 2021. We have what we call a working schedule, and the working schedule is dynamic, and this working schedule is the schedule I was referring that's being developed with the general civil contractor as we speak.

This schedule will outline the work that's going to happen this year in the 2018 sea -- season. Once -- once the -- we establish what work happens under the general civil work, we'll then look at what work happens under the turbine engineer work with Voith. We'll look at the intake, et cetera, to make sure everything is knitted together, and -- and we have all the logic ties, right? So -- so normally we would not do an update of our cost estimate unless there was a significant change to the working schedule. From -- from what I know right now is that we -- we were -- the -- the change is going to be such that we do not plan to do an update of our costs based on the schedule.

MR. BOB PETERS: Thank you for that, Mr. Bowen. If we turn to page 50 again in Board counsel's book of documents, Exhibit 42-6, Mr. Bowen, I want to make sure the panel is with you on that last answer. Manitoba Hydro's control data is shown as August 2021, correct?

(BRIEF PAUSE)

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: And that's for the first unit to be in-service and operational?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: Even with this updated schedule done with the general civil contractor, Manitoba Hydro is not planning to change the control date of August, 2021?

MR. DAVID BOWEN: I just want to make sure we're -- we're talking correctly, the terminology. The control date references our $8.7

billion control budget. Our working schedule is that our team's goal is to achieve the work -- to finish the work as quickly as possible to mitigate costs. Of course, we're not going to give up on safety, the environment, quality, and our -- and our commitments under the JKDA. So -- so I would expect the information that I received back from our construction team will be in advance of the control date, because that's what everyone's working to is to -- to come in at the -- the shortest amount of time.

MR. BOB PETERS: Thank you, sir. I'd like to turn to an issue to explain to this panel the increase in prices for Keeyask that wen -- went from 6.5 to 8.7 billion with my next questions. And probably the best way to start, Mr. Bowen, is to pick up some of your comments by looking at page 25 of Board counsel book of documents. At the end of 2016, Mr. Bowen, there were problems that were identified by Hydro by the Boston Consulting Group, and I suppose by KPMG, correct?

MR. DAVID BOWEN: Yes, it was evident at the end of 2016 that we had done -- like it says here, it was actually about 40 percent of our planned concrete work, and about 60 percent of our planned earthworks.

MR. BOB PETERS: And when we try to drill down with this question as to what was the reasons for that, Manitoba Hydro had three (3) main reasons. The first was the labour productivity was a problem. There was also a slower than planned ramp-up on site, and then there was some geotechnical issues and concerns, correct?

MR. DAVID BOWEN: That's correct. And -- and if -- if the Board likes, I'd be prepared to talk at more detail on -- on these items tomorrow.

MR. BOB PETERS: All right. You're inviting the Board to -- you want to provide something to the Board -- and that wasn't very cryptic, but in the -- in the in-camera session?

MR. DAVID BOWEN: Yes, I'd be willing to provide greater level of detail tomorrow.

MR. BOB PETERS: All right. So I'll just ask Ms. Van Iderstine, or Ms. Mayor to make a note of that and they will ask you the appropriate question in-camera. That would be acceptable. Thank you.

(BRIEF PAUSE)

MS. HELGA VAN IDERSTINE: Yes, we will

do so.

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: On the public record, Mr. Bowen, which of these three (3) main issues is the largest driver of the increase in costs of Keeyask going from 6.5 billion to 8.7 billion?

MR. DAVID BOWEN: I would say let me look at these three (3) -- three (3) bullets. The -- the difference between the bid and the actual production achieved -- product to be achieved is the -- is the largest driver.

MR. BOB PETERS: So that's the productivity factor that's mentioned in -- in one (1) of those three (3) bullets?

MR. DAVID BOWEN: Yes. Yes, in the first bullet.

MR. BOB PETERS: And is it the productivity for both the startup of the concrete placement in 2016, and also the actual productivity for concrete placement once the contractor got mobilized in 2016?

MR. DAVID BOWEN: The -- the actual productivity achieved from startup right through the season was -- was far greater than what was expected.

MR. BOB PETERS: I'm sorry, I'm not sure I heard your answer correctly.

MR. DAVID BOWEN: The -- the productivity rates achieved, the person hours per unit of work, they were much larger than the bid from the start of the construction season throughout the entire construction season.

MR. BOB PETERS: What you're saying is Manitoba Hydro's expected productivity never materialized from the general civil contractor?

MR. DAVID BOWEN: Well, what I'm saying is that both Manitoba Hydro's expectation and our contractor's expectations were not achieved.

(BRIEF PAUSE)

MR. BOB PETERS: Mr. Bowen, where did Manitoba Hydro get its expectations as to productivity with concrete and earthworks?

MR. DAVID BOWEN: In terms of where -- where we derive our productivity rates from, it comes from our past historical experience. So from Limestone, Wuskwatim, Pointe du Bois. It comes from working with other utilities across Canada, and it also comes from, in this case, I mentioned the -- the shadow estimate that was done during the general civil contractor bid. So it comes from all those different areas.

MR. BOB PETERS: Did Manitoba...

(BRIEF PAUSE)

MR. BOB PETERS: Mr. Bowen, can you indicate whether Manitoba Hydro, in its original contract with the general civil contractor, use the same productivity rates for concrete and earthworks that Manitoba Hydro actually achieved when it constructed Wuskwatim?

MR. DAVID BOWEN: No. The rates for lower.

MR. BOB PETERS: Manitoba Hydro's expectation of productivity was lower -- let me rephrase the question. Manitoba Hydro expected there to be greater productivity on Keeyask than Manitoba Hydro achieved on Wuskwatim?

MR. DAVID BOWEN: That's correct.

MR. BOB PETERS: So where in Manitoba Hydro's past history did Manitoba Hydro achieve the productivity rates that it was expecting in its contract with the general civil contractor on Keeyask?

MR. DAVID BOWEN: The -- the rates provided by the general civil contractor would have been during the Limestone era.

MR. BOB PETERS: So for the panel to understand, the general civil contractor included in that bid productivity levels that were similar to what would have been achieved by Manitoba Hydro in the Limestone construction?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: Did Manitoba Hydro verify how the general civil contractor could achieve those productivity levels?

MR. DAVID BOWEN: During the -- the bid analysis phase, this was a -- obviously a -- a topic of concern and discussion. It was one (1) of the reasons why we carried a significant labour reserve in our original control budget, albeit it -- in hindsight, it wasn't adequate, but yes, yes, we looked at that in -- in earnest.

MR. BOB PETERS: What you're telling this Board is that when you received the general civil contractor's bids for productivity, a red flag went up that caused Manitoba Hydro to want to check into that further?

MR. DAVID BOWEN: Correct. As part of

our bid evaluation, we -- we look at the prices, and -- and certainly this one was a concern for -- for the team doing the analysis during the procurement phase.

MR. BOB PETERS: And the contract, the general civil contractor that Manitoba Hydro -- Hydro hired was a joint venture consortium of -- you told us this morning -- Bechtel Canada, Barnard Canada, and EllisDon, correct?

MR. DAVID BOWEN: That's correct.

MR. BOB PETERS: Have -- and -- and it's all -- its shown as BBE, and perhaps that's the legal name that they use? Is that how it's known?

MR. DAVID BOWEN: Yes. It's much easier to say.

MR. BOB PETERS: Thank you. Did BBE construct other Hydro projects that Manitoba Hydro could verify their productivity levels on?

MR. DAVID BOWEN: Bechtel was part of a joint venture that was involved with Limestone, so that was a Bechtel/Kumagai joint venture. Barnard has done some Hydro work, albeit quite a bit smaller in -- in the US. And -- and EllisDon, they're -- they don't have direct experience within the -- the Hydro marketplace, but certainly, they have more experience within the Canadian construction marketplace.

MR. BOB PETERS: And the three (3) of them haven't joined together to do any Hydro project that Manitoba Hydro is aware of?

MR. DAVID BOWEN: I'm not aware of that JV doing any other -- other Hydro projects like -- like this, no.

MR. BOB PETERS: So help the Board understand that once Manitoba Hydro saw that the productivity level being quoted in the general civil contract proposal by BBE, was it -- was it -- was similar to what was achieved back in the Limestone days, what investigations did Manitoba Hydro do to determine whether that was reasonable going forward?

MR. DAVID BOWEN: I think the -- the largest investigation we did was bringing on -- doing a -- the shadow estimate that I talk -- just talked about by having a contractor do a shadow estimate on the bid to help verify those values.

MR. BOB PETERS: Was that shadow contractor doing that work before the bids were received from the four (4) proponents?

MR. DAVID BOWEN: Yes. I -- you're -- you're testing my memory, but I believe that the estimate from the shadow estimate was received at the same time that the bids were -- were closed.

MR. BOB PETERS: And you're prepared to share what those bids are tomorrow with the panel?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: All right. Thank you for that, sir. Mr. Bowen, in some discussion you had just after lunch -- lunch with the Vice Chair, you've previously told not only the Vice Chair, but the members of the Board who were on the Needs for and Alternatives rou -- review panel that there were lessons that Manitoba Hydro had learned from the Wuskwatim construction, and that was going to give Manitoba Hydro greater confidence when it embarked on Keeyask, correct?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: And one (1) of the -- and I'm looking on page 34 of Board counsel's book of documents. One (1) of the reasons for that greater confidence was because dealing with Keeyask, Manitoba Hydro had already awarded the general civil contract by the time the Needs for and Alternatives review was being conducted. Do you recall that?

MR. DAVID BOWEN: Yes, I do.

MR. BOB PETERS: And the essence of that, Mr. Bowen, is because the general civil contract had been issued for Keeyask and was included in that

$6.5 billion number, that gave the Utility, Manitoba Hydro, greater confidence that this project would come in close to $6.5 billion?

MR. DAVID BOWEN: I think, as discussed with the other projects here today, one (1) of the first risks of any major -- major project is getting -- securing pricing from contractors. At this point in time, the general civil contract, it's the largest risk on Keeyask. We had secured that price, and it gave us more confidence in the potential outcome.

MR. BOB PETERS: With the benefit of hindsight, we can say that that really didn't turn out the way it was expected correct?

MR. DAVID BOWEN: Yes. We're at 50 percent complete right now. Our control budgets increased from six point five (6.5) to eight point seven (8.7). We are doing everything we can to come in lower than that, and that's what we'll keep doing, But -- but yes, we look back over the last two (2) years, that's -- that's exactly right.

MR. BOB PETERS: Another one (1) of the concerns -- or lessons that was learned from the Wuskwatim project was that from the point in time in which the general service contractor had been engaged until the end of the project, costs increased between 10 and 13 percent on the Wuskwatim project, correct?

MR. DAVID BOWEN: Yes, it was in that ballpark.

MR. BOB PETERS: And back on page 31 of Board counsel's book of documents, the -- the suggestion then, Mr. Bowen, is because for Keeyask the general service contract had already been awarded, the cost increases that you saw in Wuskwatim after the general civil contract was awarded would lead you to believe that the risks would probably be less than 10 or 13 percent more for Keeyask?

MR. DAVID BOWEN: Correct. At that time, we -- we believe that -- that the risk represented here, and what we knew, we would be within our control or -- or much closer to control. But as you've already mentioned, is that hindsight is 20/20, and the -- the project has incurred a -- a substantial cost increase.

MR. BOB PETERS: And if we -- if we go back, Mr. Bowen, to page 11 and look at that waterfall in the MGF project services report, leaving aside the general civil contract, and I suppose the contingency, a lot of the other contracts fluctuated, but probably within the percentage range that you were expecting

after Wuskwatim. Would that be fair?
MR. DAVID BOWEN: The general civil contract drives the project -- the schedule for the work drives the project, so if we're on site longer, if we have more person hours and more people in camp for longer, generally all our costs go up because of running the -- operating the town of Keeyask, if you like. So -- so, yes, there's a knock-on effect, and -- and it's driven through being there longer and -- and more person hours driven by this work.
MR. BOB PETERS: All right. I -- I appreciate the clarification. What you're telling this panel is that because the general civil contract was the largest source of cost increase and delay in schedule increase, that had a -- an effect on many of the other items that are listed on page 11 in the -- the waterfall?
MR. DAVID BOWEN: That's right.
MR. BOB PETERS: All right. I've got your point. Thank you. Now for Wuskwatim, Mr. Bowen, do you recall if Manitoba Hydro included a labour reserve or an escalation reserve?
MR. DAVID BOWEN: I don't believe we had either for Wuskwatim.
MR. BOB PETERS: But you did have for

Keeyask, correct?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: And you had both a labour reserve and an escalation reserve?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: And as you've previously told me about ten (10) minutes ago, that labour reserve just turned out to not be large enough in -- in light of the productivity challenges that the project has faced?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: One (1) of the other mitigating factors that Manitoba Hydro was thinking would give a higher level of confidence was because it had a comprehensive schedule that linked the design, procurement, and construction together.

Do you recall that?

MR. DAVID BOWEN: Sorry, can you repeat the question?

MR. BOB PETERS: The essence of the question is that Manitoba Hydro had confidence in its Keeyask price because with Keeyask, it had a comprehensive schedule that linked design, procurement, and construction?

MR. DAVID BOWEN: Yes, we had a -- a

well-developed schedule that links all the different parts of the work together, and -- which is required for any of this work, and -- and the -- yes, it -- it's fundamental to carrying out any estimate and providing confidence in what you're doing.

MR. BOB PETERS: And Wuskwatim didn't have that, did it?

MR. DAVID BOWEN: I -- I didn't say that. Wuskwatim had a comprehensive schedule developed as well.

MR. BOB PETERS: To the same degree as Keeyask's?

MR. JEFF STRONGMAN: If you don't mind, I'll jump in on the Wuskwatim question.

MR. BOB PETERS: Absolutely, Mr. Strongman.

MR. JEFF STRONGMAN: Wuskwatim's schedule was not as well-developed as Keeyask. We certainly learned a lot in -- in the scheduling aspects of executing Wuskwatim, and we incorporated many of those lessons into what we're now doing for Keeyask. So the status of our Keeyask schedule is certainly an improvement upon what we had for Wuskwatim.

MR. BOB PETERS: Even though the

comprehensive schedule existed, Mr. Strongman, it -- it was such that it -- it hasn't been complied with such that a new schedule's had to be developed?

MR. JEFF STRONGMAN: Are you referring now to Keeyask?

MR. BOB PETERS: I was, yes.

MR. JEFF STRONGMAN: Yes. Well, I think referring to the BCG chart that I identified, the variance between plan versus actual concrete production, the order of magnitude of the variance was such that the schedule was very quickly no longer effective in managing the work in 2016.

MR. BOB PETERS: All right. You're referring back to pag -- page 7 of Board counsel's book of documents, and you're telling this Board at the bottom right-hand corner, there is a chart, and the performance on -- and the productivity on concrete got behind so much, so quickly, so early that Manitoba Hydro wasn't able to recover from that?

MR. JEFF STRONGMAN: Precisely.

MR. BOB PETERS: Now, with Keeyask in the general serv -- civil contract, Manitoba Hydro had a labour risk strategy that included a premier camp to attract and retain the craft labour, Mr. Bowen, and you talked about that with the -- with the panel after lunch today?

MR. DAVID BOWEN: That's correct.

MR. BOB PETERS: Was that labour risk related to productivity?

MR. DAVID BOWEN: I'll be more specific. The labour product -- productivity risk, it's about attraction and retention, so we wanted to provide a top-quality camp so people working away from home in a remote environment would -- would stay not only state our job, but come to our job. So, yes, that was part of our attraction and retention strategy, which is highly important for anyone whose care network and a remote project department anywhere in the world.

MR. BOB PETERS: Has the labour risk strategy been successful or unsuccessful with the hindsight?

MR. DAVID BOWEN: Some of it's been successful, and some of it hasn't.

MR. BOB PETERS: What part has not been successful?

MR. DAVID BOWEN: The part that hasn't been successful was that we are spending more person hours per unit of work than we originally planned.

MR. BOB PETERS: Mr. Bowen, on page 37

of Board counsel's book of documents, on the transcript from the Needs for and Alternatives to review, the Wuskwatim labour productivity was lower than expected, correct?

MR. JEFF STRONGMAN: The Wuskwatim labour productivity was definitely less than what was expected.

MR. BOB PETERS: And even with that knowledge, Mr. Strongman, the productivity rates in the Keeyask contract were greater than what was in the Wuskwatim arrangement?

MR. JEFF STRONGMAN: I -- I just want to caution it's -- for clarity purposes, it's actually misleading to say greater than or less than when -- man hours per cubic metre of concrete. As you spend more man hours per cubic metre of concrete, you're actually less productive. So just to try to help with that basic understanding.

MR. BOB PETERS: Thank you for -- I think you were correcting me. I thought I had said it actually correctly, but however many person hours are needed at Wuskwatim, even more person hours ended up being needed at Keeyask. Have I said that right?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: And even though

Manitoba Hydro knew that the person hours used at Wuskwatim weren't meeting the target, the target for Keeyask was for fewer person hours than it was at Wuskwatim, correct?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: Turning to page 40 of Board counsel's book of documents, this was a slide presentation made to Manitoba Hydro's Board of Directors. And I take it, Mr. Midford, you were probably a part of that? Or maybe Mr. Bowen, I don't know.

MR. LORNE MIDFORD: Sorry, what's the -- the date of this presentation?

(BRIEF PAUSE)

MR. BOB PETERS: We -- we're arguing over it. I think it's November of 2013. Does that help?

(BRIEF PAUSE)

MS. LOIS MORRISON: So, at that time, I wasn't -- I wasn't there at that time.

MR. BOB PETERS: Okay. Thank you,

sir. Let's not dwell on the date unless it's important to the witnesses, and -- and certainly, we'll -- we can try to track that down. But on this slide presentation, there's a contingency breakdown provided, and labour productivity is identified as a concern, but it's not included in the contingency. Have I -- have I got that right?

(BRIEF PAUSE)

MR. DAVID BOWEN: It doesn't appear to be here. I'd have to -- I -- I'd say yes, but subject to check.

MR. BOB PETERS: Okay. I'll accept that. Thank you, Mr. Bowen.

(BRIEF PAUSE)

MR. BOB PETERS: If we turn the page to page 41, a provision was added for Keeyask for a labour reserve as part of a management reserve, correct?

MR. DAVID BOWEN: Yes, that's correct.

(BRIEF PAUSE)

MR. BOB PETERS: So the labour productivity concern was not going to be addressed by the contingency, but it was going to be addressed by what is called a management reserve?

MR. DAVID BOWEN: Again, subject to check, I've been told by my colleague that this presentation was provided to our Hydro Board back in February of 2014. At that time, it clearly indicates that we're looking to -- may potentially have to access a labour reserve. I don't know whether or not contingency monies were allocated for labour at that time.

MR. BOB PETERS: Thank you.

(BRIEF PAUSE)

MR. BOB PETERS: Did Manitoba Hydro seek to get the productivity performance of the contractors that were constructing --

MS. HELGA VAN IDERSTINE: Mr. Peters, I just wanted to correct the date on that presentation. It appears to have been November 2013, so.

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: And -- and thank you, Ms. -- Ms. Van Iderstine. If we scroll ahead to page 59 of that same document, we see that there's a similar presentation using the same graphics made in February of 2014, correct?

MR. JEFF STRONGMAN: That appears to be correct, and that the timeline that we're referring to right now, it -- it proceeds involvement of each of the three (3) panelists in their current positions, just for clarification.

MR. BOB PETERS: Okay, thank you -- thank you very much. That's helpful, Mr. Strongman. And before Ms. Van Iderstine's point, I was asking the witnesses whether Manitoba Hydro contacted the general civil contractors constructing other Canadian Hydro dams to find out the productivity levels that were being achieved in the Canadian market?

(BRIEF PAUSE)

MR. JEFF STRONGMAN: Would you please repeat the question?

MR. BOB PETERS: Mr. Strongman, the -- I'm wondering if Manitoba Hydro, on receiving the productivity quotes from the general civil contractors, contacted any other Canadian utilities or Canadian general civil contractors working on programs of Hydro construction for their productivity rates.

MR. JEFF STRONGMAN: So yes, Manitoba Hydro is in -- in communication and collaboration with other Hydro utilities across Canada on a regular basis. Specifically referring to the time in question, I don't know specifically if the receipt of bids had prompted any communication, but certainly, we have tracking of project metrics across Canada from other utilities that would have served as a basis for comparison.

MR. BOB PETERS: Did any of those comparisons show as favourable as those bid by the BBE joint venture?

MR. JEFF STRONGMAN: So let me qualify my answer before making it. The information that we're getting into right now is -- is considered to be highly confidential, and each of the utilities across Canada that would have been a part of the communication would have taken steps to ensure protection of the information that would delve into a great level of detail. So, really, just high-level productivities would have been subject to discussion and -- and breakdowns or specifics would have been avoided at that time.

MR. BOB PETERS: All right. Thank you. I accept that, Mr. Strongman.

Mr. Bowen, one (1) of the other reasons that Manitoba Hydro gained confidence in the Keeyask project costs that were disclosed at the Needs for and Alternatives to review was because Manitoba Hydro had essentially locked down 80 percent of the contracts, correct?

MR. DAVID BOWEN: Yes, that's correct.

MR. BOB PETERS: And that really meant there was only 20 percent left to be tendered and to be awarded, and so that, Manitoba Hydro expected, would minimize the need for any increase in costs?

MR. DAVID BOWEN: As I spoke of earlier, one (1) of the major risks, again, is the tender of -- of contracts. And yes, we had got through our big ones at that time, and we were confident at that time.

MR. BOB PETERS: Manitoba Hydro for Keeyask also had a much better estimating process, would you accept that, than it did for Wuskwatim?

MR. DAVID BOWEN: I would -- I would say yes. We continued to improve, and -- and we continue to apply lessons learned and refine our --

our estimating process. So, yes.

MR. BOB PETERS: And another factor, Mr. Bowen, was that the regulatory review of the Wuskwatim project, that was conducted by the Clean Environment Commission, correct?

MR. DAVID BOWEN: I wasn't personally involved in that process, so I -- I believe that's correct, but I --

MR. BOB PETERS: And that -- that review happened -- Mr. Williams remembers that, but -- or at least his younger brother does. That Wuskwatim review happened much earlier, or actually years earlier, before the actual construction started compared to Keeyask, correct?

Ms. Mayor may be the one who has to assist on that.

(BRIEF PAUSE)

MS. HELGA VAN IDERSTINE: Yeah, we'd have to get back to you on that. I'm not sure that anybody's got that information at their -- at fingertips.

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: Thank you, Ms. Van Iderstine. I'm not going to ask for that as an undertaking, but the point I want to try to see if Mr. Bowen agrees, or Mr. Strongman agrees is for Wuskwatim, there was a lag between getting the regulatory approval and putting shovel in the ground.

Do you accept that as correct, that leg could have been several years?

MR. DAVID CORMIE: Mr. Peters, I was involved in this -- this process, and I -- your -- your premise is correct.

MR. BOB PETERS: And so, Mr. Bowen, with the Keeyask project, it looked like the ink was barely dry on the PUB's Needs for and Alternatives review before there was something being done in the river, the cofferdam was being constructed, correct?

MR. DAVID BOWEN: Our first -- our -- our start of construction in 2014 was pushing the first rock in the river, which happened on July 15th, which was very close to when the NFAT process closed.

MR. BOB PETERS: Within a matter of a few weeks after the Board's issued its -- its NFAT report?

MR. DAVID BOWEN: That's -- that's my recollection.

MR. BOB PETERS: All right. And Mr. Bowen, the whole point of going here is that gave Manitoba Hydro confidence that because of the relative duration between the regulatory approval and the actual construction, that, too, would serve to keep construction costs lower than they otherwise could be?

MR. DAVID BOWEN: Correct. I think -- I think what your -- point you're trying to make is that any delay to the construction would push back the contr -- the -- the project schedule, and there is a very large and significant cost for interest and escalation, and -- and yes, it would make it cost more.

MR. BOB PETERS: All right. Thank you, sir. Mr. Chair, if this suits the Board, this would be an appropriate time for an afternoon break.

THE CHAIRPERSON: Thank you. We'll break for fifteen (15) minutes.

--- Upon recessing at 2:47 p.m.
--- Upon resuming at 3:06 p.m.

THE CHAIRPERSON: Mr. Peters...?

MR. BOB PETERS: Thank you, sir.

MS. HELGA VAN IDERSTINE: May I just

jump in. We have -- at the outset of the hearing this afternoon Panel Member McKay had asked a question which seemed quite simple to answer and we're having a challenge with it, but it actually was a little more complicated, which is why we waited and now Mr. Strongman has the answer.

MR. JEFF STRONGMAN: So I believe the question was relating to the number of hours worked. So I've -- I've got the data handy to respond to the question.

The milestone that was celebrated back in June of 2017 of 2 million hours and 4 million hours for KCN employees and Indigenous employees respectively that, as I said, was the summertime. By year's end of 2017 the total KCN hours worked was 2.3 million and the total Indigenous hours worked in -- on the project by the end of 2017 was 5.8 million, on a total -- total labour hours worked of 15.3 million.

So the Indigenous proportion of the total was close to 40 percent, and the remark that I'd made previously was that this proportion is unprecedented in megaproject work within Canada.

I believe that was responsive to the question you'd asked.

THE CHAIRPERSON: Mr. Peters...?

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: Thank you. On slide 56 of Manitoba Hydro Exhibit 120, one (1) of the issues raised for the cost overruns related to geotechnical issues, correct?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: In one (1) of the reports that was obtained, it was in the MGF report specifically by the contractor KCB, Klohn Crippen Berger, they found that the quantities of earthworks and excavations were close to forecast.

Do you recall them saying that, Mr. Bowen or Mr. Strongman?

MR. JEFF STRONGMAN: Yes, I recall that. I think the comment was in relation to concrete work. They were remarkably close and on earthworks the net sum was very close with some expected deviation according to different classes of excavation.

MR. BOB PETERS: Your memory's better than mine. And on that note, then, Mr. Strongman, why did the geotechnical issues cause problems if, as KCB found, the quantities were very close to what was forecast?

MR. JEFF STRONGMAN: Good question.

In the slide deck that I presented earlier this morning, I attempted to lay the groundwork, if you done mine the pun, for the answer to that question. There's a couple of slides and one (1) of them made reference "to dinner plate clean." It's on slide deck number 17.

Do you see the pictures here? You can see on the left that the -- the undulations of the bedrock are quite substantial and as the people are standing in the high and low spots there's a variation of -- of a number of feet in this picture and many metres over a long stretch of -- of ground.

On the right side you can see a picture showing where rock material has been placed at the base and in the -- in the foreground of that shot where there has yet to be any material placed. And with such significant variation on the bedrock, one of the means of leveling the surface before preparing it for the high-volume machinery with higher productivity levels would be to add in what we call dental concrete. Dental concrete is a lien mix of concrete. It's -- it's less expensive than structural concrete. There's less cement there, but it's really used to fill up all the voids.

And our estimation of -- of how much

dental concrete was going to be required on this job was minimal and as the ground conditions have dictated, it's been one (1) of those concrete -- sorry, one (1) of those quantities where substantially more has been required to date.

MR. BOB PETERS: Can you quantify the dollar and schedule impacts from that dental concrete issue?

MR. JEFF STRONGMAN: The dental concrete issue itself, I can quantify saying that we assumed 1 or 2000 cubic metres of concrete and I think by the end of the second year we had already used at least 10,000 with two (2) more years of earthworks to go. I'd have to check to confirm those numbers, but those pop to mind.

The actual cost impact of that? I would hold back from quantifying because I don't have certainty on what the number is.

MR. BOB PETERS: But in term --

MR. JEFF STRONGMAN: Probably what is more significant is the impact to the overall productivity of having to spend considerably more time getting off the rock -- sorry, is that better?

(BRIEF PAUSE)

MR. JEFF STRONGMAN: So I tried to quantify the -- the volumes. I'm not sure if that was well understood. In any event, the -- the impact from volume and costs is substantial but probably even more impactful is the schedule delay associated with taking considerably more time than planned to clean the surface of the rock to ensure that the base of the earth structures are well founded, and that there is no potential water path or seepage path once the impoundment takes place.

MR. BOB PETERS: While you haven't put a dollar value on the record, Mr. Strongman, by how many weeks, months was the project delayed because of difficulty in getting this dental concrete in place?

MR. JEFF STRONGMAN: It's a good question. Before being able to answer the question, there needs to be an understanding that there is multiple parallel paths of critical work happening. So the earthworks that's taking place, if we just talk about earthworks in exclusivity, we would be measuring the delay experience from getting off the rock in a number of months. On the North dam, for instance, which is nearing completion, we might have spent three (3) to six (6) months longer than planned in preparing the base before we could work up.

The central dam which is approximately a third completed, we would've had a similar impact there.

And for the south dam which has yet to be constructed because that's currently the path of the -- the river and won't be constructed until, at the very earliest, after next year, there's no measurable delay there yet.

Now, as the earthworks are proceeding we're also building concrete works and concrete has had its own different challenges. So saying what the effect of this earthworks issue has to the overall project schedule, it's happening at the same time as -- as we're experiencing some delays on concrete. So it's -- it's hard to be specific about exactly what that number is.

MR. BOB PETERS: Is Manitoba Hydro attributing any of the delay in the schedule to the dental concrete?

MR. DAVID BOWEN: If I could just add to Mr. Strongman's comments, the -- the concrete works right now is driving the schedule, the critical path. So -- so right now the earthworks is a shorter duration and -- and we should not be waiting for the earthworks structures to water up and -- and to energize our -- our units.

So if that assumption holds true for the remainder, then the earthworks will not delay our critical path because the concrete path is longer.

MR. BOB PETERS: Were the cost increases addressed for this dental concrete in the original contingency amount set aside for the original general civil contract?

MR. DAVID BOWEN: I would say that, no, there's been a lot more dental concrete work that's been performed than originally anticipated.

MR. BOB PETERS: So that answer really means, Mr. Bowen, that the original contingency amount was insufficient for this -- for this problem?

MR. DAVID BOWEN: Correct. The -- the undulations shown here, I believe that some of the Panel members, when you -- they came to site this past summer on the central dan, we -- there was a -- a pretty significant fault that was right in the middle of the central dam where we've had to go around that -- those conditions to the act -- that -- to that extent weren't anticipated and -- and -- and they're costing more than we originally anticipated.

MR. BOB PETERS: All right. Let's

move us along the timeline, gentlemen, that before the end of the 2016 construction season Manitoba Hydro's management and Board of Directors had concerns about the -- the productivity at Keeyask; that's correct?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: And we know that Manitoba Hydro engaged KPMG in May approximately of 2016 to help address some of the problems; correct?

MR. JEFF STRONGMAN: That's correct. The KPMG engagement was self-directed assessment of the Keeyask project's systems and processes to identify opportunities for improvement and then act on those recommendations.

MR. BOB PETERS: And in mid to late 2016 -- 2016, the Manitoba Hydro Board of Directors made a decision to proceed with both Bipole III and Keeyask?

MR. LORNE MIDFORD: Yes, that's right.

MR. BOB PETERS: And that was after Manitoba Hydro's Board of Directors considered whether they should cancel construction on both of those megaprojects; correct?

MR. LORNE MIDFORD: Yes.

MR. BOB PETERS: And moving forward, Manitoba Hydro developed the BBE recovery roadmap in late 2016; is that also correct, Mr. Midford?

MR. LORNE MIDFORD: Yes, that's -- that's correct.

MR. BOB PETERS: And then as a result of that recovery roadmap, a recovery plan was prepared by Manitoba Hydro in late 2016 or early 2017?

MR. LORNE MIDFORD: Yes, that's -- that's accurate.

MR. BOB PETERS: And I understand from previous answers that the consulting firm KPMG, who's provided a letter as appendix A to Manitoba Hydro's rebuttal, KPMG provided the services to help with that recovery plan?

MR. DAVID BOWEN: That's right.

MR. BOB PETERS: Is KPMG still providing services on Keeyask?

MR. DAVID BOWEN: Yes, they are.

MR. BOB PETERS: Can you tell the Board briefly what KPMG is doing?

MR. DAVID BOWEN: KPMG's providing advisory services to the pro -- to project management for the construction of Keeyask and so much like Mr. Peters has just stated, they were heavily involved with the recovery plan, which began initiated back in September 2016, but they're providing ongoing support to our team for various issues as they arise on the -- on the construction.

MR. BOB PETERS: Did KPMG also assist on the assessment of the Bipole III project?

MR. ALISTAIR FOGG: Sorry, Mr. Peters, in terms of the Bipole III project from the proceed or not proceed perspective or...?

MR. BOB PETERS: Mr. Fogg, I understand that KPMG was engaged on approximately May the 2nd, 2016. Can you accept that as accurate?

MR. ALISTAIR FOGG: For Keeyask or for -- for Bipole III?

MR. BOB PETERS: No, for the engagement of KPMG engagement entirely. And maybe what I could do is I could ask Diana to find Manitoba Hydro's rebuttal evidence and we'll turn to I guess 59 might be the first page of the -- it might be a KPMG letter. No. If we follow page 58 of 58, a couple more pages ahead, Diana, please. All right, thank you.

(BRIEF PAUSE)

MR. BOB PETERS: This is what I was thinking of is that KPMG was engaged by Hydro on May the 2nd and they provided a review of the Keeyask generating station project and they talked about development and implementation of a recovery plan, correct? Mr. Strongman or Mr. Midford?

MR. LORNE MIDFORD: Yes, that's correct.

MR. BOB PETERS: My question then, Mr. Fogg, was: Did KPMG also have any role to play since May the 2nd, 2016, in respect to Bipole III?

MR. ALISTAIR FOGG: KPMG has not have -- had an active role on Bipole since May 2nd; earlier to that they were involved on Bipole III conducting, I believe the term has come up, for a health check on the project processes and services.

MR. BOB PETERS: Are these -- Mr. Fogg, was this an extensive health check? Is this an annual medical or is this just a walk-in clinic view?

MR. ALISTAIR FOGG: I wouldn't context it as a trip to the ER necessarily. It was a thorough review of our processes and standards for Bipole III and with some areas of recommendations for improvement.

MR. BOB PETERS: All right. Perhaps the better way for the Board to assess the duration and the scope of their involvement, Mr. Midford, could you undertake to provide the Board with an indication of how much Manitoba Hydro has paid KPMG since May the 2nd on the Keeyask project and, likewise, how much they've paid KPMG related to the Bipole III project?

MS. HELGA VAN IDERSTINE: We'll take that under advisement, Mr. Peters.

MR. BOB PETERS: All right, thank you.

--- UNDERTAKING NO. 56: Manitoba Hydro to provide the Board with an indication of how much Manitoba Hydro has paid KPMG since May the 2nd on the Keeyask project and, likewise, how much they've paid KPMG related to the Bipole III project. (TAKEN UNDER ADVISEMENT)

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: Any costs of these third-party consultants would be included in the control budget; is that correct, Mr. Midford?

MR. LORNE MIDFORD: Yes, that's right.

MR. BOB PETERS: Thank you. In this

process, Mr. Midford, did Manitoba Hydro management consider the cost to walk away from the Keeyask project, in essence, shut it down?

MR. LORNE MIDFORD: I'm not sure what you're -- are you referring to the KPMG engagement or the BCG from the Board? Sorry.

MR. BOB PETERS: Let me rephrase the question. During this review process and just prior to preparing the recovery roadmap and the recovery plan, Manitoba Hydro, as I understood the evidence of your president, had considered on a couple of occasions whether to stop construction on Keeyask entirely; correct?

MR. LORNE MIDFORD: The Manitoba Hydro Board hired BCG in, as you know, in '16 to -- to review the projects and -- and provide that recommendation to them in terms of the -- the economics of continuing or looking at other alternatives going forward. And so that was the main focus of the BCG review. So that was provided to the Manitoba Hydro Board towards the end of '16, I believe.

Since then, internally we've done a refresh of that review which I think was provided in earlier testimony with the new control budget of the

$8.7 billion. And so -- so I believe what our CEO was referring to was the refresh of that analysis in the spring of 2017 by Manitoba -- internally by Manitoba Hydro staff.

MR. BOB PETERS: Has Manitoba Hydro calculated what the cost of stopping work on Keeyask would be and what it would mean for ratepayers?

MR. LORNE MIDFORD: Sorry, Mr. Peters, can you just repeat that.

MR. BOB PETERS: I'm wondering, Mr. Midford, whether Manitoba Hydro had calculated the cost of discontinuing work on Keeyask, together with any ratepayer impacts that might have?

MR. LORNE MIDFORD: Yes, I believe that was done.

MR. BOB PETERS: And are those -- is that information something that Manitoba Hydro can provide to this Board on the public record?

MS. HELGA VAN IDERSTINE: I think -- I think we -- yeah, I don't think the detail of that has been provided, Mr. Peters. It was provided at a high level I think, in -- either in an MFR or an IR, so, we'd have to check into that and whether that's determ -- we can provide more detail.

MR. BOB PETERS: All right, if you

could undertake then, Ms. Van Iderstine, to advise the Panel of Manitoba Hydro's calculation of the costs for stopping construction on Keeyask entirely, together with what, if any, rate impacts that would have.

That would be appreciated.

MS. HELGA VAN IDERSTINE: Excuse me, if that -- if that's been done then I -- we'll look into it and if it's possible to produce it, we will. But I'm not entirely certain it's been done in that entire -- in that detail.

MR. BOB PETERS: Thank you.

--- UNDERTAKING NO. 57: To advise the Panel of Manitoba Hydro's calculation of the costs for stopping construction on Keeyask entirely, together with what, if any, rate impacts that would have.

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: In terms of Manitoba Hydro's recovery roadmap, one (1) of the options to go forward was to start with a new general civil contractor; is that correct?

MR. DAVID BOWEN: That -- that's what's shown there, yes, on slide 57 of my presentation this morning.

(BRIEF PAUSE)

MR. BOB PETERS: Is it correct for this Board to understand, Mr. Bowen, that when Manitoba Hydro was developing the recovery roadmap, the general civil contractor that we've called BBE was not interested in continuing under the old contract?

MR. DAVID BOWEN: I'd like to provide the most complete answer today, but I would request that be able to provide more information tomorrow. Certainly BBE was aware of the challenges they were having and, certainly, they wanted to do everything they could to -- to help Manitoba Hydro and continue with the project.

MR. BOB PETERS: But it's a matter of public record, is it, Mr. Bowen, that one (1) of the options considered by Manitoba Hydro was to part company with BBE and proceed in a different direction?

MR. DAVID BOWEN: Yes, that's what's shown on slide 57.

MR. BOB PETERS: The other option would be to reduce the scope of work for BBE and bring in some additional contractors to help?

MR. DAVID BOWEN: We -- we considered descoping, yes.

MR. BOB PETERS: And descoping for those of us who aren't all that familiar with the word really means, put a new contract together with BBE but also bring in somebody else to do some of the work that BBE wasn't given in the new contract?

MR. DAVID BOWEN: More -- more or less, it would -- it would change the scope of work they had and would bring in different parties to execute portions of that work.

(BRIEF PAUSE)

MR. BOB PETERS: Let's jumped to when Manitoba Hydro decided to continue the relationship with BBE as the general civil contractor, Mr. Bowen; that meant Manitoba Hydro had to, in essence, renegotiate with them to continue?

MS. HELGA VAN IDERSTINE: Excuse me, Mr. Peters, I just --

MR. BOB PETERS: I'm sorry.

MS. HELGA VAN IDERSTINE: -- wanted to have a quick chat with -- with Mr. Bowen. I -- I know he's concerned at this point to some of the questions are getting quite close to things that he'd be concerned about relating -- that affect the relationship with some of the parties and would otherwise be CSI so.

We want to be as open as we can in this process so that the public is aware of what's going on and response of -- it's getting too close.

MR. BOB PETERS: Since that, Ms. Van Iderstine, and I move to a new topic if -- if that permit -- but if I am encroaching and that sensitivity arises again, please, don't hesitate to -- to let us know.

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: I wanted to turn, Mr. Bowen, to Manitoba Hydro having made the decision to continue with BBE as the general civil contractor; that meant that there had to be a new negotiation with that contractor; correct?

MR. DAVID BOWEN: Correct, based on the -- the challenge we had and -- and the problems that, yes, we need to negotiate a new path forward.

MR. BOB PETERS: And I'll put the question out and you'll tell me if I'm getting too close to the line, but under the original contract the cost overruns due to the productivity problems had a negative impact on BBE's profits?

MR. DAVID BOWEN: I'd like to discuss that tomorrow --

MR. BOB PETERS: All right.

MR. DAVID BOWEN: -- if I may.

DR. BYRON WILLIAMS: Mr. -- Mr. Chair, just -- Byron Williams for the Consumers Coalition. I'll just note that if one goes to the KPMG letter attached to Manitoba Hydro's rebuttal evidence, there's a fair bit of information in there and -- and certainly our client always is interested in as much information on the public domain as possible.

I'm not as confident as Manitoba Hydro that we are coming close to -- close to that line. This is important public information.

THE CHAIRPERSON: Thank you, Dr. Williams, and -- and I'm sure that in your cross-examination, if it's on the record already, you may go to it.

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: Mr. Bowen, in late 2016 or early 2017 both Hydro and BBE signed what is known as Amending Agreement Number 7?

MR. DAVID BOWEN: Yes, that occur -- occurred in early 2017.

MR. BOB PETERS: And essentially, that's the new general civil contract going forward and that's the one that's in place today?

MR. DAVID BOWEN: Correct, that agreement amended the existing original contract.

MR. BOB PETERS: And under this Amending Agreement 7, there was a recalibration of the productivity required from BBE and the profit to be allowed to BBE?

MR. DAVID BOWEN: That's correct.

MR. BOB PETERS: And there was a new target price for the completed contract?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: And there was a new profit amount determined that would be available to BBE?

MR. DAVID BOWEN: Correct.

MR. BOB PETERS: Can you indicate whether BBE would also receive overheads and general

administrative cost allowance?
MR. DAVID BOWEN: Yes, general administration, overhead applied.
MR. BOB PETERS: Would be fair for this panel to understand, Mr. Bowen, that the new contract with BBE looked a lot like the old contract?
MR. DAVID BOWEN: Well, certainly, the -- the technical scope and the scope of work was -- was mostly unchanged. The commercial points of it, though, there are some pretty substantive changes.
MR. BOB PETERS: And those are the points you're going to tell the Panel about tomorrow?
MR. DAVID BOWEN: Yes.

(BRIEF PAUSE)

MR. BOB PETERS: All right. Are you able to tell the Board today, Mr. Bowen, that in addition to any contingency reserve in the Amending Agreement 7 whether there are management reserves?
MR. DAVID BOWEN: As I noted in my presentation, there were no management reserves contained in the control budget.
MR. BOB PETERS: Can you indicate why that's the case?

MR. DAVID BOWEN: I -- I tried to articulate that earlier. The -- the reason for -- management reserves are low probability/high-impact events and one (1) event could be if there was a major safety incident that, basically, stopped work in the powerhouse complex for months on end, which would have a direct impact on the scheduled date completion, of course, lots of costs.

At this point in the contract, in the project, we chose not to -- to choose these events to -- to put in the budget because of their large dollar value and -- and the low likelihood of occurrence.

MR. BOB PETERS: Keeping it at a high level, Mr. Bowen, we can fast-forward to the MGF services report in these proceedings, and there is an extract on page 43 of Board counsels' book of documents and MGF -- I'm sorry, I suggested it was a report, it's actually in response to an Information Request.

MGF indicates that the Amending Agreement Number 7 is not being performed at an acceptable level. And as an example, more money is being spent for less process -- progress and revised productivities in Amending Agreement Number 7 are not being met.

Do you see that?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: Is that factually accurate?

MR. DAVID BOWEN: In -- in my presentation today, we talked about the -- the quantity deficits for both concrete and earthworks. So if we go back to the -- remind everyone of that conversation is that, we saw improvements to concrete production and to earthworks, but we had a deficit of 20 percent in the concrete and 25 percent in the earthworks.

The -- the work on the concrete, the -- the costs are higher than the amending agreement right now, and certainly we've seen some cost growth in other areas of the contract. So, those are some challenges that we're actively working on with our general civil contract as we speak to -- to bring those costs back in line with -- and improve upon them based on what was signed in the amending agreement.

MR. BOB PETERS: And so with that answer, Mr. Bowen, you're acknowledging as said by MGF that revised productivities in Amending Agreement Number 7 are not being met; correct?

MR. DAVID BOWEN: I'm -- I'm

qualifying the answer. In earthworks this year, we -- we saw an improvement overall. In -- in concrete we did see an improvement. I would -- I would characterize that improvement as a 20 percent improvement overall but if you look at the person hours, the dollars per person, yes, it's cost more than the -- than the amending agreement, but there is a complexity factor to consider as well.

MR. BOB PETERS: All right, thank you. And to complete the Keeyask cost estimates that are on the public record, MGF on page 45 of Board counsels' book of documents indicates that the order of magnitude estimate range to complete Keeyask, according to MGF, is between 9.5 billion and 10.5 billion.

You see that, sir?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: And Manitoba Hydro understands that the $9.5 billion number from MGF is if MGF -- is if Manitoba Hydro takes some mitigation steps that MGF has indicated are needed in the MGF report?

MR. DAVID BOWEN: The first thing I'm always concerned about, various consultants throwing out range of values. I think we've seen a history of that on the Keeyask project to date. We --we've -- we've provided -- Manitoba Hydro's provided our best estimate of where the project could end up. Certainly others can have other opinions and -- but it's -- it's -- it's challenging and dangerous to make opinions based on limited knowledge.

MR. BOB PETERS: I'll take that as a polite way of Manitoba Hydro disagreeing with MGF's view and you provided your written reasons in Manitoba Hydro's rebuttal, Mr. Bowen?

MR. DAVID CORMIE: Well, to be clear, the -- the P90 value for Manitoba Hydro's control budget was 9.6 billion which is in the range. We -- we did look at reserves with our budget and -- and certainly we're not disputing that we can -- the project has risks that could put us in this range. So I'm not disputing that fact, but I -- I don't -- we have difficulty understanding how MGF arrived at these numbers.

MR. BOB PETERS: All right, I have your point. Thank you. Now, you've already in your last few answers repeated what we heard in your presentation to the effect that more concrete was placed in 2017 than in 2016 and, likewise, more earthworks were completed in 2017 and 2016, correct?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: And you'll agree with me that -- and I think your answer may have contained the germ of the point I'm getting to -- is that just because more quantity of concrete and earth was placed in the prior years that doesn't mean Manitoba Hydro and BBE were more productive than in 2016; does it?

MR. DAVID BOWEN: To be clear, we saw a productivity improvement on the earthworks. The -- the earthworks is very easy to measure. For the concrete, the concrete work this year if we go back to the slides that Mr. Strongman showed of the work completed in 2016 compared to 2017. In 2016 we were metres off the ground. Whereas in 2017, we were tens of metres and lots of work was accessed by scaffolding. So it -- the work was higher, more -- more complex. The formwork we saw the draft to forms and we saw the top of the scroll case, all that formwork surround -- circular formwork compared to flat formwork.

So the complexity of the work, what I was trying to illustrate was the complexity of the work in 2017 was a fair bit more complex than in 2016. So overall, the productivity values, the dollar -- the person hours per unit to work, it did cost more, but when you weigh it with the complexity factor, there was certainly improvements that were made.

MR. BOB PETERS: Even with those improvements, Mr. Bowen, 2017 productivity for both concrete and earthworks were below the targets in the 2017 Amending Agreement Number 7?

MR. DAVID BOWEN: So I'll just -- I'll just correct the language for the -- for the record. The production targets which means the total volume of work completed were both less for concrete and earthworks and that was a 20 percent deficit for concrete and a 25 percent deficit for earthworks.

MR. BOB PETERS: From a productivity perspective, Mr. Bowen, was both the productivity for concrete and earthworks below target levels set in Amending Agreement Number 7?

MR. DAVID BOWEN: The earthworks improved and the concrete eroded based on the complexity factor I noted.

MR. BOB PETERS: And the complexity factor you note, and this is a non-engineering explanation, but you're telling the Panel that it was harder to pour the concrete in 2017 than it was in 2016?

MR. DAVID BOWEN: I'll try not to be

too much of an engineer. If you imagine each concrete placement, basically, you're putting up a wood box. You're putting in rebar. You're putting in a -- a water stop to prevent water from leaking through the dam. You're putting in a bunch of pipe, mechanical pipe. That whole cycle from starting with forming to actually placing the concrete in there and letting it harden, that's a whole cycle. So -- so, yes, that whole cycle was more challenging in 2017.

MR. BOB PETERS: Mr. Bowen, if productivity continued exactly going forward as it did in 2017 for both concrete and earthworks, does it mean that the MGF cost estimate is a possible result?

MR. DAVID BOWEN: We require a 10 percent improvement in our productivity for GCC and no major risk materialized to reach our control budget. If we saw a 0 percent increase, so just straight line, it would -- it would push us north of $9 billion and -- and would push us closer to the bottom of the MGF range.

MR. BOB PETERS: That 10 percent increase by the general civil contractor was for both concrete and earthworks?

MR. DAVID BOWEN: The -- the 10 percent improvement's required across the board. So I would characterize it as improving the productivity so the person hours per unit of work improving the production, so getting more volume of work, and improving the costs. So overall, the costs come down by 10 percent.

MR. BOB PETERS: And there's no management reserve for productivity in Amending Agreement Number 7, is there, Mr. Bowen?

MR. DAVID BOWEN: No, no, as I noted earlier, the -- there's no management reserve in our control budget and there is no management reserve in the amending agreement with the general civil contractor.

MR. BOB PETERS: So a lack of productivity drives up the cost just like it did when Manitoba Hydro had to go from the original BBE contract to the Amending Agreement Number 7?

MR. DAVID BOWEN: Certainly, the -- the productivity rate will dictate whether the costs goes up or down for -- for this work, yes.

And -- and as I noted earlier, we have a number of mitigation plans in place with BBE, our contractor, and Manitoba Hydro to improve upon those results and drive down the costs.

MR. BOB PETERS: Let's turn, if we

could, to discuss the types of contracts in a bit more detail. Starting on page 54 of Board counsels' book of documents, we have an extract from the MGF report. I don't know if it's a colloquialism or something, but it -- in construction time is money. In traditional fixed contracts time is the contractor's money and in cost reimbursable contracts, time is the owner's money.

Do you see that, Mr. Bowen?

MR. DAVID BOWEN: Yes.

MR. BOB PETERS: Have you heard that before?

MR. DAVID BOWEN: Yes, I've heard it from a few engineers in the past.

MR. BOB PETERS: Is it true?

MR. DAVID BOWEN: It's in there -- it's a very narrow view. Certainly at face value, yes, it's absolutely true. In the context it's presented, the -- we do not have a cost reimbursable contract. We have a target price contract and so I -- I think in the context it's presented that it's -- it's misleading.

MR. BOB PETERS: Okay, let's -- let's go there. In terms of which of those three (3) most closely aligns or which -- sorry, which of those two

(2), the fixed contract or the cost reimbursable aligns with Hydro's original contract with BBE. Most closely, it would be the cost reimbursable contract; would you accept that?

MR. DAVID BOWEN: I'd say it's somewhere in between --

MR. BOB PETERS: All right and what about --

MR. DAVID BOWEN: -- the fixed --

MR. BOB PETERS: -- the Amending Agreement Number 7, is that closer to a cost reimbursable contract --

MR. DAVID BOWEN: Yes --

MR. BOB PETERS: -- than a fixed contract?

MR. DAVID BOWEN: Pardon me, it's -- it's somewhere in between.

MR. BOB PETERS: Would you be more comfortable, Mr. Bowen, if Manitoba Hydro's contract was called a cost reimbursable contract with a target price?

MR. DAVID BOWEN: Yes, that's indeed what it's called.

MR. BOB PETERS: On page 55 of Board counsels' book of documents, there are some slides that were presented at one (1) of the meetings with Manitoba Hydro's Board of Directors.

So, Mr. Midford, if you saw it it was probably this February 14th version. Have you seen it before?

MR. LORNE MIDFORD: Yes.

MR. BOB PETERS: All right. So let's -- subject to anybody checking, and I'm not sure it matters, but this was a presentation made to the Manitoba Hydro Electric Board of Directors; correct?

MR. LORNE MIDFORD: That's my understanding.

MR. BOB PETERS: All right, did anybody on this panel present it to the Board of Directors? I'm seeing shaking heads so --

MR. LORNE MIDFORD: No.

MR. BOB PETERS: All right. I'd like to move quickly through it, but I want the panel, the witness panel, to explain to the Board Panel exactly how a cost reimbursable contract with a target price works. So we start on page 55.

And on this chart, the actual cost of work is on the bottom axis and what the contractor is paid is cont -- is identified on the vertical axis, correct?

MR. JEFF STRONGMAN: I'll attempt to answer your questions in this region.

MR. BOB PETERS: All right.

MR. JEFF STRONGMAN: However, having said that, I'm -- I'm not familiar with the references to these charts. But certainly I can explain the contract model.

MR. BOB PETERS: And that's -- that's really what I want to do is explain it with these documents, if I could, Mr. Strongman --

MR. JEFF STRONGMAN: Okay.

MR. BOB PETERS: -- and to the extent you can help. So on page 55, we start off, there's the initials TP or -- that stands for Target Price up at the top of the chart?

MR. JEFF STRONGMAN: Agree.

MR. BOB PETERS: And that's Manitoba Hydro's target price that would intercept the horizontal access at some dollar value, correct?

MR. JEFF STRONGMAN: Correct.

MR. BOB PETERS: And we knew that that dollar value was $6.5 billion when the first contract was -- was let.

MR. JEFF STRONGMAN: Just to be clear, the -- the project budget was 6.5 billion, but the contract value would have been considerably less than that, given it was a component of the overall project.

MR. BOB PETERS: All right, I perhaps didn't word the question properly.

What you're telling the Panel is the general civil contract is only a portion of the total $6.5 billion total price?

MR. JEFF STRONGMAN: That's right, in my earlier presentation, I think I said there was two hundred and thirty-nine (239) contracts awarded; of those, the general civil contract is the largest and it is the form of contract that we're currently discussing.

MR. BOB PETERS: All right, on page 6 -- 56 of Board counsels' book of documents, we progress along a time continuum here and we see that the contractor has been paid their actual cost of work, correct?

MR. JEFF STRONGMAN: Page 56 we're just presuming some hypothetical cost of work component?

MR. BOB PETERS: Yes, we are.

MR. JEFF STRONGMAN: Yep.

MR. BOB PETERS: And so you're agreeing that the contractor has been paid their cost of work?

MR. JEFF STRONGMAN: Yes.

MR. BOB PETERS: That's the actual cost that the contractor would charge to Manitoba Hydro, if this applied to Manitoba Hydro?

MR. JEFF STRONGMAN: Yes, this theoretical example appears to be so.

MR. BOB PETERS: It's not tied to a unit or a -- or a fixed price, it's based on what the actual cost is by the contractor?

MR. JEFF STRONGMAN: But the actual cost of the work that complies with the cost reimbursable requirements within the contract.

MR. BOB PETERS: What you're telling the Panel is there's a maximum amount this contractor's going to receive under a cost reimbursable contract with a target price. But until that -- that target price is met, the contractor is going to be paid their actual cost of doing work?

MR. JEFF STRONGMAN: That's right.

MR. BOB PETERS: So maybe let me try it this way and let's bring it back to Keeyask. We've heard of evid -- excuse me, we've heard evidence that the contractor was not meeting the productivity levels in the placement of concrete; correct, Mr. Strongman?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: Even though the contractor wasn't meeting those productivity levels, that means the contractor was actually taking longer to do what they were supposed to be doing?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: And by the contractor taking longer to do work, the contractor was getting paid more because that was their actual cost of work?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: So even though the contractor was -- had a productivity target, they weren't meeting it, they were still getting paid for their actual cost of work?

MR. JEFF STRONGMAN: Yes.

MR. BOB PETERS: And on top of being paid for their actual cost of work, the contractor was also getting a separate cheque representing their profit?

MR. JEFF STRONGMAN: The provisions within the contract specify the general administrative and overhead expenses that are a potential markup on top of the cost, subject to limitations, as well as a profit percentage that would be a markup on top of the actual cost of the work, subject to a separate range of limitations.

MR. BOB PETERS: All right, and that's what this is showing on page 56 is that the actual cost to work being done is being reimbursed to the contractor and the contractor's getting on top of that some profit and what's not shown is the overheads and general administration costs?

MR. JEFF STRONGMAN: Yes.

MR. BOB PETERS: And so now on page 57, there is a continuing actual cost of work being done by the -- by the contractor and while the contractor is doing more work, they're still being paid the same as they were on the slide 56?

Mr. Strongman, that's your understanding?

MR. JEFF STRONGMAN: One moment please.

(BRIEF PAUSE)

MR. JEFF STRONGMAN: Mr. Peters, if -- if you don't mind, I'll take a crack at explaining the basics of the contract without making specific reference to the charts because I find them less than clear in terms of the questions that you're asking me.

I think I can give you the information that you're seeking if you don't mind. Okay.

MR. BOB PETERS: Let's try.

MR. JEFF STRONGMAN: In a cost reimbursable target price contract, Mr. Peters, was explaining that the contractor is reimbursed for costs incurred to do the work.

How the target price comes into play is the contractor's bid for all the different units of work and the quantities to be performed times the prices that he submitted as his estimate to do the work creates an extension of all the line items, fifty (50) or sixty (60) odd different line items times the prices that he's quoted and that becomes the target price.

So if we just assigned a number to it, let's say, it's $100. Through the execution of the work, the contractors entering monthly invoices of one (1) or two (2) or three dollars ($3) a month all the time performing work and being reimbursed for those costs.

We're constantly comparing the unit costs that the contractor's engaging in and comparing those to what the bid price was to understand long before we're at the end of the job whether or not there is a positive variance happening, a negative variance or they're on track.

So, if the contractor's work is happening and it's costing more expensive than what their bid price is, we are obligated to reimburse them according to the terms of the contract but we're very quickly tracking the fact that we're seeing a variance take place and should things continue to the end, there would be a projection of an overrun and, therefore, the provisions of the contract would indicate that the contractor's expected profit would be eroded by that overrun.

Our contract says that for every dollar overrun we experience the contractor's cost beyond the target price, their profit would be eroded by eighty cents ($0.80) on the dollar. Conversely, if they proceed to spend and incur less cost to complete the work, and they end up saving us money, then Manitoba Hydro pays less for the work to be accomplished, and we also share in the savings with the contractor. So we give them, in effect, an incentive to reduce cost and -- and perform better than planned.

I think what Mr. Peters is driving at is through the course of execution of the work, the contractor is reimbursed for the cost. They also have their markup for general admin, and overhead, and profit, and that all works out fine unless you start seeing a variance. And then you account for that variance by either triggering the general admin and overhead provisions that cap, or a profit erosion looks to be probable, and then you start modifying how the profit would be paid. And there's a reconciliation at the end of the job on the assumption that those are all close.

In our case, through 2016, the variance between plan and actual was so significant, we didn't need to wait to the end of the job to know that the variance was causing a problem on simply executing the work. And that triggered many of the recovery plans, and development and implementation of the recovery, and -- and negotiation of the contract terms that we've been describing today.

How was that, Mr. Peters?

MR. BOB PETERS: That was, I'll say, excellent and I appreciate that. So to help the Board understand your -- your latter comments on Tab 60 of the Board counsel -- or page 60 of Board counsel book of documents. And if this is -- this is an example where there's a cost underrun, and if you're not comfortable, Mr. Strongman, answering it, I don't want you to go there, but in an example of a cost underrun between the actual cost of work done and the target price, there's a sharing of the surplus monies, correct?

MR. JEFF STRONGMAN: Yes. If we use the hundred dollar job cost, that I threw out there, if the contractor's cost of doing the work is only ninety (90) at the finish and they, therefore, save ten (10), Manitoba Hydro would keep eight (8) of that ten (10), and give the contractor two (2) of it as an incentive for beating the target price on the work.

MR. BOB PETERS: So let's take that, Mr. Strongman, and let's go to page 61, in an example where there's a cost overrun. And how does that work under this cost reimbursable arrangement with the target price?

MR. JEFF STRONGMAN: Okay. So if we had the same hundred dollar target price, but this time, the actual cost of the work exceeds, and it costs us a hundred and ten (110), Manitoba Hydro has paid the hundred and ten (110) as an incurring cost to do the work, but the contractor's profit will be eroded at a rate of 80 percent of that ten dollar ($10) overrun, such that Manitoba Hydro is effectively clawing back cost of work payments that have already been made but to reconcile on the profit to ensure that the terms of the contract relating to profit are fulfilled. That would probably be done at the end of the project, but we're still talking in a hypothetical.

MR. BOB PETERS: All right. And while the contractor would bear the pain of that 80 percent of the cost overrun, Manitoba Hydro would bear the other 20 percent of that pain?

MR. JEFF STRONGMAN: That's right. So when we paid out a hundred and ten (110) to get the work done, we would then recover eight (8) out of the ten dollar ($10) overrun by removing that from the contractor's profit entitlement. We would still be out a couple dollars beyond the hundred dollar project budget, because that was our 20 percent that we own from the contract term.

MR. BOB PETERS: All right. And the example I -- I want to turn to is on page 62. And in the situation in which the actual cost of work exceeds the target price and also exceeds the profit that was to be paid to the contractor, what happens in that instance?

MR. JEFF STRONGMAN: Okay. Well, this is the scenario that most closely relates to Keeyask in 2016 prior to amending agreement number 7. However, just to qualify that comment, we were basing on a projection because we were nowhere near the end of the job, but the job was projecting to be in the situation that is described here on page 62, where actual cost of the work exceeded the target price as well as the limitation of liability from the contractor's profit.

So in other words, the job costs were going to be so far beyond the plan that even after clawing back the contractor's profit, we would still be incurring costs that we had no recourse for.

MR. BOB PETERS: Could you repeat that last -- last response? You'd be clawing back --

MR. JEFF STRONGMAN: We would be recovering a portion of the costs from the contractor's exposure to liability by reducing their profit, but -- and once that profit was fully recovered, the contractor's limit of liability is no more. We have no recourse to penalize or effectively recover any costs. We were on the -- on the hook for the 100 percent of the costs beyond the contractor's profit. It's a scenario that clearly, we did not envision and see as a -- a likely outcome. However, we found ourselves there.

MR. BOB PETERS: Mr. Strongman, we saw in Manitoba Hydro's slides that contracts for things like -- I think it was the -- the turbines and generators were a fixed-price contract. Are you aware of that?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: But even if there's a fixed-price contract, that may end up costing Manitoba Hydro more money if the project is delayed, as I understood you when we were talking about the waterfall?

MR. JEFF STRONGMAN: Right. So the form of contract does not necessarily insulate you from changed conditions or substantial deviations from plan.

MR. BOB PETERS: That wasn't my question. My question was: You're now going to have to pay somebody to -- with whom you've entered into a fixed-price contract more than the fixed-price contract because the general civil contractor caused a delay.

MR. JEFF STRONGMAN: Pardon me.

MR. BOB PETERS: Do you understand my question?

MR. JEFF STRONGMAN: Okay. Sorry. I

understand your question now.

MR. BOB PETERS: All right. And in that instance, Mr. Strongman, who is responsible for paying that additional cost under the fixed-price arrangement?

MR. JEFF STRONGMAN: The owner would be responsible.

MR. BOB PETERS: That doesn't get charged back to the general civil contractor who caused the delay that caused the fixed-price contract to escalate?

MR. JEFF STRONGMAN: Not typically. That would typically be an interface that the owner retains responsibility for. So earlier, Dave talked about the knock-on effect when a -- the general civil schedule has affected and impacted other work subsequent to the concrete and earthwork structures being completed.

The service contracts that are a req -- a requirement for our -- our construction site, providing security, catering, et cetera, they're all function of time. So when the schedule takes six (6) months longer than expected, all of those contracts' duration are extended by six (6) months, and we would then incur costs equivalent to six (6) months' extension.

If we had a -- a fixed-price contract like a gates, guides, and hoist installation, if that would be impacted by the work of a previous contractor, we would then need to work out some form of resolution with the impact.

MR. BOB PETERS: Mr. Strongman, on page 63 of Board counsel's book of documents is an extract from the MGF project services report. This is a portion that was, I believe, authored by Klohn Crippen Berger -- Berger? Do you have that, sir?

MR. JEFF STRONGMAN: I have page 63 in front of me.

MR. BOB PETERS: And -- well, you know them as KCB, do you, as --

MR. JEFF STRONGMAN: Yes.

MR. BOB PETERS: And that's the company that constructs Hydro dams?

MR. JEFF STRONGMAN: Yeah. I don't have much direct experience with them, but I understand them to have worked a fair amount of Western Canada.

MR. BOB PETERS: On Hydro generating stations?

MR. JEFF STRONGMAN: Yeah.

MR. BOB PETERS: And in their review of the 2014 contract, they too called it a cost-reimbursable model, and your -- you'd like that to be corrected to say cost-reimbursable with a target price?

MR. JEFF STRONGMAN: Yes, I believe that's how we addressed our rebuttal.

MR. BOB PETERS: And in this particular review, KCB was trying to understand how the project could be as far over budget, because the variances and quantities didn't appear that high, and the initial unit prices were, in fact, low.

Do you see their statements?

MR. JEFF STRONGMAN: I see them highlighted here, yes.

MR. BOB PETERS: And you've already told this panel that the variances and quantities was not that high, correct?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: But on the next page, 64, KCB focuses on a section of the contract where it seems that actual costs that are paid to the contractor by Manitoba Hydro is not qualified by the quantities times the unit prices. Do you see that?

MR. JEFF STRONGMAN: I do.

MR. BOB PETERS: And so when KCB speaks of the actual costs, you've already acknowledged that Manitoba Hydro had to pay BBE the actual costs for the work that they actually did?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: And that actual cost was not tied to any specific quantity times a unit price?

MR. JEFF STRONGMAN: Save for the explanation I -- that I gave to how the cost of the work compares to the target price and the profit component.

(BRIEF PAUSE)

MR. BOB PETERS: KCB, then, in the middle of page 64, focuses in on the all actual indirect and direct costs incurred by the contractor or BBE in performing the work are reimbursed to the contractor, correct?

MR. JEFF STRONGMAN: That is definitely what it says.

MR. BOB PETERS: And they're quoting from the contract that Manitoba Hydro has with BBE?

MR. JEFF STRONGMAN: I presume so, but

I haven't confirmed.

MR. BOB PETERS: All right. Will you take that subject to check?

MR. JEFF STRONGMAN: Sure.

MR. BOB PETERS: All right. It -- and then want to take you to below the quote of that section. Their comment from KCB that there's no connection between actual costs and the quantities and unit prices in the bill of quantities, that's accurate, is it not?

MR. JEFF STRONGMAN: Well, I would say the same response as I did a moment ago. I -- I don't feel it's a hundred percent accurate, because in a target price contract, the linkage is through the comparison of actual cost to the target price and then the influence on the contractor's profit and GA & O as -- as an outcome. So I -- I disagree with that. It demonstrates to me that KCB did not fully understand the target price component of the contract.

MR. BOB PETERS: So long as the general civil contractor is below or underneath the target price, this statement would then be actual -- would be factual, correct?

MR. JEFF STRONGMAN: Well, not necessarily just below, below or above, within the range of influence from the provisions relating to the profit, that 80 percent, plus or minus.

MR. BOB PETERS: Once the target price has been exceeded, and the profit margin has disappeared for the general civil contractor --

MR. JEFF STRONGMAN: Yes.

MR. BOB PETERS: -- is there any incentive for BBB -- BBE to actually perform the work?

MR. JEFF STRONGMAN: No. The incentive perversably (sic) flips. In other words, there -- there appears to be more incentive to drag it out as opposed to finishing, subject to limitations on the GA & O cap.

MR. BOB PETERS: And that perverse incentive is because by dragging it out, BBE would be paid their actual costs of construction?

MR. JEFF STRONGMAN: Correct.

MR. BOB PETERS: They wouldn't be getting additional profit at that point in time?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: But they would be getting paid their actual costs of their workers?

MR. JEFF STRONGMAN: Yes. They would also get an -- a GA & O markup until that ran out, as well.

MR. BOB PETERS: Right, and you haven't put on the public record when that happens, but that would be a factor that would determine at what point they're totally -- have little incentive to perform the work?

MR. JEFF STRONGMAN: That's correct.

(BRIEF PAUSE)

MR. BOB PETERS: Mr. Midford, I don't know if you can answer this, but did Manitoba Hydro have a preference for a unit price contract for Keeyask rather than the cost reimbursable contract with the target price?

MR. LORNE MIDFORD: The original contract or the amending contract?

MR. BOB PETERS: Let's start with the original contract.

MR. LORNE MIDFORD: I'm -- I think that both Mr. Bowen and -- and Mr. Strongman provided kind of the environment when that contract was awarded, and based on the market conditions at the time, I think they've stated that there was -- and based on their experience in the award of Wuskwatim, that the unit-based approach wasn't an approach that they thought would be successful.

MR. BOB PETERS: In that answer, Mr. Midford, are you telling this panel that Manitoba Hydro did not put out a unit price contract tender for Keeyask?

MR. LORNE MIDFORD: Yes, that's my understanding.

MR. BOB PETERS: Did Manitoba Hydro put out a tender for Keeyask other than a cost reimbursable contract with a target price?

MR. LORNE MIDFORD: No.

MR. BOB PETERS: Now, in Manitoba Hydro's rebuttal, Mr. Midford, Mr. Bowen, and Mr. Strongman, I believe pages 6 and 7 of 58, there's an explanation that Manitoba Hydro did try to put out -- or did, in fact, put out a unit price contract when Wuskwatim was going out to tender, correct?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: And that yielded, Mr. Strongman, one (1) and only one (1) bidder that came back with a proposal?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: Manitoba Hydro wasn't obligated to accept any bid, and did not accept that one (1) bid, did they?

MR. JEFF STRONGMAN: That's right.

MR. BOB PETERS: Now, in the rebuttal, there's an indication that the unit price bid would have nearly doubled the engineer's estimate. Do you recall that being in your rebuttal?

MR. JEFF STRONGMAN: Yes.

MR. BOB PETERS: At what stage was the engineer's estimate back in, I suppose it was 2001 or 2002, as the Wuskwatim review was filed before the Clean Environment Commission sometime in 2003? Do you know?

MR. JEFF STRONGMAN: No, that predates my involvement by about a decade. Let me check.

MR. BOB PETERS: I indicated earlier that Mr. Williams's younger twin brother would be able to answer that, but...

(BRIEF PAUSE)

MR. BOB PETERS: Were you able to determine whether or not the engineer's estimate was at a refined stage, or was it just a preliminary calculation?

MR. JEFF STRONGMAN: I have not been able to definitively --

MR. BOB PETERS: All right.

MR. JEFF STRONGMAN: -- provide that, no.

MR. BOB PETERS: Can you tell this Board how the unit price bid for the general civil contract on Wuskwatim compared to the actual final price paid by Hydro on the general civil contract?

MR. JEFF STRONGMAN: Yes. I can say that the -- the bid provided values considerably more than the final cost outcome.

MR. BOB PETERS: So for the general civil contractor on Wuskwatim, had Manitoba Hydro proceeded on a unit price basis, they would have paid more than they actually did under a cost reimbursable with a target price contract?

MR. JEFF STRONGMAN: Yes, that's correct.

MR. BOB PETERS: And are you able to say how much more?

MR. JEFF STRONGMAN: I can't with certainty. My recollection is between 50 and 100 million more.

MR. BOB PETERS: So when we go back to -- I hate to do this, but back to page 5 of Board counsel's book of documents, and we look for

Wuskwatim, and let's just look at the very top line on this chart, because that's the Wuskwatim generating station, correct, not including the transmission?

MR. JEFF STRONGMAN: Okay. Page 5?

MR. BOB PETERS: Yes.

MR. JEFF STRONGMAN: Could you repeat the question?

MR. BOB PETERS: I'm suggesting that to -- to understand your last -- or second last answer to me, we have to look at that Wuskwatim GS line, or generating station line at the top of the chart on page 5 of Board counsel's book of documents?

MR. JEFF STRONGMAN: Okay.

MR. BOB PETERS: And by the time this project had gone to the Clean Environment Commission in 2003, Manitoba Hydro had already determined, did it, that it was not going to go out on a unit price contract?

MR. JEFF STRONGMAN: So I joined the project in 2009, approximately two (2) weeks before the first concrete by the general civil contract, O-N-E, on Wuskwatim. And the history prior to 2009 predates me, but I had done some checking in anticipation of this question, and I found that Manitoba Hydro tendered for the general civil contract in 2006, and received the one (1) bid for unit price in early 2007, determined that bid to be cost prohibitive and did not proceed. Then we went to a second procurement process through 2008 for the general civil contract. We had four (4) prequalified vendors who submitted proposals, and ultimately we selected one (1) to proceed.

MR. BOB PETERS: All right. Let's go back, then, Mr. Strongman, to 2006. That's the year in which the unit price contract was put -- a tender was put out and one (1) party responded, correct?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: And that response was considered unacceptable because it was nearly double the engineering estimate for what the general civil contractor should have been asking for?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: And so of that $1.1 billion, are you able to indicate the approximate percentage of that that would have been related to the general civil contractor, or is that something that can't be put on the public record?

MR. JEFF STRONGMAN: I would just be guessing. I -- I can't recall the exact engineer's estimate of the proponent --

MR. BOB PETERS: All right, but --

MR. JEFF STRONGMAN: -- or the percentage.

MR. BOB PETERS: -- on the generating station, the general civil contract was the largest contract for that project?

MR. JEFF STRONGMAN: It might be a third (1/3), 40 percent-ish?

MR. BOB PETERS: Okay. So if we say it's $300 million, are you with me on that?

MR. JEFF STRONGMAN: As a ballpark, yes.

MR. BOB PETERS: As a ballpark. If -- even if that bid had come back and was an extra hundred million dollars, it would have meant that you would have paid $400 million for the general civil contractor, correct?

MR. JEFF STRONGMAN: Are you talking about a hundred million worth of change conditions and executing the work?

MR. BOB PETERS: I was using the hundred million that you gave me about five (5) minutes ago.

MR. JEFF STRONGMAN: Okay. Well, we should also account for the change conditions in executing the work if we're going to take the theoretical path of proceeding with a lump sum contractor or a unit price contract right out of the gates.

MR. BOB PETERS: Okay, but let's -- let's stick with this unit price bid. Would it not be correct for this panel to look at the cost in 2006 of $1.1 billion and say, Even if it was an extra hundred million dollars, that's still coming in considerably lower than what it otherwise would have cost?

MR. JEFF STRONGMAN: Okay. Let me back up, then. So in the 2006 time frame, where the project budget was one point one (1.1) our engineer's estimate would've been a third (1/3), so we would have expected roughly a general civil contract value of in the neighbourhood of three hundred (300). And as the procurement process evolved and only one (1) bid was received, we would have considered that noncompetitive. But the value for that one (1) bid was exceedingly expensive, and by that, I mean close to double, so we would not have chosen to proceed.

Had we proceeded, we would have then made an award for a contract somewhere between 5 and 600 million, and through the execution of the work, we would have had to account for change conditions, and that would have increased the price through the three (3) to four (4) year construction phase.

(BRIEF PAUSE)

MR. BOB PETERS: And so, cut to the bottom line, it -- it came in at 1.4 billion. What would it have been under the hypothetical, had you accepted the unit price with those change conditions?

MR. JEFF STRONGMAN: So we finished the project just under 400 million with the general civil contract. I think three ninety-six (396) is the number that comes to mind, but I'd -- I'd have to confirm that.

(BRIEF PAUSE)

MR. JEFF STRONGMAN: We're trying to compare two (2) scenarios where one (1) is actual and the other is a hypothetical. So to the degree that we can, we're trying to make them comparable where change conditions may or may not affect the execution.

MR. BOB PETERS: And that's exactly correct, Mr. Strongman, and I have your -- I have your point, and --

MR. JEFF STRONGMAN: Okay.

MR. BOB PETERS: -- I think you've helped us understand that I may have misunderstood a -- a previous answer of yours that led to that clarification. So thank you.

MR. JEFF STRONGMAN: Okay.

MR. BOB PETERS: Back to Keeyask, is Manitoba Hydro able to indicate to this Board whether BBE has been paid for general, administration, and overheads in 2016?

MR. JEFF STRONGMAN: Are you referring to the period of time prior to amending agreement number 7?

MR. BOB PETERS: I am.

MR. JEFF STRONGMAN: Yes, GA & O would have been paid.

MR. BOB PETERS: It's not clawed back?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: Was it paid prior to the renegotiation of amending agreement 7?

MR. JEFF STRONGMAN: Yes.

MR. BOB PETERS: Can you indicate on the public record whether BBE has been paid any amount for profit on the 2014 original contract?

MR. JEFF STRONGMAN: Yes.

MR. BOB PETERS: You can, and yes, they have?

MR. JEFF STRONGMAN: That's correct. Both.

MR. BOB PETERS: Does the fact that BBE received profit on the original contract indicate that Manitoba Hydro took remediation steps before the contract was in a -- an -- a cost overrun position?

MR. JEFF STRONGMAN: Let me just confer with someone who has the details.

MR. BOB PETERS: Thank you.

(BRIEF PAUSE)

MR. JEFF STRONGMAN: I'm prepared to answer.

MR. BOB PETERS: Thank you. I was asking whether BBE was paid any amount for profit on the original 2014 contract?

MR. JEFF STRONGMAN: Yes. So through 2014, '15, and most of '16, the profit markup would have been included in the contractor's monthly draw. Towards the end of the year, when Manitoba Hydro recognized the need for implementing the recovery plan, the profit payment was stopped, and further than just stopping it, a clawback took place in advance of the end of the year. I believe it was November 2016. So the profit that was viewed as having ove -- been overpaid was reconciled with one (1) of the monthly draws sub -- subsequent to October 2016.

(BRIEF PAUSE)

MR. BOB PETERS: So, Mr. Strongman, you've been good at helping this panel navigate some hypothetical questions, but if we go forward from today from amending agreement number 7, and perchance if the target price in that document is exceeded, and again, there is no more profit for BBE to earn, does Manitoba Hydro have a -- a plan to renegotiate a further amending agreement with a new target price?

MR. JEFF STRONGMAN: So no. The first question is no, we don't have a -- a plan to renegotiate another amendment, but a more fulsome answer is the possibility of a repeat of what has already taken place was in our minds during the negotiations of the amending agreement number 7, and we attempted to narrow the window of possibility for that, having come to light. We are prepared to talk a little bit more about those details as the provisions that were negotiated in-camera tomorrow.

(BRIEF PAUSE)

MR. BOB PETERS: Do I take from that answer -- and thank you, Mr. Strongman -- that Manitoba Hydro is, instead of negotiating a -- a revised agreement on top of the amending agreement number 7, is prepared to expend up to the P90 number under the current arrangement?

(BRIEF PAUSE)

MR. JEFF STRONGMAN: Would you clarify the question?

MR. BOB PETERS: Well, certainly. What -- there have been the different cost estimates put on the record of these proceedings, and you've already seen the one that MGF project services has put on the record, and -- and what I'm asking is, rather than renegotiate a revision to amending agreement number 7, should this Board take Manitoba Hydro's strategy be -- to be to continue it through recognizing that the P90 number is -- is something Manitoba Hydro is prepared to pay rather than restructure the agreement yet again?

MR. JEFF STRONGMAN: One (1) moment, please.

MR. BOB PETERS: Certainly.

(BRIEF PAUSE)

MR. JEFF STRONGMAN: Manitoba Hydro is not intending on renegotiating another amending agreement.

(BRIEF PAUSE)

MR. BOB PETERS: Thank you. I'm going to turn to a new area, unless the panel wants a short recess at this time. And I'll keep going.

I want to turn ahead to page 114 on Board counsel's sixth book of document -- number 6 book of documents. This relates to a -- a matter, Mr. Strongman, you and Board member McKay were discussing, and it also talks about breakdown of the -- the total number of hires.

And on page 114, Mr. Strongman, this is the information Manitoba Hydro has with respect to the Keeyask project, correct?

MR. JEFF STRONGMAN: The numbers look correct, yes.

MR. BOB PETERS: And when Manitoba Hydro says, as they do on page 114 of Board counsel's book of documents, that there's been a total of thirteen thousand one hundred and sixty-five (13,165) hires, that doesn't mean there's been thirteen thousand one hundred and sixty-five (13,165) different people involved, does it?

MR. JEFF STRONGMAN: That's -- no, you're right. It doesn't.

MR. BOB PETERS: And does that imply, then, that one (1) person could be hired multiple times?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: And on the Keeyask project, I suppose the chart at the bottom of the page might be better than what I can see on the pie charts at the top. What you were telling the Board before was of the total hires, Manitoba Hydro has the data to determine if that individual was hired and it was a member of one (1) of the KCN partners, correct?

MR. JEFF STRONGMAN: Yes.

MR. BOB PETERS: And -- or some other Indigenous peoples rather than KCN, correct?

MR. JEFF STRONGMAN: Yes.

MR. BOB PETERS: And is that done on the basis of the self-declaring, or is there a -- a questionnaire that's provided, or how -- how is that determined?

MR. JEFF STRONGMAN: We have a contractor employment database that relies on information provided to Manitoba Hydro from the contractors executing the work, where on a monthly basis, they provide reports on who is on their payroll and various other pieces of data.

MR. BOB PETERS: All right. Can we go to the -- the pie chart at the top of page 114, please. Scroll back up to the top of the page. Please scroll back up to the top of the page.

And of these hires, the database from the human resource personnel are able to determine how many of the hires come from Northern Manitoba and how many come from other parts of Manitoba?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: And for the Northern Manitoba, again, this is where the data has been broken down specifically for KCN members and for Northern Manitobans that are non-KCN members, but other Indigenous peoples?

MR. JEFF STRONGMAN: That's correct.

MR. BOB PETERS: The same information I think is on page 112. We might as well do it right now, Mr. Bowen, dealing with Bipole III, although Mr. Mr. Fogg might want to weigh in here as well.

Sir, again, on Bipole three, the twelve thousand three hundred and fifty-two (12,352) hires on the project do not represent individual people. It could be the same person hired more than once?

MR. ALISTAIR FOGG: That's correct. It could be a rehire.

MR. BOB PETERS: Can you give an example as to why a person would be hired more than once on the -- on a -- on a project?

MR. ALISTAIR FOGG: There are a couple situations where that could occur. The best example I could think of is a person would be rehired if they were working for one (1) contractor on a phase of work, that work was completed, they applied for a position with the contractor doing the subsequent phase of work, so they'd be rehired to the project with that other contractor.

MR. BOB PETERS: And the same breakdown in terms of the hires for Bipole III is provided as it was for Keeyask, Mr. Fogg?

MR. ALISTAIR FOGG: Correct.

(BRIEF PAUSE)

MR. BOB PETERS: In someone's presentation today, there was mention that the hiring was done as a result of the Burntwood Nelson agreement, correct?

(BRIEF PAUSE)

MR. DAVID BOWEN: Yes, the -- the Bursment -- Burntwood Nelson Agreement applies to both Keeyask and the Keewatinohk converter station, and the Burntwood Nelson agreement is effectively the -- what we call the project labour agreement for -- for the work, and all craft labour that contractors use on both those project sites, there's hiring preferences within the -- the BNA that they need to follow.

MR. BOB PETERS: That BNA, or Burntwood Nelson agreement that you're referring to doesn't apply to Bipole III, does it?

MR. ALISTAIR FOGG: To clarify, that applies to the Keewatinohk converter station as part of Bipole III -- the Bipole III transmission line is under the transmission line labour agreement, and then the Riel converter station does not have a labour agreement.

MR. BOB PETERS: Did the Board understand your evidence correctly, if the -- understood that the wages in the Burntwood Nelson agreement are above the market rates in Manitoba?

MR. DAVID BOWEN: For -- for Keeyask, the wages in the Burntwood Nelson agreement generally piggyback the wages of the collective -- the CLRA in Southern Manitoba. Early on in -- for the Keeyask project, in the -- towards the end of the 2014 year, we did a analysis of wages for remote projects across the country, and what we found is that the wage rates for -- in the BNA were amongst the lowest in the country, and the that's when I mentioned that we -- we provided a -- an increase. I believe the increase was about 13 percent, and it's -- it's only earned if -- if the person continues employment for a -- and renewed quarterly, so that's -- that's what I was referring to.

MR. BOB PETERS: Can you indicate, Mr. Bowen, whether the Burntwood Nelson agreement has contributed to the cost overruns on Keeyask?

MR. DAVID BOWEN: Certainly, I'd be

willing to explore this in farther detail tomorrow, but labour is a -- a major cost for the Keeyask project, and -- and there -- there have been some challenges to date.

MR. BOB PETERS: I'm going to turn to some questions on the Bipole III, and Mr. Penner, I don't have a direct line of sight, which you don't have to complain about, but if -- if you're comfortable there, or else I could ask that --

MS. HELGA VAN IDERSTINE: If you've stopped asking questions of Mr. Strongman, he can slip into the back row and we can bring him --

MR. BOB PETERS: No, I liked his answers. He -- he gives good answers, Ms. Van Iderstine, maybe he should -- well, he can -- he can slip back for a minute. I'm going to turn to the Bipole, and then hopefully move into the MMTP, and maybe touch a couple of Mr. Cormie's as well.

(BRIEF PAUSE)

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: Mr. Fogg and Mr. Penner, I want to talk about Bipole III, and I want you to appreciate that this is a project that hasn't been before the Public Utilities Board for a Needs for and Alternative review. Is that your understanding?

MR. ALISTAIR FOGG: Yes, that's my understanding.

MR. BOB PETERS: Is it also your understanding, Mr. Fogg, that the in the beginning, Bipole III was to bring down power from Northern Manitoba related to what no doubt Mr. Cormie had a hand in, which was selling energy from Conawapa to Ontario Hydro?

MR. ALISTAIR FOGG: I'm somewhat aware, probably not as much as Mr. Cormie, of some of the history of -- of that --

MR. BOB PETERS: And he's certainly welcome to assist in any way he can.

And Mr. Penner, you were probably an engineer in training way back then, but the initial routing for the Bipole was to come to -- on the east side of Lake Winnipeg? Do you recall that?

MR. GLENN PENNER: Yes, yes, I do.

MR. BOB PETERS: And when the Ontario sale didn't continue, Conawapa didn't continue, and then Bipole III, at that point in time, didn't continue either, did it?

MR. GLENN PENNER: That is my

understanding.

MR. BOB PETERS: All right. And the while we think one (1) of your slides today was misdated, but in approximately September of 1996, there was a inclement weather, or a wind event, I think was the word used, that affected the Bipoles I and II, correct?

MR. GLENN PENNER: Yes, that's correct. The slide said 1997, and -- and my recollection was nine -- September 5th, 1996.

MR. BOB PETERS: All right. So we'll blame the person who prepared the slide. The purpose of the Bipole III is to provide redundant transmission line to mitigate the risks of the outages, correct, outages on Bipoles I and II?

MR. GLENN PENNER: Yes, that's correct.

MR. BOB PETERS: And way back when, and on page 5 of Exhibit 42-6, Board counsel's book of documents, I think the earliest indication here on this chart was Bipole III, under the capital expenditure forecast in 2003, was -- was penciled in at $360 million on an East side routing. Was that your understanding?

MR. ALISTAIR FOGG: Yes, that --

that's correct. And -- and just to clarify, it was a Bipole III East side routing, and did not include any converter stations at that point in time.

MR. BOB PETERS: And -- and that's an interesting comment, Mr. Fogg, because would Bipole III need converter stations regardless of whether there was additional generation in Northern Manitoba?

MR. ALISTAIR FOGG: I think that the key aspect of that question relates to the single terminus point at the Dorsey converter station, and without -- Bipole III would still require the Riel converter station to truly provide the redundancy that we're -- we're seeking to provide the reliability.

MR. BOB PETERS: Well, the redundancy is that -- Dorsey is the redundancy for Riel, and Riel is the done -- redundancy for Dorsey. Would you understand it that way?

MR. ALISTAIR FOGG: I guess I would explain it as Riel provides a -- a second point -- a separate point, or terminus point for a Bipole III line. So essentially, yes.

MR. BOB PETERS: So when I asked was a converter station needed regardless of the routing of the Bipole, and regardless of whether there's a new generating station in Northern Manitoba, your answer is, It has to end at a converter station somewhere?

MR. ALISTAIR FOGG: That's correct. It -- as an HVDC transmission line, it would need to end at a converter station.

MR. BOB PETERS: And I'm sure technically, it was possible for it to terminate at Dorsey, but Manitoba Hydro made a decision that rather than put, I think your words are, All their eggs in one (1) basket, you were going to move over and build the Riel converter station on the other side of the city?

MR. ALISTAIR FOGG: I believe to terminate at Dorsey still would have required additional infrastructure to accommodate Bipole III. However, you're correct in saying that from a reliability perspective, the decision would be to build Riel and the second terminus point.

MR. BOB PETERS: All right. And on that page 5 that's in front of us, we see that in that the capital expenditure forecast in 2005, the Bipole has about a 1.8 or $1.9 billion placeholder, at least, correct?

MR. ALISTAIR FOGG: That's correct.

MR. BOB PETERS: And at this point in time, Mr. Fogg, it includes a Northern and a Southern converter station, correct?

MR. ALISTAIR FOGG: That's correct.

MR. BOB PETERS: And at this point in time, it also includes a Western Manitoba routing as opposed to an Eastern Manitoba routing?

MR. ALISTAIR FOGG: I believe it -- this estimate does include a -- a Western routing, however, I -- I would believe it would be contexted as a -- as a placeholder value, as it has not been significantly analyzed in terms of the costs associated with that routing. This would have been an initial point of changing from an East side to a West side, and an initial value would have been put into the estimate before me -- more detailed costs could be assessed.

MR. BOB PETERS: What you're telling the panel is Manitoba Hydro's engineers were -- were doing planning as if it was going to be an East side routing, but they also came up with a placeholder if it was going to be a West side routing?

MR. ALISTAIR FOGG: I think what -- just to clarify what I'm saying is that Manitoba Hydro's engineers would be planning an East side Bipole III but had been asked to look at alternatives to that, and that -- at that point in time, in 2005, it would have looked at a placeholder cost of what a West -- West side Bipole III would look like.

MR. BOB PETERS: And if we go back to page 124 of Board counsel's book of documents...

(BRIEF PAUSE)

MR. BOB PETERS: Let's make that page 130. That's the end of a letter that Manitoba Hydro's Board of Directors received from the minister responsible for Manitoba Hydro, on or about September 20th of 2007, Mr. Fogg?

MR. ALISTAIR FOGG: Yes, that's correct.

MR. BOB PETERS: And the essence of that was that there was a policy decision by the Manitoba government that Bipole III should be rooted on the west side of the province, correct?

MR. ALISTAIR FOGG: My understanding would be a decision requesting alternatives to an east side Bipole III line be examined.

MR. BOB PETERS: And so those alternatives could have been the west side of the province or they could have been through the Interlake corridor?

MR. ALISTAIR FOGG: The alternatives could been a west side line or other alternatives for fal -- to provide the anticipated reliability, be it gas generation or other options such as that.

MR. BOB PETERS: So did Manitoba Hydro pursue a natural gas generator in southern Manitoba?

MR. ALISTAIR FOGG: The specific analys -- economic analysis of that would have been before my involvement on the project. But my understanding is those options were considered along with a western rooted Bipole III, and it was found that the western rooted Bipole III remained the most economical option to provide the required reliability improvements.

MR. BOB PETERS: And so while the provincial government was saying, in essence, don't use an eastern or east side of Lake Winnipeg routing, find an alternative routing, or alternative to even the Bipole III.

Manitoba Hydro determined that the best option was a Bipole III, but routed on the west side of the province?

MR. ALISTAIR FOGG: That's correct.

MR. BOB PETERS: And we see on page 131 a sketchy little map of the province that shows an east side routing or a west side route, as well as in Interlake corridor route, correct?

MR. ALISTAIR FOGG: That's what it shows, that's correct.

MR. BOB PETERS: And at this point in time -- this, Mr. Fogg, I should've identified was -- I believe it was -- it was in the Boston Consulting Group report, although the source of it indicates, in the bottom left-hand corner, at Teshmont, 2006?

MR. ALISTAIR FOGG: That appears to be what it states, yeah.

MR. BOB PETERS: And you're familiar with Teshmont being an engineering firm in the city?

MR. ALISTAIR FOGG: Yes, I am.

MR. BOB PETERS: As a result of the west side routing, it appears that the physical distance is longer. And I know you put on the record this morning the exact distance, but it's clear on this map that Bipole III on the east was 855 kilometres, and the Bipole III on the west side would be 1,341 kilometres, correct?

MR. ALISTAIR FOGG: Yes, I believe the graph says 885 kilometres for the -- the eastside, and then 1,341 kilometres for the west.

MR. BOB PETERS: Thank you, if I

misspoke, for correcting me. And I believe, but I don't have the number handy, it was within a few kilometres, the actual length, correct?

MR. ALISTAIR FOGG: Sorry, for the -- the current west side line?

MR. BOB PETERS: Yeah --

MR. ALISTAIR FOGG: It would be a 1,388 kilometres actual -- actual built length, correct.

MR. BOB PETERS: And it stands to reason that longer distance will mean more towers, more conductors, or longer conductors and wires, correct?

MR. ALISTAIR FOGG: Correct.

MR. BOB PETERS: And as a result of those decisions to go down the west side, what does Manitoba Hydro estimate to be the increased costs for Bipole III as a result of the west side routing and not a routing on the east side of Lake Manitoba?

MR. ALISTAIR FOGG: If you could just give me one (1) second.

MR. BOB PETERS: Certainly.

(BRIEF PAUSE)

MR. ALISTAIR FOGG: Mr. Peters, I don't have that number specifically at hand. That was -- would be something I'd have to look into. But gen -- generally speaking, you could look at those distances and -- and you would expect a longer distance would be more expensive.

MR. BOB PETERS: While you don't have those numbers at hand, Mr. Fogg, do you -- are you able to undertake to provide them to the Board?

MS. HELGA VAN IDERSTINE: I'll jump -- I'll jump in. We'll take it under advisement at the moment. I'm not certain that those numbers are available or if they are relevant to the hearing at this moment, so.

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: Well, Mr. Fogg, on page 132 of Board counsels' book of documents, again, it's a slide from the Boston Consulting Group.

Were you familiar with that?

MR. ALISTAIR FOGG: Yes, I am.

(BRIEF PAUSE)

MR. BOB PETERS: And on this page,

halfway down on the left side, the cost estimate used in 2011 EIS, do you know what that was?

MR. ALISTAIR FOGG: Yes, the Environmental Impact Statement.

MR. BOB PETERS: And that was prepared by Manitoba Hydro?

MR. ALISTAIR FOGG: Correct.

MR. BOB PETERS: And is it correct that Manitoba Hydro quantified the route on the west side to be approximately $900 million more expensive than the east side of Lake Winnipeg?

MR. ALISTAIR FOGG: That's what the slide say.

MR. BOB PETERS: And I'm asking you if that was -- if that's factual.

MR. ALISTAIR FOGG: I'm not specifically familiar at that number. I would -- that would have to be confirmed.

MR. BOB PETERS: You'll take that subject to check?

MR. ALISTAIR FOGG: Yes.

MR. BOB PETERS: And so when you're looking to tell this Board whether Manitoba Hydro has an estimate for the additional costs for Bipole III to be on the west side of Manitoba, as opposed to the east side, you can indicate whether this $900 million number that Manitoba Hydro provided in their environmental impact statement is also accurate.

Would be acceptable?

MS. HELGA VAN IDERSTINE: I'm just going to clarify, what do you mean by "accurate" in this context? I mean, if that's the number that -- I wasn't at the environmental impact -- the -- or didn't -- involved in that environmental impact statement. But I'm presuming if the number was presented at that time, it was accurate at that time.

MR. BOB PETERS: That's what we want to confirm, if we could, Ms. Van Iderstine --

MS. HELGA VAN IDERSTINE: You're not looking --

MR. BOB PETERS: -- and if you --

MS. HELGA VAN IDERSTINE: -- for anything else?

MR. BOB PETERS: Pardon me?

MS. HELGA VAN IDERSTINE: But you're not looking for anything else?

MR. BOB PETERS: Not related to this number, no. But I did ask Mr. Fogg earlier if Manitoba Hydro had a -- a calculation at this point in time of what that number would be, and you we're going to take that under advisement.

MS. HELGA VAN IDERSTINE: Yes. I'm -- I'm pretty concerned about relevance, so.

MR. BOB PETERS: All right. Thank you.

(BRIEF PAUSE)

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: On page...

(BRIEF PAUSE)

MR. BOB PETERS: I've been asked to -- to put on the record, Mr. Fogg, Ms. Van Iderstine, what the request was that the Manitoba Hydro has agreed to take under advisement. And I was asking Manitoba Hydro to provide the Board with its current estimate of the additional costs of Bipole III being on the western side of the province compared to the eastern side of Lake Winnipeg.

And included in that was a request to review the number that Manitoba Hydro put forward at the Clean Environment Commission proceeding, and confirm that it was accurate when given.

MS. HELGA VAN IDERSTINE: That's a whole -- a whole bunch of questions. I'm going to take all of them under advisement. And I suspect that we'll be able to answer the ones that I have identified earlier, but rather than try to parse them now, I think that's the easiest way to address it.

MR. BOB PETERS: All right. Let's proceed then.

--- UNDERTAKING NO. 58: Manitoba Hydro to provide the Board with its current estimate of the additional costs of Bipole III being on the western side of the province compared to the eastern side of Lake Winnipeg; and to review the number that it put forward at the Clean Environment Commission proceeding, and confirm that it was accurate when given. (TAKEN UNDER ADVISEMENT)

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: Mr. Fogg, on page 137 of Board counsels' book of documents, Manitoba Hydro responded to an Information Request at a prior General Rate Application, and carried forward the cost of Bipole III from $3.2 billion to $4.65 billion, correct?

MR. ALISTAIR FOGG: Correct.

MR. BOB PETERS: And in this -- in this Information Request, Manitoba Hydro was able to break down the transmission lines and keep that separate from the converter station costs. Also correct?

MR. ALISTAIR FOGG: That's what it shows us, correct.

MR. BOB PETERS: And then, in terms of the converter station costs, let's keep that 2.6 or $2.68 billion number in mind and turn to page 140 of Board counsels' book of documents. Actually make that page 141.

The converter station costs that are now on Manitoba Hydro's capital expenditure forecast have gone up from the $2.68 billion, they've gone up by $105 million, Mr. Fogg?

MR. ALISTAIR FOGG: That's correct.

MR. BOB PETERS: And I'll come back to that point. But let's do the same here on the transmission line, on page 140.

The transmission line was initially budgeted at $1.65 billion, and that has gone up another $302 million, correct?

MR. ALISTAIR FOGG: That's correct.

MR. BOB PETERS: And so that puts the overall project for Bipole III increasing from $4.65 billion to $5 billion?

MR. ALISTAIR FOGG: That's correct.

MR. BOB PETERS: And the causes of the converter station increase, I think can be seen on page 144, Board counsels' book of documents. Well, it can't be seen that well.

Below the redacted waterfall chart from the MGF report, Manitoba Hydro indicates that contributing to the converter station costs were costs that Manitoba Hydro had to pay to upgrade a couple of provincial roads.

Is that correct?

MR. ALISTAIR FOGG: There were costs that were -- were previously assumed to be shared with the Conawapa project that is not proceeding, that were now to be funded by the Bipole III project for those provincial roads, yes.

MR. BOB PETERS: We can scroll down to the bottom half of the page.

Mr. Fogg, I understood your answer to say Manitoba Hydro had to upgrade Provincial Roads 280 and 290, correct?

MR. ALISTAIR FOGG: We contributed funds to the upgrading of those provincial roads, yes.

MR. BOB PETERS: And you contributed funds because you wanted to use that road should Conawapa come in-service, but you also needed it for the Bipole III project?

MR. ALISTAIR FOGG: The Provincial Road 280 -- upgrades, Provincial Road 280, serves the Bipole III project and also the Keeyask project. So there would be upgrades required to that road to address construction traffic for those projects.

Provincial Road 290 serves the Bipole III project and would've served the Conawapa project, as well. And that road, similarly, as a result of Keewatinohk construction, would require upgrades due to the construction traffic.

MR. BOB PETERS: So whatever was included on the Conawapa side of the ledger, you've transferred that all to the Bipole III side?

MR. ALISTAIR FOGG: Correct.

MR. BOB PETERS: And on the Provincial Road 280, are all of the costs on Bipole III, or did some of that stay with Keeyask?

MR. ALISTAIR FOGG: I believe Keeyask has some of those costs as well.

MR. BOB PETERS: And when you talk about the Conawapa access road upgrades, those again were costs that used to be on Conawapa's ledger, but are now transferred over the Bipole III?

MR. ALISTAIR FOGG: Those would have been shared costs with the Conawapa project. That is the private road that Manitoba Hydro owns that accesses the Keewatinohk site, that would've also accessed proposed Conawapa generating station site.

MR. BOB PETERS: And the Chairman talked with you about this as well earlier after lunch today. One (1) of the reasons for increasing the converter station costs was to increase to a confidence level of -- of P75, correct?

MR. ALISTAIR FOGG: That's correct.

(BRIEF PAUSE)

MR. BOB PETERS: In turning to the

causes for the $300 million increase on the transmission line, I'd like to go to page 147 of the book of documents, please, and below the chart.

What we're telling the public here, Mr. Fogg, is that the $300 million of additional costs were in some way related to increases for the transmission line itself, correct?

MR. ALISTAIR FOGG: I believe, yes, there were increases to the transmission line costs. I believe, on page 148, the reasons for those increases are further documented.

MR. BOB PETERS: And that includes the line being longer, more land needing to be acquired, more legal fees being incurred?

MR. ALISTAIR FOGG: Mr. Peters, I -- I'm not sure I would say more land needing to be acquired, necessarily, but the actual costs to acquire that land was incorporated into the budget.

MR. BOB PETERS: And when you say Bipole III transmission line vehicles, what additional cost is that for?

MR. ALISTAIR FOGG: Those would be construction site vehicles.

MR. BOB PETERS: And again, on the contingency, we're talking about additional costs on the line going from a P50 to a PS75?

MR. ALISTAIR FOGG: Specific to the line, when we've looked at the contingency for the Bipole III project, we have looked at converter stations and transmission line separately, and then have combined them together as a whole.

Bipole III project -- as it notes here, there is an increase to the transmission line contingency from P50 to what would amount to P80, but essentially the Bipole III project perspective that's a -- it's a P75 estimate currently.

MR. BOB PETERS: Turning to page 150 of Board counsels' book of documents.

The risks that materialized for Bipole III that contributed to the $400 million overall increase in costs, Mr. Fogg, only one (1) of the risks identified had a dollar impact in excess of $20 million, and more than a six (6) month delay in the project.

Is that correct?

MR. ALISTAIR FOGG: That's what the table shows, yes.

MR. BOB PETERS: And that unforeseen risk was geotechnical?

MR. ALISTAIR FOGG: That's correct.

It was a geotechnical risk at the Keewatinohk converter station.

MR. BOB PETERS: That schedule -- that schedule risk was mitigated, and there's no delay as a result of this, is that also true?

MR. ALISTAIR FOGG: That's correct there. The -- the scheduled risks associated with this, these unforeseen conditions, was mitigated, and there's no impact to the Bipole III schedule.

MR. BOB PETERS: But there was an impact to the Bipole III budget?

MR. ALISTAIR FOGG: There is a cost impact to this risk event, and -- and the final value of that impact is still being assessed and negotiated.

MR. BOB PETERS: On Bipole III, Mr. Fogg, it appears on page 155 of Board counsels' book of documents, that Manitoba Hydro used at least three (3) forms of contracts, that being a lump sum, a unit price, and cost reimbursable, correct?

MR. ALISTAIR FOGG: That's correct. The project uses all three (3) of those forms of contracts.

MR. BOB PETERS: And that's for both the converter station as well as the transmission line?

MR. ALISTAIR FOGG: That's correct.

(BRIEF PAUSE)

MR. BOB PETERS: Before we leave that tab, on page 156, the conclusions and recommendations from MGF were that Hydro's choice of compensation mechanisms was appropriate for the contracts required. And that was for the converter stations, and was a sensible allocation of risk as between Hydro and its contractors.

Do you see that?

MR. ALISTAIR FOGG: Yes, I see that.

MR. BOB PETERS: Manitoba Hydro doesn't disagree with that, does it?

MR. ALISTAIR FOGG: We don't disagree with that, no.

MR. BOB PETERS: Okay. On page 163 of Board counsels' book of documents is a chart, in terms of the completion, out of one of Manitoba Hydro's quarterly reports.

(BRIEF PAUSE)

MR. BOB PETERS: On page 162. I

apologize.

We see at the right side of this schedule, Mr. Fogg, the in-service date that you told us about is -- we're seeing July of 2018?

MR. ALISTAIR FOGG: It would be the end of July, 2018, yes.

MR. BOB PETERS: And MR. DOUGLAS SMITH: you told the Board earlier this morning, that schedule is still valid?

MR. ALISTAIR FOGG: That's correct. That's -- we are still on target to achieve that in-service date of July, 2018.

MR. BOB PETERS: And the transmission line itself is to be completed in March of 2018, if I read this correctly?

MR. ALISTAIR FOGG: That's correct.

MR. BOB PETERS: And one (1) of the risks related to the transmission line was weather. But, perhaps, in the perverse or inverted way, Manitoba Hydro needs cold weather in which to construct the Bipole III line.

Is that correct?

MR. GLENN PENNER: We need cold weather, but not too cold.

MR. BOB PETERS: Why do you need cold

weather?

MR. GLENN PENNER: Most of the northern access is on a winter trails, and warm weather tends to make it very difficult to get between sites.

MR. BOB PETERS: And so the weather risk is Manitoba Hydro needs cold weather to complete the northern portions with frozen ground or frozen earth?

MR. GLENN PENNER: That's correct.

MR. BOB PETERS: And we're in the middle of January. Is everything running according to schedule at this point in time, with respect to the transmission line construction?

MR. GLENN PENNER: We are targeting March 1 on many of our segments, which gives us a few weeks buffer. We feel that usually -- we can usually expect winter weather until the end of March, so we are currently on schedule.

MR. BOB PETERS: On page 112 of Board counsels' book of documents is an extract, I believe -- no...

(BRIEF PAUSE)

MR. BOB PETERS: On page 16 -- on page 165, Board counsels' book of documents, MGF raises a risk, Mr. Penner, and that relates to the performance of one (1) of your contractors on the Bipole III line, correct?

MR. GLENN PENNER: That is correct.

MR. BOB PETERS: Have those performance concerns manifest themselves?

MR. GLENN PENNER: Yes, we -- we descoped a portion of the Rokstad's contract, and we have awarded that to a -- a third contractor. So there is now another contractor working on a portion of Bipole.

MR. BOB PETERS: And so on -- on page 168 of Board counsels' book of documents, in the top part of the page, MGF raises a concern that if the construction was not completed, it will cost on the schedule an additional year, correct?

MR. GLENN PENNER: That's what they have said, yes.

MR. BOB PETERS: And because Manitoba Hydro has descoped one (1) of your contractors and hired a -- an additional contractor, has all of that risk been mitigated?

MR. GLENN PENNER: We are continuing

to closely monitor all of the work on the project, and I think we -- we continue to -- to make decisions to ensure that we will be complete by the end of this winter season.

MR. BOB PETERS: That meeting March 2018?

MR. GLENN PENNER: Correct.

MR. BOB PETERS: Is there an additional cost component as a result of descoping one (1) contractor and engaging another?

(BRIEF PAUSE)

MR. GLENN PENNER: There are additional costs to -- to add another contractor. However, we had sufficient contingency within the current control budget to cover that.

MR. BOB PETERS: So the real risk is for schedule, as opposed to cost?

MR. GLENN PENNER: That's correct.

(BRIEF PAUSE)

MR. BOB PETERS: At page 49 of Exhibit 42-6, Board counsels' book of documents, we see from the MGF report for the Bipole III transmission line, that the critical paths for both of two (2) contractors are slipping, which jeopardizes completion in August of 2018, correct?

Mr. Penner, do you see that?

MR. GLENN PENNER: I do see that, yes.

MR. BOB PETERS: This raises not only one (1) contractor but two (2) of the contractors.

Have -- have -- has whatever work been slipping been corrected?

MR. GLENN PENNER: Our other contractor is on track to -- to completion, and we don't have significant concerns about their performance.

MR. BOB PETERS: Thank you. I want to turn to the Manitoba-Minnesota Transmission Line. And perhaps to orient the panel, if we flip back to page 5 of Board counsels' book of documents, we can see at the bottom of the chart, near the bottom of the chart, the price for the Manitoba-Minnesota Transmission Project was $350 million in Capital Expenditure 13, which would have been used at the Needs For And Alternatives To review.

Is that correct?

MR. GLENN PENNER: That is correct.

MR. BOB PETERS: And what level of project definition was that $350 million based on?

MR. GLENN PENNER: Can you clarify?

MR. BOB PETERS: Well, we've seen in some of the other evidence, that Manitoba Hydro's capital projects are quantified under various levels or degrees of estimates and planning.

Are you aware of that?

MR. GLENN PENNER: And so, in -- in general terms, I would say it was a -- it was a -- a higher level estimate without a probability associated with the contingency.

MR. BOB PETERS: That means that -- well, let's turn to page 171 of Board counsels' book of documents.

Here's some Manitoba Hydro rebuttal, this time to the METSCO company, and it talks about at the time certain projects were conceived the process required the budget to be estimated and approved prior to any engineering or planning being done to define the project scope. Hence, the initial budget estimate was created without a clear definition of scope.

Do you see that in the rebuttal from Manitoba Hydro?

MR. GLENN PENNER: Yes, I see that.

MR. BOB PETERS: Does that apply to the Manitoba-Minnesota Transmission Line Project, back in 2013?

MR. GLENN PENNER: One (1) moment.

(BRIEF PAUSE)

MR. GLENN PENNER: So for the $350 million estimate, we -- we didn't have a final preferred route, we didn't have any of the environmental conditions, and we didn't have any design work completed on it. So you -- you could say it was -- was a more preliminary estimate.

MR. BOB PETERS: And just so this panel understands that, Mr. Penner, those preliminary estimates are still submitted for approval to the executive of Manitoba Hydro through the capital proce -- project justification process?

MR. GLENN PENNER: Yes, that's correct.

MR. BOB PETERS: And Manitoba Hydro's executive is aware as to what level those costs have been engineered or -- or planned?

MR. GLENN PENNER: Yes, they would be.

MR. BOB PETERS: In the file -- in the

September of 2017, if we go to page 172, we see that the cost of the Manitoba-Minnesota Transmission Line Project increases up to $453 million, correct?

MR. BOB PETERS: That's correct.

MR. BOB PETERS: And that's your most current cost estimate?

MR. GLENN PENNER: That is our most current cost estimate.

MR. BOB PETERS: And that 30 percent increase is partly related to a more and a better refined scope and engineering for the project?

MR. GLENN PENNER: Correct. We have -- we have a final pref -- or a final preferred route. We -- we know more about the construction costs based on our most current Bipole III construction tenders.

MR. BOB PETERS: And we see on page 175, the capital project justification addendum, that increases the cost up to -- up a hundred million dollars to 453 million, and the various components of it, correct?

MR. GLENN PENNER: Yes, that's correct.

MR. BOB PETERS: Now, it appears that licensing and environmental assessment went up $17 million, on page 175, correct?

MR. GLENN PENNER: Correct.

MR. BOB PETERS: That was before the National Energy Board decision requiring Manitoba Hydro to pursue a certificate rather than a permit for this project?

MR. GLENN PENNER: Yes, that's correct.

MR. BOB PETERS: Can you tell this Board how much more it will cost for certificate than a permit?

MR. GLENN PENNER: One (1) moment.

(BRIEF PAUSE)

MR. GLENN PENNER: We don't have those additional costs. However, we don't expect that they -- they will be as significant as the -- the CEC hearing process.

MR. BOB PETERS: Sorry, I didn't understand that. The -- the additional cost to get a certificate will be less than it would be if you had to do a Clean Environment Commission proc -- proceeding in Manitoba?

MR. GLENN PENNER: Yes, because what we did -- we started in 2012, and we did all of our --

our CEC process begins long before the hearings. And we do our -- our public consultation, we do our environmental assessments, and we submit that information. And then we go through the hearing process.

All of that work is -- at least my understanding is that that work is submitted as evidence into the NEB process. So we're not doing, at this point, any additional environmental studies, and all those kinds of things.

So we're -- we're going through now an IR process with the NEB, leading up to a hearing sometime this spring.

MR. BOB PETERS: On page 179, flipping over to 180, is the Clean Environment Commission Report on the Manitoba-Minnesota Transmission Project correct?

MR. GLENN PENNER: Yes, that's correct.

MR. BOB PETERS: And there are recommendations that have been reproduced, starting on page 180, carrying through to 182.

You're familiar with those?

MR. GLENN PENNER: Yes.

MR. BOB PETERS: Have all of those

recommendations been accepted by the Government of Manitoba.

MR. GLENN PENNER: We have not heard yet.

MR. BOB PETERS: If any of those recommendations are accepted and required to be done by Manitoba Hydro, does that mean Manitoba Hydro has to spend more money on the Manitoba-Minnesota Transmission Project.

MR. GLENN PENNER: No, we've reviewed these recommendations and -- and feel that, for the most part, they're within the -- the within the budget and typical are expected.

MR. BOB PETERS: Did the Clean Environment Commission recommend any changes in the route?

(BRIEF PAUSE)

MR. GLENN PENNER: I'm not aware that the CEC made any recommended changes to the route. However, it's pointed out to me that nine point four (9.4) is an open-ended recommendation that -- that could cause some problems around planting trees to -- to screen the view of -- of the transmission line.

MR. BOB PETERS: Manitoba Hydro hasn't taken that into account in the project cost?

MR. GLENN PENNER: No, it's not taken an account in -- in the project cost.

MR. BOB PETERS: Is it covered by the P75 figure?

MR. GLENN PENNER: It's an open-ended recommendation that we don't fully understand.

MR. BOB PETERS: All right. Let's turn to page 173 and look at a map. I think we saw this in your slide deck as well, Mr. Penner. The bottom of the page there's a map for the Manitoba-Minnesota Transmission Project.

That's the projected route, is that correct?

MR. GLENN PENNER: Yes.

MR. BOB PETERS: And I believe in conversations with the Chairman after lunch today, you indicated that the transmission starts over at Dorsey, on the west side of Winnipeg, goes around the south end of the city, close to the Riel station, and then heads straight west, correct?

MR. GLENN PENNER: Correct.

MR. BOB PETERS: And when we look at that line going straight west of Riel, it's to approximately to -- as far as a Anola, correct?

MR. GLENN PENNER: Yeah, just past -- just east of Anola.

MR. BOB PETERS: How many kilometres or miles would that be?

(BRIEF PAUSE)

MR. GLENN PENNER: I would estimate it's about 30 kilometres.

MR. BOB PETERS: I'm sorry, I was not listening.

MR. GLENN PENNER: I am estimating approximately 30 kilometres without doing any measurements.

MR. BOB PETERS: All right. Thank you. I was listening now.

I'm looking at this map on the screen, and the Board will note that there is a dotted black line that also comes out of this solid blue line of the MMTP route, correct?

MR. GLENN PENNER: That's correct.

MR. BOB PETERS: That dotted line represents the -- is it the Dorsey-Forbes line or whatever it's now called?

MR. GLENN PENNER: Yes, it -- it used to be known as Dorsey to Forbes RD602F, and now it -- it terminates at Riel, and now it's referred to as M602F.

MR. BOB PETERS: In any event, regardless of what it's called, it appears to be how -- how far apart is it from the MMTP project?

MR. GLENN PENNER: It lies in the same corridor for that distance.

MR. BOB PETERS: So for the 30 kilometres or so that you estimated, those two (2) transmission lines are in the same corridor or just metres apart?

MR. GLENN PENNER: Yes, that's correct.

MR. BOB PETERS: Why would you prefer that routing to something separate, when the whole theory of the Bipole routing is to provide separation as between major transmission lines?

(BRIEF PAUSE)

MR. BOB PETERS: Mr. Chair, while the witnesses are conferring on this topic, I would beg indulgence for another thirty (30) minutes, if the

Board was so inclined. But if the Board had other commitments, I will try to find the time tomorrow morning after my colleagues opposite have had the microphone.

I apologize for not raising it sooner. I would like to cover a couple more topics, but if not today, then tomorrow. And if the panel would like to stand down for a short break, I'm amenable as well, but that's fine.

THE CHAIRPERSON: Yeah, we'll -- we'll break for ten (10) minutes.

MR. BOB PETERS: All right. Thank you.

--- Upon recessing at 5:28 p.m.

--- Upon resuming at 5:40 p.m.

THE CHAIRPERSON: Mr. Peters...?

MR. BOB PETERS: Thank you, Mr. Chairman.

CONTINUED BY MR. BOB PETERS:

MR. BOB PETERS: Mr. Penner, you were seeking some counsel with your colleagues at the time of the recess, did you have an opportunity to discuss with them?

MR. GLENN PENNER: Yes.

MR. BOB PETERS: And your answer then to the information you were seeking?

MR. GLENN PENNER: So yes, while it does parallel existing infrastructure, it -- it -- it was looked at very carefully by our system planning engineers and it meets in their reliability standards and some of the factors that weighed into that were that it's an east-west portion of the line. Most of the weather events occur with a westerly winds, so, there's a -- there's a change in -- in that and so that's significant.

And the other component to it is -- that it's very easy to access and very quick to have to go back in and -- and put transmission towers up, if they were to come down as a result of a major storm.

MR. BOB PETERS: So compounding that answer, Mr. Penner, is Manitoba Hydro has in that one (1) corridor -- you gave it a fancy number M602F.

Have I got that right?

MR. GLENN PENNER: Yes.

MR. BOB PETERS: Do you guys really give it numbers like that, that's incredible. That's how it's known?

MR. GLENN PENNER: That's correct. The 'M' and the 'F' refer to the stations that it starts and stops and the -- the digits in between kind of -- can tell you what line designation and the voltage class.

MR. BOB PETERS: Obviously. But on this same map that we're looking at where we see the blue line coming from Riel going as far as -- just past Anola, is the Panel correct in understanding that Bipole III is also going to join that corridor?

MR. GLENN PENNER: Bipole III is also in that corridor for a short duration as well.

MR. BOB PETERS: So a short duration, shorter than 30 kilometres?

MR. GLENN PENNER: Yes, that's correct.

MR. BOB PETERS: And so now you've got two 500 kV and the Bipole III all on the same corridor?

MR. GLENN PENNER: That's correct.

MR. BOB PETERS: Thank you. Couple of quick -- let me finish...

You told the Chairman after lunch that the $453 million in-service cost was at a preliminary stage because that's before any shovels are in the ground; correct?

MR. GLENN PENNER: No, I think I referred to the three fifty million (350) as a preliminary budget. We refer to the four hundred and fifty-three (453) now as a P75 estimate.

MR. BOB PETERS: All right but that P75 estimate or that $100 million increase from three fifty-four (354) to four fifty three (453) is before any contracts are signed for any of the work to begin on the construction of the MMTP line?

MR. GLENN PENNER: Yes. So there are no construction contracts. They haven't been signed. We haven't even put the construction contracts out to tender yet.

MR. BOB PETERS: If we compare the stage that this project is at to where Bipole III is at, isn't it correct that once the Bipole III bids were received between the bids to the actual price there was a 17 percent increase in the transmission line?

You take that subject to check?

MR. GLENN PENNER: We tendered the project in phases and the last piece -- the last half of the project was -- was actually awarded after the -

- the budget was raised to the 5.04.

MR. BOB PETERS: Okay, I've got your point on that. We heard that Hydro is committed to the June 2020 in-service date for this MMTP; correct?

MR. GLENN PENNER: Yes, that's correct.

MR. BOB PETERS: And we talked about the National Energy Board requiring Manitoba Hydro to seek a certificate; correct?

MR. GLENN PENNER: Yes, that's correct.

MR. BOB PETERS: And typically how long will it take to get a certificate compared to how long it would take to get a permit?

MR. GLENN PENNER: Maybe I could answer the question this way. The -- the process that the NEB has identified is that there -- they have fifteen (15) months, and they've deemed that -- their -- their timeline to be March 2019.

MR. BOB PETERS: That is, the project will be -- will have gone through the certificate process and will have been concluded by March 2019?

MR. GLENN PENNER: Yes, they have fifteen (15) months from the time they deemed that the documents are complete to the time that -- that they need to prepare a recommendation.

MR. BOB PETERS: Can Manitoba Hydro construct the Manitoba Minnesota transmission line in thirteen (13) months?

MR. GLENN PENNER: I think it would be difficult. We are, however -- however, hopeful that once the -- the hearing is complete sometime later this spring or early summer that we would get a recommendation sooner than the March 2019 date and -- and so that we -- we are hoping that that's a possibility.

MR. BOB PETERS: Well, I had heard earlier that hope is not a plan but you're telling me that that's what you're relying on now for the Manitoba Minnesota transmission line is hopefully getting an early ruling?

MR. GLENN PENNER: I wouldn't say we're relying on it. We are not prepared to change our June 2020 in-service date until we determine that we cannot achieve a 2020 -- a June 2020 in-service date. And so we have to look at all of the factors as we move forward. Right now, it's -- it's a hypothetical to determine other than that June 2020 in-service date.

MR. BOB PETERS: All right. I've got

your point. On page 183 of Board counsels' book of documents, in the MGF report Manitoba Hydro's costs were measured against a benchmark provided by MGF and Stanley Consulting.

You're aware of that?

MR. GLENN PENNER: Yes.

MR. BOB PETERS: You're aware of the industry benchmarked used by Stanley Consulting and MGF?

MR. GLENN PENNER: I have had a look at their -- their industry benchmark, yes.

MR. BOB PETERS: Do you agree with the industry benchmark that was used?

MR. GLENN PENNER: I think it can be difficult to determine exact line -- per kilometre line costs. I -- I think it's -- it's very hard to compare the different lines across North America.

MR. BOB PETERS: Can you explain to this Board, why Manitoba Hydro's cost is 25 percent lower than the benchmark?

MR. GLENN PENNER: I think historically Manitoba Hydro has been able to build transmission lines for less than -- than other Utilities. Primarily it -- transmission lines can vary in cost depending on the density of population if it's travelling in -- in urban areas. If there's a lot of line angles and it. So there's -- there's a variety of -- of different factors that -- that weigh into it. The type of structures that are used.

In this case where we use guide structures, I think our transmission line costs are -- are less expensive than -- than typical industry standards.

MR. BOB PETERS: In my haste I glossed over page 115 of Board counsels' book of documents and we should go back and if it was Mr. Strongman who has to give an answer, I'll -- I'll let the panel decide.

On page 115, there's an indication and I'll just read into the record that:

"Manitoba Hydro advised MGF that they have had great success with local Aboriginal labour. However, they have exhausted all availability."

Have I read that correctly? Mr. Bowen or Mr. Strongman from the back?

MR. JEFF STRONGMAN: Hi. I see the quote that is being referred to. In fact, this quote was subject of some discussion between Manitoba Hydro and MGF because Manitoba Hydro believe that although

MGF advised that they had been -- they had received this as a direct quote from one (1) of our project staff, Manitoba Hydro's view of this topic is that while we have had some success with some of the smaller communities within our partnership, Manitoba Hydro's position is that we continue to look for more opportunity and that we have not necessarily exhausted all availability.

So Manitoba Hydro believes that going forward we will continue to review with our partners employment opportunities and that we are not at the point where we can't do better. We will continue to do better.

MR. BOB PETERS: What efforts has Manitoba Hydro taken to source all available local Aboriginal labour?

MR. JEFF STRONGMAN: Within the Joint Keeyask Development Agreement, there are three (3) subcommittees that are active on a monthly basis. One of which is dedicated specifically to employment and Manitoba Hydro and the four (4) partners meet regularly to identify people within the communities that are currently looking for work and Manitoba Hydro and its contractors intend to act on those as opportunities.

MR. BOB PETERS: So Manitoba Hydro is of the understanding that there is still available employment in northern Manitoba with local Aboriginal labour being available?

MR. JEFF STRONGMAN: Yes, that's correct. I mentioned earlier that with some of the labour hours that we had quoted, roughly, 40 percent of our labour hours worked on this job by the end of 2017 were performed by Aboriginal employees and that statistic is unprecedented across Canada. We still believe that we can do better.

MR. BOB PETERS: And what steps are you taking to do better?

MR. JEFF STRONGMAN: Could I confer with my colleagues? I'm at the different table here.

MR. BOB PETERS: Yes, absolutely, Mr. Strongman, I appreciate. Thank you.

MR. DAVID BOWEN: I'll just add to Mr. Strongman's answer. He spoke about the AGE committee, the Advisory Group on Employment. So that's one (1) committee that has all our contractors. It has the folks that work at the job referral service. So really, the -- if you want to apply for a job for Keeyask, you have to submit your name within the -- what's called the JRS, the job referral service.

It has that within each of our -- our four (4) partner committees, there's a JRS worker who's -- is really for -- for lack of better words, look -- hoping to source the talent within that community to link with the province and the JRS with our contractors hiring and, of course, our Manitoba Hydro staff help that process. So that -- that is at -- continuing -- continually at work.

Some of the other efforts that are -- are other ways that -- we've typically in the last two (2) years have gone to each of the four (4) partner communities to do a job fair with the contractors working at site to make sure people are aware of what the job opportunities are and -- and help -- help get people to the site.

Other examples, we've had, of course, high school students come to site. We've actually had -- I believe it's for a -- don't quote me on this one, but it's a -- there's a work experience option where we had about just over ten (10) -- ten (10) people from the communities come to Keeyask for -- for a number days to see what it's like to -- to be at camp, see what it's like to potentially work at the camp and so -- so those are just some of the -- the efforts that are being weighed -- made to -- to increase the employment for our partner communities and, of course, Indigenous people in the north.

MR. BOB PETERS: Mr. Bowen, maybe your last comment covered this, but I understood there was a job referral service worker from each of the four (4) KCN partners; is that what I've understood?

MR. DAVID BOWEN: That's correct.

MR. BOB PETERS: And so the question becomes: For the communities that aren't part of the KCN partnership, how is Manitoba Hydro recruiting additional Aboriginal workers?

MR. DAVID BOWEN: Our -- our focus is certainly on our partner communities, and that's -- that's our -- that's our primary focus. Certainly, there's -- there's word of word-of-mouth. We have linked -- the other piece that I didn't mention was that we have linked with the -- what's called the -- the trades coordinator for the -- Partnership Manitoba. We -- there's an Aboriginal coordinator within the Thompson area to -- to get the word out and to help -- help potential people looking for work to -- to get employment Keeyask.

MR. BOB PETERS: All right. Thank you. If in your discussions with Mr. Strongman you have additional information to add, I'd ask you to put that on the record. I won't ask for that as an undertaking but you can discuss with him when you're in closer proximity than you are now.

Would you do that, sir?

MR. DAVID BOWEN: Yes.

(BRIEF PAUSE)

MR. BOB PETERS: Thank you for that. Mr. Cormie, finally, six o'clock. Thank you for patience.

In the information provided at page 195 of Board counsels' book of documents, are the Great Northern transmission line project information as provided; correct?

MR. DAVID CORMIE: Yes. Yes, I see that.

MR. BOB PETERS: And in this -- in this document, the capital cost estimate is at $677 million as of December 31st, 2015 and if we could go to the top of the page we'll see, Mr. Cormie, what I was referring to in terms of the quarterly update?

MR. DAVID CORMIE: Yes, that's the publicly available estimate that Minnesota Power has provided Manitoba Hydro.

MR. BOB PETERS: And can you tell the Board if that cost estimate includes an amount on account of contingency?

(BRIEF PAUSE)

MR. DAVID CORMIE: Yes, Mr. Peters, that includes the -- the contingency and that's the amount that's included in the facility's construction agreement.

MR. BOB PETERS: Turning to tab -- to page 197, Mr. Cormie, MGF in their report has benchmarked the costs of the Great Northern transmission line against Manitoba Hydro's Minnesota -- Manitoba/Minnesota transmission project, as well as a -- an industry benchmark.

Do you see that?

MR. DAVID CORMIE: Yes, I see that.

MR. BOB PETERS: And likewise, on page 202 of Board counsels' book of documents, we see just on the screen in front of you, based on the metrics the Great Northern transmission line project is significantly higher than those project metrics seen for other projects; correct?

MR. DAVID CORMIE: Yes.

MR. BOB PETERS: And can you indicate to the Board at this time, why Manitoba Hydro's costs appear to be significantly higher than metrics for other projects that are benchmarked?

MR. DAVID CORMIE: Were you asking me whether Manitoba Hydro's project or Minnesota Power's projects?

MR. BOB PETERS: I have your clarification. I'm going to -- I'm talking about the Great Northern transmission line project. And you correctly are reminding me that that's Minnesota Power's project?

MR. DAVID CORMIE: Yes.

MR. BOB PETERS: So in terms of the information that Manitoba Hydro has provided and in terms of its comparability to other transmission lines, is Manitoba Hydro able to provide an answer as to why the cost, according to MGF, for the Great Northern transmission line appear higher than other similar industry projects?

MR. DAVID CORMIE: Yes, I can provide that. Minnesota Power always intended their estimate to be conservative and at the time the estimate was prepared it -- like, with the MMTP project, they did not have a final route, and they recognized that there was a long period of time between the time and the estimate was prepared and the in-service date.

And so they deliberately chose a -- a conservative number for the purposes of the forecast. And we believe now that -- that that -- that number is -- still believe that that number is conservative. Minnesota Power has yet to finalize some of its contract costs. And once those contract costs are finalized, we will be updating the budget to recognize market prices, but as of now we're comfortable to have a cushion in our -- our budget and we're -- we believe that we'll leave -- leave that there -- Minnesota Power will leave that there until they're more confident in what their actual costs will be.

MR. BOB PETERS: When you say "conservative," Mr. Cormie, you mean that the Minnesota Power's costs for the Great Northern transmission line are on the high side of what will actually come in?

MR. DAVID CORMIE: Yes. To date, the contracts that have been let by Minnesota Power have been as forecast or underforecasts. But as I indicated in my direct testimony this morning, only about 10 percent of the cost of the projects have been spent to date and we believe it's premature to assume that we can rely on that in order to lower the estimate. Better to be underforecast than to be caught short.

MR. BOB PETERS: I'm not sure I -- I agree with your -- your terminology, Mr. Cormie. "Better to be underforecast," what you mean to say is better to have your forecast showing a higher price than what you expect will actually come in.

MR. DAVID CORMIE: Yes, unfortunately, Minnesota Power doesn't use the probability based. They haven't given us a probability associated with their forecast. They've indicated it is a conservative forecast. So they -- they believe and our -- our analysis of their estimate is that -- that it is probably conservative and, with time, we will get a revised estimate that will be more -- more likely to be closer to what we actually expect to spend.

MR. BOB PETERS: Mr. Cormie, while the revisions, if any, to the in-service costs of that budget are considered confidential in these proceedings, Manitoba Hydro's public position is that if the capital costs of the Great Northern transmission line exceed $1 billion, then Manitoba Hydro will not proceed.

You're aware of that?

MR. DAVID CORMIE: I think you're referring to my testimony at NFAT where I indicated that if the cost of the Great Northern line came in at $1 billion, the project would not be viable. We are not anywhere close to spending $1 billion on the Great Northern transmission line.

MR. BOB PETERS: And -- and Mr. Cormie, I was quoting you put on page 204 of Board counsels' book of documents, it was from the 2015 General Rate Application, but other than that, I'll accept your answer, if that's satisfactory to you, sir.

MR. DAVID CORMIE: Yes, I stand corrected.

MR. BOB PETERS: Now, Mr. Cormie, in September of 2016 the Boston Consulting Group was asked to review the business case on the Great Northern transmission line.

You're aware of that?

MR. DAVID CORMIE: Yes, we contracted with them to help us make a final decision -- commitment to construct the line in the fall of 2016, and -- and given that they had worked through the summer for our board on the Keeyask project, they were well capable of providing that service.

MR. BOB PETERS: And on page 231 of Board counsels' book of documents, we see the engagement letter; correct?

MR. DAVID CORMIE: Yes, I see that.

MR. BOB PETERS: And on page 235 of Board counsels' book of documents one (1) of the benefits associated with the Great Northern transmission line project, Mr. Cormie, is Manitoba Hydro's access to the Wisconsin markets; correct?

MR. DAVID CORMIE: Yes, the --

MR. BOB PETERS: And -- I'm sorry.

MR. DAVID CORMIE: When we requested transmission service associated with the Great Northern transmission line, MISO provided us access -- additional 500 megawatts of export access into Wisconsin as -- as part of our transmission request.

MR. BOB PETERS: And from your evidence this morning, the suggestion was that Manitoba Hydro should be able to extract higher export prices if they ship energy into Wisconsin?

MR. DAVID CORMIE: What I indicated in my testimony was that in the bilateral market for the long -- sale of long-term firm power, Wisconsin is a higher cost market than Minnesota and so it creates opportunities for Manitoba Hydro to sell long-term firm power over the firm transmission associated with the -- with the project. So those are the opportunities.

Spot market electricity is priced at the border, whether it goes into Wisconsin or Minnesota. So the opportunity market doesn't make any difference, but from a bilateral perspective, it -- it provides more -- a larger customer base.

MR. BOB PETERS: Mr. Cormie, have the higher prices for bilateral agreements in Wisconsin been reflected in Manitoba Hydro's export revenue forecast?

MR. DAVID CORMIE: There are two (2) contracts in the export revenue forecast for the sale of firm power to Wisconsin public service. One that we're currently engaged in delivering to, and one that commences in 2021 as a result of the construction of Keeyask. Those are very attractive prices for Manitoba Hydro.

MR. BOB PETERS: Those prices are included in the export price forecast?

MR. DAVID CORMIE: Yes.

MR. BOB PETERS: And so are there any additional bilateral agreements in Wisconsin included in the export forecast other than the two (2) that you've referenced?

MR. DAVID CORMIE: No, we're -- we're building -- building the market in Wisconsin as we speak.

MR. BOB PETERS: Mr. Cormie, on your slide, which I think is part of Manitoba Hydro Exhibit 120, I believe it's on page 117, if I've got this right. I don't.

I'm looking for the Great Northern transmission line project, Mr. Cormie, and your slide number 3. I don't know if you gave that as a separate -- a separate PDF. It would relate to the...

(BRIEF PAUSE)

MR. BOB PETERS: Perhaps 106, if we could try that page. All right, we are -- one more page forward I believe will be where we want to go.

MR. DAVID CORMIE: The US interconnection objectives?

MR. BOB PETERS: Yes.

MR. DAVID CORMIE: Yes.

MR. BOB PETERS: Thank you very much, Diana, with putting up with my searching.

On this page, this morning, Mr. Cormie, you talked about reducing import costs once the Great Northern and the Manitoba/Minnesota lines are constructed; correct?

MR. DAVID CORMIE: Yes, Mr. Peters.

MR. BOB PETERS: And that reduction in import costs occurs for what reason?

MR. DAVID CORMIE: It -- it occurs when we're importing. There is congestion between the MINNHUB price and the Manitoba border. And so prices at the Manitoba border are higher than if we were to buy that electricity in Minneapolis.

Now, you're build -- you're building a bigger transmission network, so, power can more easily flow from Minneapolis to the border, therefore, the price at the border is lower when we're purchasing. So import costs are reduced. And conversely, the same thing happens when we're exporting because you have now a larger transmission network delivering electricity in Minneapolis, the price at the MISO node, the pricing note at the border, goes up and approaches the price that you would receive at the market.

Right now there's about a -- on average, a 2 to 5 percent difference in those prices and so they'd be price improvement for exports and price reductions for imports which add value to all of Manitoba Hydro's exports and reduces the costs for all our reports.

MR. BOB PETERS: Has that 2 to five percent difference in the value that that spins off, Mr. Cormie, been included in Manitoba Hydro's export price forecasts?

MR. DAVID CORMIE: I don't believe so. I believe that we are still relying on the historical ratio between -- that exists on the existing interconnection. We have not yet reflected in the IFF the additional revenue that would be associated with that improvement.

MR. BOB PETERS: All right. On the bottom part of this page in front of us, the increased export capability, an extra 900 megawatts, has that been included in Manitoba Hydro's export price forecast?

MR. DAVID CORMIE: It's in the IFF because the export capability doesn't change the price, it just makes -- allows us to export more electricity rather than spill it when the existing transmission line is fully loaded.

MR. BOB PETERS: All right, thank you.

Mr. Cormie, I want to turn with you to the last subject that I have today is the SaskPower sale and transmission line.

The matter you spoke to this morning as well, sir?

MR. DAVID CORMIE: Yes.

MR. BOB PETERS: Currently, Manitoba Hydro has a 25 megawatt sale to SaskPower on the books from 2015 to 2022?

MR. DAVID CORMIE: That's correct.

MR. BOB PETERS: A seven (7) year contract, sir?

MR. DAVID CORMIE: I think it's six (6) years.

MR. BOB PETERS: Okay, and it's on existing transmission?

MR. DAVID CORMIE: Yes, it is.

MR. BOB PETERS: Is it also correct that Manitoba Hydro has a 500 megawatt term sheet with SaskPower?

MR. DAVID CORMIE: No, that is incorrect. We have a 500 megawatt Memorandum of Understanding that allows the companies to explore opportunities.

MR. BOB PETERS: And that Memorandum

of Understanding is that related to both energy, as well as transmission interconnections?

MR. DAVID CORMIE: Yes, it has quite a broad scope, including a lot of different activities, including the exporting of surplus electricity and the study of additional transmission facilities.

MR. BOB PETERS: It is, Mr. Cormie, for nonlegal terms, it's -- it's just a precursor to possible future agreements.

Would that be how you understand it?

MR. DAVID CORMIE: Yes. One (1) of the purposes of a Memorandum of Understanding is to define the scope of the discussions that take place between the Utilities and to create a confidential context so that we agree to share our confidential information and -- and allow those conversations to take place.

But there is non -- it's a nonbinding, nothing can happen under that agreement, except the study.

MR. BOB PETERS: Is this 500 -- sorry, is this 100 megawatts sale that you've spoken about with SaskPower between June of 2020 and May of 2040 part of that 500 megawatt Memorandum of Understanding?

MR. DAVID CORMIE: Yes, it's a child

of that process.

MR. BOB PETERS: I take it you're the father? Mr. Cormie, to complete the 100 megawatts sale, each Utility is responsible to construct the transmission in their respective provinces?

MR. DAVID CORMIE: That is correct.

MR. BOB PETERS: Does the power flow both ways on this transmission line?

MR. DAVID CORMIE: Contractually the power is only designed to be exported. The -- the power flow will be in both directions, depending upon the -- the -- the network flows a power at the time. So it -- it -- it is designed as an export line, it's not designed to provide any firm import capability into Manitoba.

MR. BOB PETERS: And on page 251 of Board counsels' sixth book of documents, the project cost, Mr. Cormie, is quantified at $57 million, perhaps now $56.5 million?

MR. DAVID CORMIE: Yes, that was our estimate in 2015. And I believe that estimate is under review, and the -- and the -- we expect an update in that in the next capital expenditure forecast.

MR. BOB PETERS: All right, thank you

for that. On page 253 of Board counsels' book of documents, would the Board be correct in understanding, Mr. Cormie, that Manitoba Hydro in 2015 conducted an economic evaluation of this sale?

MR. DAVID CORMIE: Yes, as part of the approval process for sales, something that outside of my scope of responsibility is an economic evaluation and that was done.

MR. BOB PETERS: And the economic evaluation was done on both a 100 and a 140 megawatt sale option?

MR. DAVID CORMIE: Yes, we offered SaskPower the option of taking an additional 40 megawatts, and so we had to be prepared for them to accept the -- the extra 40 megawatts, and so the valuation was done on that basis as well.

MR. BOB PETERS: And both options required new transmission lines?

MR. DAVID CORMIE: Yes.

MR. BOB PETERS: And the economic evaluation included both capacity and energy charges, Mr. Cormie?

MR. DAVID CORMIE: Yes.

MR. BOB PETERS: And the environmental attributes were transferred to SaskPower and included in the price?

MR. DAVID CORMIE: Yes.

MR. BOB PETERS: And we see on page 258 of the Board counsels' book of documents that Manitoba Hydro's evaluation or mini NFAT, or Needs For an Alternative review on this project, it looked at three (3) scenarios, sir?

MR. DAVID CORMIE: That is correct.

MR. BOB PETERS: Has Manitoba Hydro's executive committee, and Manitoba Hydro's Board of Directors, provided approvals for this, Mr. Midford or Mr. Cormie?

MR. DAVID CORMIE: Yes, these -- this sale agreement was approved by the Manitoba Hydro Electric Board.

MR. BOB PETERS: Was Manitoba Hydro required to obtain approval from the government of Manitoba to proceed with the transmission line and the sale agreement?

MR. DAVID CORMIE: All sales agreement that require the construction of capital projects requires approval by the province of Manitoba.

MR. BOB PETERS: And that approval is provided by way of the province borrowing money tp support the project?

MR. DAVID CORMIE: No, there'd be an Order in Council associated with the sale agreement.

MR. BOB PETERS: When does construction begin, Mr. Cormie?

(BRIEF PAUSE)

MR. DAVID CORMIE: I'm sorry, Mr. Peters, I didn't hear the question.

MR. BOB PETERS: I was asking when Manitoba Hydro will begin construction on the transmission line.

(BRIEF PAUSE)

MR. GLENN PENNER: After the CEC approval. We have the probably a year or maybe more to construct.

MR. BOB PETERS: Has the Clean Environment Commission process been established?

(BRIEF PAUSE)

MR. GLENN PENNER: We haven't submitted yet. So no, the dates have not been completely identified.

It's a Class 2. So typically Class 2 would not require a hearing, so there is time.

MR. BOB PETERS: On page 262 of Board counsels' book of documents, Daymark Energy advisors, who are probably in town right now and coming here tomorrow, have indicated -- and I thought, Mr. Cormie, you put that in one of your presentations, that Daymark concluded that it is in the best -- it is in the interest of Manitoba Hydro and its ratepayers to proceed with the project, correct?

MR. DAVID CORMIE: Yes. Daymark did a -- quite a robust review of the -- of the project, and came to the same conclusion that Manitoba Hydro did.

MR. BOB PETERS: And you say a robust review based on the report that you reviewed?

MR. DAVID CORMIE: No, it was based on an updated information of the report that -- that we referred to previously was done at the time the sale was recommended to the Manitoba Hydro Board. Daymark has re -- has reviewed it in the current context.

MR. BOB PETERS: Yes, and you said it was a robust review. So let's just make sure the Panel understands that Manitoba Hydro's initial review was back I believe in 2015, Mr. Cormie?

MR. DAVID CORMIE: Yes.

MR. BOB PETERS: And in 2015, Manitoba Hydro was making various assumptions and those assumptions have changed under current conditions?

MR. DAVID CORMIE: Yes. I think Manitoba Hydro's load forecast has changed. Our export price forecast has changed. And there been changes to the cost estimate of the project. And so we reflected all the up-to-date information, and provided that to Daymark for their analysis.

MR. BOB PETERS: All right. On page 263 there is indication that even if the project is delayed, Mr. Cormie, the power agreement provides for interim deliveries for most of the power on the existing transmission system.

Do you see that?

MR. DAVID CORMIE: Yes, I do.

MR. BOB PETERS: You spoke to that this morning and can you explain to the Panel for how long this agreement would remain valid if the project was delayed?

MR. DAVID CORMIE: As I indicated in my testimony this morning, the Utilities have allocated the existing transmission service available between Manitoba and Saskatchewan for other uses. For short-term purposes, they are willing to relax those uses in order to make available as much of the hundred megawatts of power as possible.

And in our conversations with Saskatchewan Power, the -- we believe that most, if not all, of the power can be delivered using interim arrangements and we have talked about a -- doing that for a year. We haven't talked about doing it for in perpetuity, but it -- it is something that we know that in order to meet the construction schedule that Manitoba Hydro has there will have to be a little bit of flexibility in the use of the existing transmission service. And -- and so far with the 2021 in-service date that Manitoba Hydro is projecting, we're able to agree to -- to that interim service use.

MR. BOB PETERS: Thank you, Mr. Cormie. Before I close off the microphone, Mr. Chair, I would like the assistance I believe I'm going to pick on Mr. Midford.

To go back to Board counsel, page 144 with my last question, and it deals, Mr. Midford, with something we talked about on the Conawapa. We talked about Conawapa and -- and Bipole III, and the costs related to it.

In earlier portions of this hearing,

Mr. Midford, we have heard from Manitoba Hydro who has proposed a method to deal with what I'll call the sunk costs of the Conawapa generating station.

Are you generally familiar with that, sir?

(BRIEF PAUSE)

MR. LORNE MIDFORD: I'm not intimately involved in that, Mr. Peters.

MR. BOB PETERS: No and I -- I greatly appreciate that. Manitoba Hydro has put before this Board a future proposal as to how Manitoba Hydro wants to deal with the costs related to Conawapa.

Would you -- are you generally aware that that's the case?

MR. DAVID CORMIE: Is that the amortization over thirty (30) years, Mr. Peters?

MR. BOB PETERS: Yes.

MR. DAVID CORMIE: Yes, I'm aware of those.

MR. BOB PETERS: And -- and my only question, Mr. Cormie, and it may result in an undertaking is that we heard related to Bipole III that the costs that were previously attributed to

Conawapa were going to be brought over to Bipole III and not charged through on Conawapa.

Do you remember hearing that this afternoon?

MR. DAVID CORMIE: Yes, I remember the discussion.

MR. BOB PETERS: And so we would like confirmation, please, that the road costs that are attributable to Conawapa are not included in the $380 million that Manitoba Hydro wants to amortize over the thirty (30) years.

Could you take that as an undertaking and find somebody on the revenue requirement panel to assist you with that?

MR. DAVID CORMIE: Yes, we will -- we will undertake to determine what those Conawapa road costs are and how they're being handled.

MR. BOB PETERS: That would be satisfactory if your counsel agrees and I thank you for that.

MR. DAVID CORMIE: Okay.

--- UNDERTAKING NO. 59: Manitoba Hydro to provide confirmation that the road costs that are

attributable to Conawapa
are not included in the
$380 million that Manitoba
Hydro wants to amortize
over the thirty (30) years

MR. BOB PETERS: Mr. Chair, it's been a long day, and I've contributed to the -- the duration. So I want to thank the Board Panel for their indulgence. I also want to thank the witnesses from Manitoba Hydro for their responses to my questions.

I will be turning the microphone over in the morning to Dr. Williams, but only after counsel for the General Service Small, General Service Medium and KAP have their fifteen (15) minutes of questions of this panel first thing at nine o'clock tomorrow.

After the Consumers Coalition will be -- the Consumers Coalition is estimating approximately no more than forty-five (45) minutes and likewise, Manitoba Industrial Power Users group is estimating approximate forty-five (45) minutes.

So the in-camera session would begin tomorrow from 11:00 till perhaps as late as 12:30

tomorrow and we should be relatively on track to hear from Daymark on the SaskPower matter which we expect will not take the balance of the day as long as it has been today.

THE CHAIRPERSON: Thank you all. It's been a long day. Thank you very much and we'll adjourn until nine o'clock tomorrow morning.

(PANEL RETIRES)

--- Upon adjourning at 6:26 p.m.

Certified Correct,

Tories open to private-sector Hydro deals

WS

√f p 5

NOV 13 2006

ROCHELLE SQUIRES
Legislature Reporter

A Tory government would consider involving the private sector in financing and building more hydroelectric generating stations in Manitoba.

Opposition leader Hugh McFadyen said his party will be conducting a rigorous analysis into the public-private partnerships (P3s) funding model as a way to expand hydro capacity in the province.

"We would look at involving the private sector to finance hydro projects, much the way they do in B.C. and Ontario and other provinces," said McFadyen. "(If elected), we would adopt a pragmatic approach, and if we thought there was a benefit to consumers we would adopt it. If that case wasn't made, then we'd stick with traditional financing models."

The issue will undoubtedly be fiercely debated in the next provincial election.

The NDP government, still seething over the privatization of Manitoba Telecom Services Inc. by former Tory premier Gary Filmon, said McFadyen's ploy to use private money to expand Manitoba Hydro is a stepping stone toward selling off the utility.

Strong rating

"It's a back-door route to privatization," said Finance Minister Greg Selinger.

The minister said his government won't consider public-private partnerships to expand the utility because it's cheaper to use public dollars, not private money.

"It costs more money because the borrowing costs are higher. Our position, with our strong credit rating, is that nobody has been able to beat our rates," said Selinger.

Selinger said the utility must remain under the control of government, not a private board.

"The private sector would maximize shareholder value at the expense of the consumers of the service," he said.

McFadyen said the NDP government is being hypocritical because it used the P3 model to develop wind power.

He also denied any intention of privatizing Manitoba Hydro.

"We're not going to sell off Manitoba Hydro. MTS was a completely different case," said McFadyen. "We would never consider selling Manitoba Hydro. There's no reason to privatize a monopoly."

Private-public partnerships have flourished across the country as governments are finding them to be viable alternatives to borrowing for capital projects.

A 300-bed hospital in British Columbia, a courthouse in Calgary and a major highway in New Brunswick are all being built using a mix of private and public dollars.

Adrienne Batra, provincial director for the Canadian Taxpayers' Federation, said Manitoba's high debt is just cause for examining the P3 model further.

"The province should establish a long-term policy that would ensure core services are paid for without borrowing millions of dollars and adding to the debt," said Batra.

2.0 NEED AND ALTERNATIVES

2.1 INTRODUCTION

Manitoba Hydro is under a statutory obligation to ensure the availability of a supply of power adequate to meet the needs of the Province. Without improvement, Manitoba's system is extremely vulnerable to weather or other emergency events which could interrupt the use of either the existing Bipoles I and II high voltage direct current (HVdc) lines located on the Interlake corridor or the single southern converter station (Dorsey). This chapter describes the urgent need to ensure the reliability and security of Manitoba's power supply and reviews the various alternatives for meeting that need.

In arriving at the conclusion that the Bipole III Project is the best alternative for meeting the province's reliability requirements, the chapter considers and analyzes the following questions:

- Why is the Project needed and what load serving requirements will it have to meet in order to sufficiently enhance system reliability?
- What options aside from new north-south transmission are available for addressing system reliability and what criteria were used to evaluate such options?
- Given that the construction of new north-south transmission has been determined to be the best reliability option, what alternative means of transmission can be built in order to carry power from the north to the south?

The chapter identifies that the best solution to meet the reliability needs of the Province is a new overhead north-south HVdc transmission line. Alternative routes for the transmission line are considered in Chapter 7.

2.2 NEED FOR AND SIZE OF THE PROJECT

2.2.1 Overview of Manitoba Hydro System Reliability Issues

Manitoba is heavily reliant on hydroelectricity, approximately 70%[1] of which is generated in plants in northern Manitoba in the form of alternating current (ac). This power is fed into the northern ac transmission system which is known as the Northern Collector System. In order to supply southern Manitoba today, power in the Northern Collector System must be converted from ac to HVdc for transmission over the exceptionally long distances to southern Manitoba, and then re-converted to ac form in southern Manitoba for transmission to customers via the Southern ac System.

At present, the overall Manitoba Hydro system depends on two converter stations in the north (Radisson and Henday), two HVdc lines (Bipoles I and II) running south along the same Interlake corridor, and the single Dorsey converter station in the south. The single Interlake corridor carries about 70% of Manitoba's entire generation supply. Manitoba is the only system in the world with such a concentration (of percentage) of supply along one corridor and in one converter station.

Manitoba's HVdc system is extremely vulnerable to weather or other events which could damage the Bipole I and II lines in the Interlake Corridor or Dorsey Station. The potential consequences of such an outage of the existing HVdc transmission system are exacerbated by the very long estimated repair times. Wide front windstorm, fire, or tornado damage at Dorsey Station could cause an outage that shuts down the HVdc system for up to three years because of the time required to repair or replace equipment of such complexity. The duration of a similar outage of the Bipoles I and II lines, although not as severe and dire as a failure at Dorsey Station, could still easily cause an outage of six to eight weeks.

In the event of an extended HVdc outage, supply would be restricted to the generation connected to the ac system and the possible imports on the ac interconnections with the United States and neighbouring provinces. Such a restricted supply of power would be significantly inadequate to meet provincial demand, particularly in the winter, and could necessitate rotating blackouts for months. The potential shortfall has been growing steadily over the years, as increased demands for power from new and existing customers have increased the system load requirement.

---

[1] The Northern Collector System generation totals 3570 MW, which is 70.9% of the total Manitoba Hydro hydroelectric generation of 5033 MW.

The potential effects of such an event present a risk that is unacceptable to Manitoba customers, particularly in the very cold months when the loss of power for extended periods could have serious effects on health, safety and security. The loss of Dorsey Station for up to three years could have a disastrous impact to the province and its economy.

The extensive rotating blackouts would leave affected neighbourhoods without power for extended stretches of time on a daily basis meaning that day to day requirements such as lighting, refrigeration, heating/cooling would be unavailable on a rotating schedule. Similarly, businesses would also be without power to operate their facilities forcing them to close during such outages, and causing business disruptions.

The types of events that could occur to put system reliability at risk in Manitoba include forest fires, fire at a converter station, weather events such as downburst/wide front winds, tornados and ice storms. The probability and potential duration associated with these potential catastrophic events is discussed in the following section.

2.2.2 Probability and Durations of a Catastrophic HVdc Outage

The potential of catastrophic failure of either the Bipole I and II lines or Dorsey Station due to fire and extreme weather events has been evaluated by Manitoba Hydro, in consultation with experts in the field.

Studies (Teshmont 2001) have shown that with respect to Dorsey Station, there is a 1 in 29 year probability of outage due to fire and a 1 in 200 year probability of outage due to wide front winds. While mitigation measures have been put in place, which partially address fire vulnerability at Dorsey, there is little that can reasonably be done to mitigate vulnerability to wind and other weather events. The same studies (Teshmont 2001) revealed that the probability of the loss of the Interlake corridor is 1 in 17 years from a tornado, 1 in 50 years from icing and 1 in 250 years from wide front winds.

Several "near-miss" experiences in Manitoba have highlighted the need for a major system reliability enhancement. Two examples are outlined below, each of which could easily have caused greater damage and led to more severe consequences.

Manitoba Hydro Wind Event, September 1996

On September 5, 1996 a downburst wind event caused the failure of 19 Bipole I and II transmission towers just two km north of Dorsey Station. Had this event occurred closer to Dorsey Station, it could have also taken down the Dorsey-Forbes 500 kV interconnection which would have in turn reduced the amount of power that could be imported from the United States. It took over four days to restore one HVdc line. Bipole I and II converters were then operated on this one line until the second dc line was repaired.

Photo 2.2-1: Damaged Towers of (TWG #1991) Bipole I and II Lines by Downburst Winds in 1996

Due to the time of year (September), the load was relatively low. Manitoba Hydro managed to serve the entire load during this event by relying heavily on arranged imports of up to 985 MW of power from the USA and neighbouring provinces, as well as by appealing to the public to reduce consumption. Had the event occurred just a month or two later in the year when load levels would have been higher, rotating blackouts would have been unavoidable.

Elie Tornado, June 2007

On June 22, 2007, a level 5 tornado (the strongest confirmed tornado in Canadian history) flattened buildings and the electrical infrastructure in the town of Elie just west of Winnipeg. Extensive damage caused by the tornado left thousands of customers without electricity until service was restored two days later. Damage to towns and communities from a separate storm system farther west was more severe, leaving many more thousands of customers without power for even greater periods.

Photo 2.2-2: Elie F5 Tornado and the Aftermath Damage

The Elie tornado was on the ground for about 35 minutes, and traveled a distance of approximately 5.5 kilometres (km). Damage occurred throughout a swath of land that reached widths of up to 300 meters. At their most intense, the tornado wind speeds were estimated to have reached between 420 and 510 km/h. An entire two-story home was swept off its foundation and tossed 75 feet in the air before rotating around the tornado and being obliterated.

Dorsey station is only 30 km north of Elie. A tornado of this or even lesser magnitude at Dorsey would have leveled the station, causing the kind of catastrophic failure discussed throughout this chapter.

2.2.3 Potential Load Shortfall and Required Size for Reliability Project

The chart set out below in Figure 2.2-1 depicts the available power supply and peak load in the event of loss of the Bipoles I and II transmission lines. With Wuskwatim generation in service, in the event of a catastrophic outage, the 2011/2012 system shortfall at winter peak is about 1400 MW, and will increase steadily with the growth in load to approximately 1500 MW by 2017 and 2000 MW by 2025, even after the 300 MW improvement associated with Riel sectionalization. The supply which would be available under such outage conditions is based on existing thermal generating capacity, generation connected to the ac system and the ability to import 900 MW of power from outside of Manitoba. The 1500 MW shortfall would be equivalent to the power demand of over 300,000 average residences based on an average peak demand of 5 kVA/household.

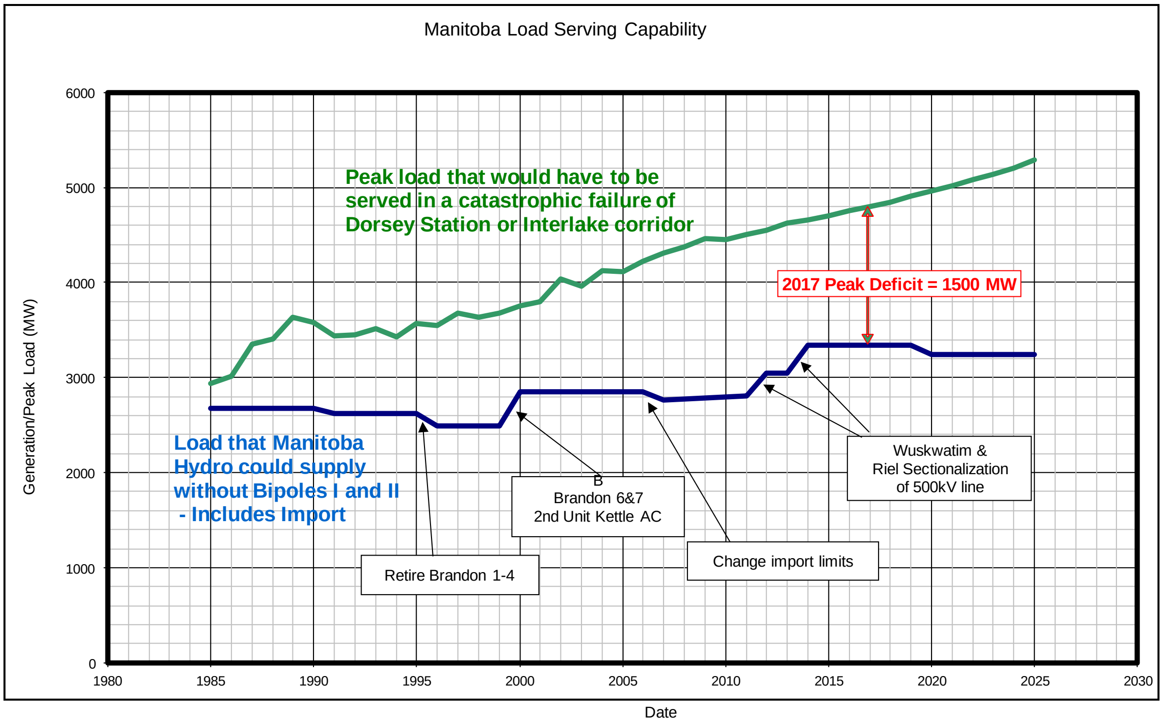

Figure 2.2-1: Load Serving Capability without Bipoles I & II

The deficit has been growing despite the various system improvements that have been made over the years, demonstrating the need for a reliability initiative that would address the deficit in full for a reasonable time frame in to the future.

Recognizing that the system is not always operating at peak load requirement, additional data must be considered to evaluate the consequences on a broader basis. Given that loads vary with both time of year and time of day, these variables must be taken into account when evaluating the loss of transmission capacity. Figure 2.2-2 depicts this analysis showing that in 2017/18, if Bipoles I and II were unavailable, Manitoba Hydro would be unable to meet provincial demand for approximately one third of the time during that period.

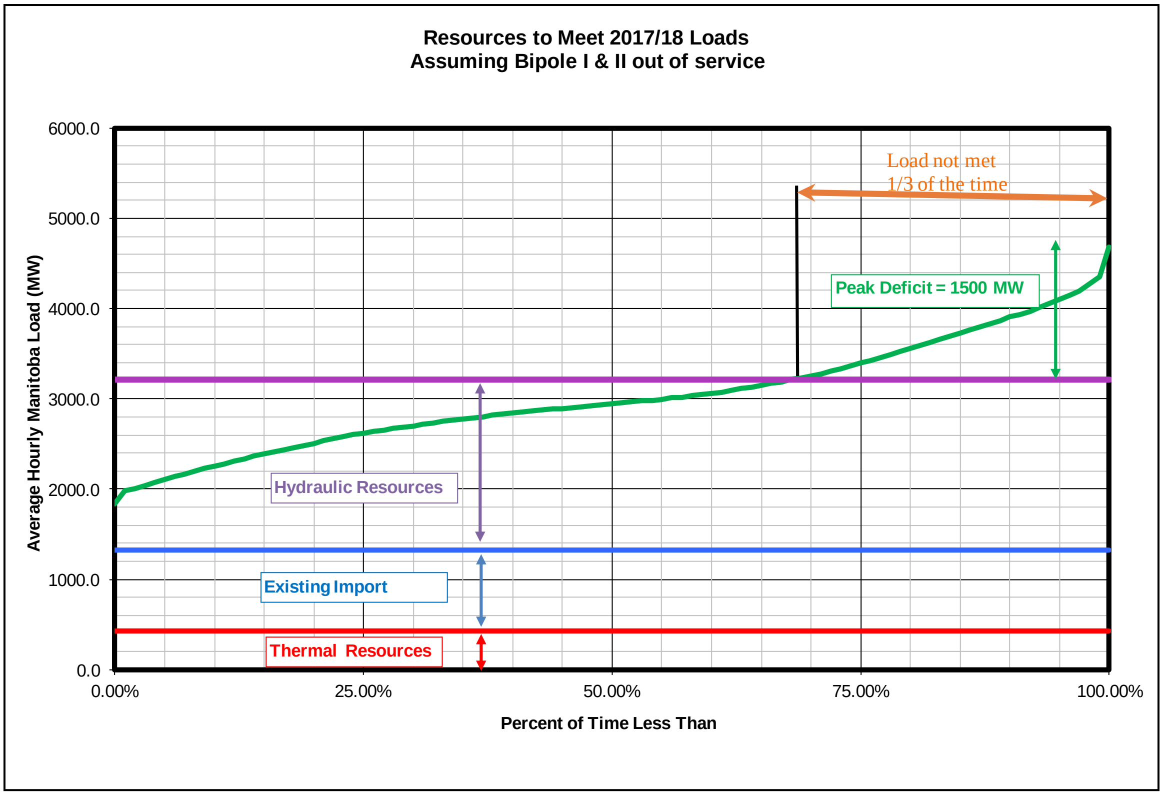

Figure 2.2-2: 2017/2018 Load Duration Curve for a Catastrophic Outage of HVdc

If an outage occurred in January 2017, be it at the Dorsey station or on the HVdc lines, as depicted on Figure 2.2-3, Manitoba Hydro would not be able to meet demand for 85% of the time during that month.

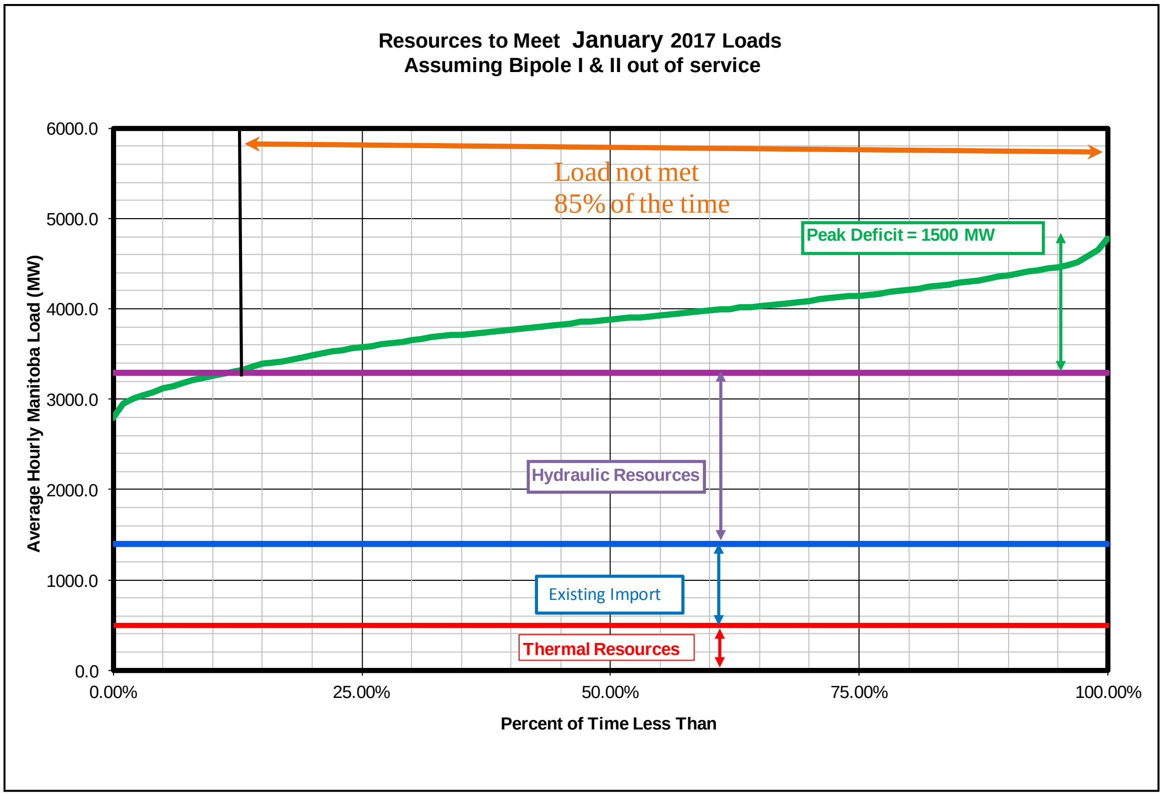

Figure 2.2-3: 2017 January Load Duration Curve for a Catastrophic Outage of HVdc

Given the significant consequences to Manitoba Hydro customers of an extended HVdc outage, the preferred reliability option should be able to minimize the unserved domestic load resulting from a catastrophic HVdc outage beyond the year it is put in service. A major factor considered in the selection of the 2000 MW Bipole III rating was the requirement to provide excess capacity beyond the 1500 MW deficit expected in 2017, the Bipole III in-service date, considering the extended time and outages required to add capacity in stages once the Bipole III is placed in service. A second important factor considered was compatibility with the existing system.

2.3 PROJECT ALTERNATIVES TO ADDRESS SYSTEM RELIABILITY

Alternatives to the project are the functionally different ways to meet the need for the Project and to achieve the Project's purpose. The following three alternative project options for enhancing the reliability of the Manitoba Hydro system were identified and evaluated:

1. The addition of 2000 MW of north-south HVdc transmission to continue to supply power from existing hydraulic generating sources in the north.
2. The addition of up to 2000 MW of gas turbines in southern Manitoba.
3. The addition of up to 1500 MW of new import tie lines to the United States (USA) to provide access to firm US generation, which is assumed to be comprised mainly of natural gas-fired generation, plus the addition of another 500 MW of natural gas-fired generation in southern Manitoba.

Other alternatives were considered to meet the Project's purpose, but were quickly ruled out as viable options. For example, some consideration was given to strengthening the existing HVdc transmission lines and converter stations to withstand higher stresses than those for which they were originally designed. While such work could lessen the vulnerability of the system, the probability of catastrophic outage associated with major events would still be too great to warrant strengthening as a solution on its own and, accordingly, it was not further evaluated. Staging of Bipole III was ruled out as being most costly due to the 1500 MW supply deficit and the minimal time between the initial stage and the completion stage.

2.3.1 Evaluation Criteria for Project Alternatives

Each of the three reliability improvement alternatives was planned and designed to meet the objective of continuing to serve Manitoba load in the event of an extended HVdc outage. The main criteria by which the project options were assessed are as follows:

1. *Project Cost* – The overall capital cost of each project alternative is a consideration for Manitoba Hydro in assessing project viability. Project cost was the main factor in the alternative evaluation.
2. *Implications to Manitoba Hydro during an extended catastrophic HVdc outage* – Given the potentially long repair times associated with potential catastrophic outages, each

project option was assessed having regard to the additional costs which would be incurred during such outages.

Implications to Manitoba Hydro during non-catastrophic outages and normal operation – The HVdc system currently has very little spare transmission capability (only about 300 MW). In the event of a more commonly occurring non-catastrophic HVdc outage such as a valve group or pole outage, this spare capacity is insufficient to transmit all available northern generation. Under this circumstance export curtailments or power imports may be necessary to meet load requirements. Accordingly, each reliability alternative has been evaluated for its ability to minimize additional costs and maximize value to Manitoba Hydro by providing coverage for planned/forced non-catastrophic HVdc outages.

Ability to facilitate future system expansion and enhance operational flexibility – Manitoba's growing domestic load will require future expansion of Manitoba Hydro's system generation capability. Over the last forty years, Manitoba Hydro has made huge investments in northern hydroelectric facilities and it is anticipated that future domestic load, as well as export requirements, will be met through additions to such infrastructure. Each of the three reliability options has also been assessed having regard to their ability to enhance operational flexibility as well as facilitate the choices available for future supply options.

Table 2.3-1 in Section 2.3.5 reviews the project alternatives relative to the project criteria. The discussion below reviews each project option studied and their respective evaluation.

2.3.2 Alternative 1 - Additional HVdc North-South Transmission

With respect to project cost, the construction of the proposed Bipole III is currently estimated at $3.28 billion in-service dollars. As noted in the previous section, the sizing of the Project is an important consideration. It has been sized for 2000 MW which will meet the projected reliability shortfall and enhance operational compatibility.

Long distance north-south transmission can be implemented using ac or dc transmission and the costs and operational attributes will vary according to the technology selected to carry out the project (see Section 2.4 below). Ultimately, the preferred means of HVdc overhead transmission is the most reliable, cost effective and technically viable option that also offers the greatest operational flexibility. The HVdc transmission line can be integrated into the Northern Collector System allowing operational flexibility of the three Bipole system. The addition of a third north-south HVdc line will increase efficiency of the north-south transmission system under normal operation, saving line losses of approximately 76 MW by splitting the generation from the Northern Collector System amongst three lines instead of two (Bipoles I and II).

Bipole III is the most attractive project alternative to protect the long-term supply of power, in that it continues to utilize existing northern hydraulic generation. The development of Bipole III also has the significant additional benefit of protecting Manitoba Hydro's options for future expansion of northern generating facilities both for domestic load and for export purposes, by adding additional transmission capacity into the system. While the primary driver of the project is system reliability, there is significant ancillary value to Manitoba Hydro in protecting and supporting the major investments it has made in northern generation facilities, as well as any future investments in northern hydroelectric resources. Moreover, failing to strengthen Manitoba Hydro's ability to transmit power from the north will reduce its attractiveness as a supply option to those export markets which Manitoba Hydro may in turn have to rely on for imports in an emergency situation.

2.3.3 Alternative 2 - Building Natural Gas-Fired Generation in Southern Manitoba

The second project alternative which has been assessed in the context of the potential load shortfall is the construction of approximately 1500 MW of natural gas-fired generation in southern Manitoba for 2017, and a further addition of 500 MW by the year 2025. The total cost of this gas turbine alternative has been estimated to be nearly $700 million (2010$) higher than that of the current estimate for the Bipole III Project on a present value basis.

The costs associated with this project alternative during any kind of outage would be significantly higher than the costs associated with transmission given that it would burn natural gas to generate power as opposed to utilizing northern hydraulic generation.

Gas capacity installed for system reliability would mostly be used for contingency situations; and accordingly, the capital investment will be used primarily as a "stand-by" source of power. The total project cost is comprised of the installation of gas turbines as well as the cost of ensuring a large firm gas supply on demand. The cost of the turbines themselves (2000 MW) is estimated to be $2.99 billion (2017$). Ensuring access to sudden and extensive demand for gas requires a firm gas supply for any given year throughout the 35-year planning horizon. An average cost of $181 million per year (in-service$) is required to secure a firm gas supply and consists primarily of a pipeline reservation fee with an additional cost for arrangements for the provision of fuel in the event that it is needed. It should be noted that the above cost of securing gas supply does not include the significant additional fuel costs that would be incurred when the gas turbines are operated during an outage.

In the event of a planned or unexpected outage, substantial operating, maintenance and fuel costs would be incurred for the natural gas-fired generation alternative. While idling in "stand-by" mode, gas turbines are required to run five percent of the time to ensure operational readiness. This in turn results in an additional annual fuel cost independent of turbine utilization.

During a catastrophic outage, the fuel, operating and maintenance costs associated with the supply of emergency power will be substantially higher for this option, and could be exacerbated by natural gas price volatility. There could also be delays associated with bringing the gas turbines from "stand-by" mode to full operational capacity. Use of non-renewable fossil fuels will increase the carbon foot print of this option in comparison to a transmission option linked to existing hydroelectric generation. In addition, this option would require the development of new transmission connections, with the possible exception of an installation near the Riel site, which would then require the construction of a gas pipeline to Riel.

Finally, this option significantly limits the potential for overall system development and enhancement given the lack of transmission connection to the major northern source of power from hydroelectric generating stations.

2.3.4 Alternative 3 - Importing Power

The third alternative involves the construction of a new high capacity transmission line between Winnipeg and Minneapolis, making it possible to import firm generation from a US supplier during an emergency. A 1500 MW interconnection of this nature is estimated to cost approximately $1.5 billion. In addition to this capital cost, this alternative requires firm power purchases in order to secure a reliable supply of import power, as well as 500 MW of natural gas-fired generation installed in Manitoba to meet growing load thereafter. A proxy for the cost of firm power purchases is the capital cost of adding 1500 MW of natural gas-fired generation in Manitoba, a standard proxy for new generation. Consequently, the total cost for the import alternative would consist of approximately $1.5 billion for building an interconnection and the capital cost of adding 2000 MW of natural gas-fired generation ($2.99 billion [in-service dollars]) plus operating costs. Accordingly, this option has the added cost of approximately $1.5 billion for building an interconnection but provides no additional benefits over the all-gas option.

The costs associated with this option during an outage will be similar or greater than the costs identified for the southern gas turbine alternative and would again expose Manitoba Hydro to natural gas price volatility.

A significant challenge associated with this project option is the need to engage US partners to construct the necessary generation and tie line facilities in the US. Building transmission outside of Manitoba and Canada is an unprecedented venture for Manitoba Hydro and would inherently have considerable risks involved. Given that Manitoba Hydro has been a supplier of significant amounts of firm clean energy to US customers for the past few decades, the concept of Manitoba Hydro requesting the US utilities to construct firm natural gas-fired generation for purchase by Manitoba Hydro would be a daunting request.

As with the gas supply option, this option significantly limits the potential for future opportunities for export sales as it does not enhance the transmission connection to the major northern source of hydroelectric power.

2.3.5 Recommended Alternative

The above discussion provides a description of the alternatives considered for improving Manitoba Hydro system reliability. Having regard to the criteria identified in Section 2.3.1, the Bipole III north-south transmission alternative is clearly the superior reliability solution at the least capital cost. In addition, it provides the greatest flexibility in operation and system expansion, with the least cost of emergency power during HVdc outages, catastrophic or otherwise. Furthermore, it is the only alternative that does not utilize energy generated from a non-renewable source and makes full utilization of the hydro-based generation system that Manitoba Hydro has developed over the past 50 years. The summary of the analysis of the three viable options having regard to the project criteria is set out below in.

Table 2.3-1: Evaluation Criteria for Project Alternatives

Objectives	Alternative 1 North-South dc Transmission	Alternative 2 Manitoba Natural Gas fired Generation	Alternative 3 Importing Power
Cost	Capital Cost (in-service dollars) $3.28 billion Fixed and variable annual cost $0.01 billion/yr	Capital cost amounts to $696 million more than Alternative 1 (Bipole III) on a present value basis Gas turbine installation cost $2.99 billion (in-service $) Fixed and variable annual cost $0.181 billion/year + variable costs	Capital Cost approximately $4.49 billion (in-service $) Annual costs subject to contract terms and variable costs
Savings/costs additional to the above	Reduction in transmission losses – approximately 26 M/year (2010$)	Annual cost of maintaining standby readiness	
Minimize unserved load during an extended HVdc outage	Meets reliability requirements until 2025. In the early years additional capacity available over the peak demand can reduce the import requirement costs	Meets reliability requirements until 2025 But heavily reliant on import from inception in 2017	Meets reliability requirements until 2025 Very high import dependency
Minimize costs to Manitoba Hydro during an extended HVdc outage	No additional costs	Significant fuel, operation and maintenance cost	Significant power purchase costs
Minimize costs to Manitoba Hydro during non-a catastrophic outage of HVdc	No additional costs	Fuel, operation and maintenance cost	Power purchase costs
Facilitate future system expansion and operational flexibility	Facilitates a reliability solution and an outlet for northern hydro development as soon as 2017	Provides only the reliability solution	Provides reliability solution and future potential for expansion of export access to US market

2.4 "ALTERNATIVE MEANS OF" CARRYING OUT THE PROJECT

Alternative means are the various technically and economically feasible ways the project can be implemented or carried out (CEAA 2007). Bipole III (overhead north-south dc transmission) was identified as the best alternative to meet the project need and purpose both economically and technically. A number of other means of carrying out the project were identified and evaluated. The alternative means identified included:

- ac versus dc transmission;
- Overhead lines versus underground option; and
- Overhead lines versus underwater option.

As discussed below, none of these alternative means were deemed to be viable options for this project. Alternative routes for the transmission line are reviewed in Chapter 7.

2.4.1 HVdc versus HVac Transmission

High voltage direct current (HVdc) transmission and high voltage alternating current (HVac) transmission are the two options for providing additional transmission capacity. The HVdc option requires a third transmission line from north to south that includes new converters at both ends. The HVac option would require new high voltage transformer stations and switchyards at both ends of the line and one or more stations at the intermediate points (voltage compensation) of the line for the transmission lengths in consideration.

The point to point distance from the Nelson River northern collector system to the load centers close to Winnipeg exceeds 800 km (Rudervall *et al* 2000; Seimens 2008; New England Power Service Company 1997).

The reason for development of HVdc systems was in part to deal with the excessive energy losses incurred over long distances when transmitting ac power. The use of dc transmission entails lower energy losses over distance but requires costly converter stations at each end of the system. Transmission losses on an HVdc transmission line are about 75% of the losses of an equivalent ac transmission line (New England Power Service Company 1997). Based on industry cost comparisons for HVdc and HVac transmission, HVdc transmission is most economical for distances exceeding on the average about 600 km (Rudervall *et al* 2000; Seimens 2008). Estimated loss savings with HVdc transmission can be more than 40 MW at full capacity utilization of the proposed transmission scheme.

A double circuit ac transmission on a single tower is considered to provide comparable capacity and availability to a bipolar HVdc transmission system. Due to their complexity, the capital costs for HVdc converter stations are higher than for high voltage ac substations. On the other hand, the transmission line costs are lower for HVdc transmission, given that only two sets of conductors are required as opposed to six for double circuit three phase ac transmission lines. Significantly smaller towers are required for HVdc versus ac. A 500 kV ac double circuit tower that provides adequate clearances and structural strength would be about 35% taller and much wider (Figure 2.4-1). One further major deterrent to using ac transmission is the need to connect the ac transmission line to the Northern Collector System. The greatest operational flexibility arises from a new transmission scheme that connects directly to this system, where power transfer between Bipoles I and II and the new scheme can be controlled without switching operations. This is easiest to achieve with HVdc due to its compatibility with Bipoles I and II.

In contrast, an ac line cannot readily be connected to the Northern Collector System without major and potentially very costly system changes. Since the existing north-south transmission is all HVdc, the Northern Collector System is isolated from (asynchronous to) the southern Manitoba interconnected ac system. This is unique to the Manitoba Hydro system and enables several special protection systems that enhance system stability, operability and export capability. A permanently connected ac line between the Northern Collector System and the south will disrupt this unique configuration. A north-south ac line permanently connected to the Northern Collector System will not be readily compatible with the existing system configuration without major reengineering of the existing protection and control schemes and the possible addition of new special protection systems (SPSs). An ac line left disconnected from the northern collector system will normally have the undesirable effect of delaying the process of power transfer to and from the ac transmission scheme, as it would involve switching generation onto the ac line and out of the northern collector system, and vice versa.

In essence, the analysis means that there are significant operating complexities and costly upgrades that would be required to make the ac transmission option viable. Even with such upgrades there will be switching delays in activating this transmission when required for system operations.

500kV 500kV Double Circuit

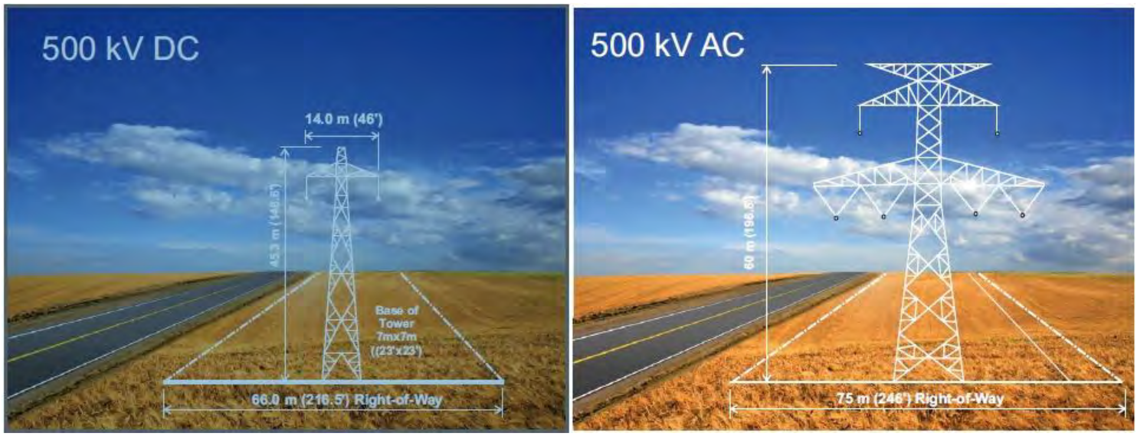

Figure 2.4-1: Typical Transmission Line Structures for 500kV 2000MW HVdc and AC Schemes

The double circuit ac line requires a significantly wider right-of-way (ROW), about 15% more than for HVdc as estimated by Manitoba Hydro. A 15% increase in ROW over a line length greater than 1300 km is significant, adding cost and requiring more land clearing (Table 2.4-1) to accommodate a 75 m wide ROW.

In summary, HVdc transmission is less expensive, less complex and provides the greatest operational flexibility with the existing Bipoles I and II. The ac transmission option is less desirable in the context of the reliability initiative; due to cost considerations and the additional complexity of operation it would impose on the Manitoba Hydro major transmission system as a whole.

2.4.2 Overhead Transmission Lines versus Underground or Submarine Cable Transmission

The point to point transmission distance from the northern collector system to the load centers close to Winnipeg exceeds 800 km. The actual transmission distance exceeds 1300 km for the west-side route that has been proposed. Overhead transmission is the most economical and technically mature technology for such long lengths of transmission. Underground ac cables require intermediate stations to control voltage along the line, which adds to the cost and operating complexity and reduces reliability. As a result, there is no bulk power transmission scheme in the world that uses underground ac cable technology for lines longer than 100 km in length.

Underground or underwater HVdc cables are rarely used where overhead transmission is technically viable. In fact, worldwide, there is no high power, long distance underground cable transmission; underwater dc cable transmission is used because it is the sole transmission choice for crossing large bodies of water and they are usually accessible to large ocean going cable laying ships. Underground or subsurface transmission at the 500 kV voltage level, even in favourable terrain conditions, is on average five to six times more costly than overhead transmission. Even if it were otherwise feasible, underground transmission requires a cleared right-of-way and does not eliminate concerns about the loss of vegetation and habitat, or about increased access (two of the principal concerns encountered with transmission lines in northern Manitoba) or disturbance to agricultural lands in southern Manitoba.

Underwater (submarine) cables laid in trenches in the lake bed of Lake Winnipeg have also recently been investigated conceptually as an alternative form of transmission for future transmission projects (Farlinger *et al* 2011).

A review panel consisting of multi disciplinary experts both within and external to Manitoba Hydro has investigated the potential use of the submarine or underground cables for long distance electricity transmission in Manitoba. The report was completed early this year and reviews the various potential routes, costs and performance issues associated with the application of these technologies to Manitoba (Farlinger *et al* 2011).

According to the above report, the current technology for cable transportation is limited to short cable lengths and therefore requires hundreds of splices (cable connections). It also identifies the life expectancy of underground and submarine cables as half of that of overhead lines. The failure rates are high (failure every 3 to 17 years). Repair times would be longer and costs would be higher considering the long winter months in Manitoba when Lake Winnipeg is ice covered. The report concludes that it is premature to consider submarine or underground cables as a means of delivering this project at this time.

2.4.3 Recommended Means

The above discussion provides a brief description of the alternative means considered for carrying out the preferred project of additional north-south transmission with overhead HVdc transmission being the recommended means. This option is by far the least cost alternative, is technically feasible, and provides excellent reliability. The comparison of the various north-south transmission options is set out below in Table 2.4-1.

Table 2.4-1: Comparison of North-South Transmission Options

	Overhead HVac	Overhead HVdc	Underground HVdc	Underwater Hvdc
Cost	Very high for the considered length of transmission	Least cost	5-6 times more than the HVdc	Highest
Feasibility	Feasible	Feasible	Feasible for short distances	Not currently feasible in Manitoba situation
Reliability	Generally technology offers excellent reliability However, for this application there is compromise due to operational complexities	Excellent reliability	Not as reliable due to frequent and long repair times, due to the many splices in U/G cables. Shorter life time than O/H lines Maintenance in winter months can be difficult	Not as reliable as even the U/G due to short cable pieces spliced together as demanded by the cable laying technology Maintenance in the winter months can be prohibitive

2.4.4 North-South Transmission Alternative Corridors

Once north-south HVdc overhead transmission was selected as the preferred means for addressing system reliability, several alternatives were considered in selecting a corridor to route the preferred transmission option. The geography of Manitoba essentially forms three corridors between northern and southern Manitoba: east of Lake Winnipeg, the Interlake Region, and west of Lakes Manitoba and Winnipegosis.

The eastern corridor had been under consideration early in the planning stages. However, a policy decision was made by the Provincial Government that the reliability project should not be routed within this corridor. A copy of the letter from the Minister responsible for Manitoba Hydro providing this policy direction to Manitoba Hydro is attached as Appendix 2A to this chapter.

The Interlake corridor is the location of the existing Bipoles I and II and is unacceptable as a location for Bipole III. In order to meet reliability criteria, physical separation from the existing major HVdc transmission facilities is required. Separation is the only effective way to reduce the risk of common outage of all three lines at the same time. Given the over concentration of transmission in the Interlake corridor, the third transmission line must be located within a corridor well separated from Bipoles I and II in order to obtain maximum reliability benefits (Teshmont 2006). As such a separation is not feasible within the Interlake corridor; this corridor was rejected for Bipole III routing.

As a consequence of the above analysis, the western corridor was selected for routing the Bipole III Project. Several studies have quantified the reduction in risk of common outage for the various routing options (Teshmont 2006). In general a significant improvement in reliability can be gained by the western routing option as compared to the Interlake corridor. Routing options within the western corridor are reviewed in Chapter 7.

2.5 SUMMARY OF RECOMMENDED PROJECT AND RATIONALE FOR SELECTION

The existing vulnerability of the Manitoba Hydro transmission system to extreme weather and other events which would result in an inability to serve a large portion of the Manitoba load over extended outage durations clearly justifies the need for the project. The over dependence on a single transmission right-of way in the Interlake or a single Dorsey converter station for transmitting about 70% of the hydroelectric generation in Manitoba to southern load centers has long been seen as unacceptable for reliably meeting the needs of Manitoba Hydro customers. Any extended loss of power of this magnitude, would have disastrous consequences for the Province of Manitoba and its residents.

- The recommended option to address the energy supply reliability of the Manitoba Hydro system is the 2000 MW Bipole III alternative. This is the most cost effective alternative that meets the entire supply shortfall in the event of an extended HVdc outage with minimal risk and the most effective operating flexibility. The Bipole III alternative is about $696 Million (2010 present value dollars) less costly than the natural gas-fired generation alternative.
- The 2000 MW Bipole III provides the required capacity to meet load in the event of an extended HVdc outage of Dorsey Station or the Interlake corridor. This option has minimal operating cost to Manitoba Hydro during such an outage, as it would continue to utilize the low cost northern hydraulic generation, as opposed to gas generation or imported power considered in the other alternatives (Manitoba Hydro 2011).
- Bipole III would also provide the much needed north-south spare transmission for normal day to day operation and provides significant savings in transmission losses. The estimated potential savings in losses are 76 MW at maximum generation

approximately amounting to 243 GWh/year, which can have a value of $26 million/year to Manitoba Hydro (Manitoba Hydro 2011).

- The availability of spare transmission also results in minimizing the cost of non-catastrophic outages of the HVdc system, by minimizing the curtailment of firm export power and/or the need for import to serve domestic load. The planned or forced non-catastrophic outages would result in significant additional operating costs for the gas or import alternatives (Manitoba Hydro 2011).
- Bipole III is the only alternative that facilitates reliable and economical system expansion for serving future load growth. Thus it has the most potential to meet reliability needs, as well as increases to domestic load and/or export requirements in future years with minimum cost. The gas or import options inhibit future participation in the export market which has historically enhanced Manitoba Hydro's ability to maintain low electricity rates.

2.6 CONCLUSION

A system reliability initiative, Bipole III is needed to provide a back-up transmission path, recognizing the existing vulnerability of Bipoles I and II, which share a common transmission line corridor and a single terminus at Dorsey Station. Based on both technical and economic feasibility, as well as environmental considerations, overhead high voltage direct current (HVdc) transmission is the best technology to provide the reliability and security of power for the province.

The process to select the route itself is described in greater detail in Chapter 7 of the EIS.

DECISION
of the
Manitoba Clean Environment Commission
On the Motion of the
Bipole III Coalition, Applicants
August 29, 2012

For the Applicant: Brian Meronek, Q.C.
Ivan Holloway
Intervenor: James Beddome
For the Respondent,
Manitoba Hydro: Doug Bedford

Decision

The Motion requesting an adjournment of the Hearings is dismissed.

Issue

The Applicant, by way of a motion made pursuant to Section 2.08 of the Clean Environment Commission *Process Guidelines Respecting Public Hearings*, requested an order directing the proponent to answer specific Information Requests, as well as an adjournment of the start of the Commission's public hearings to an unspecified date from the scheduled date of October 1, 2012.

Background

In December 2011, the Minister of Conservation issued a request that the Clean Environment Commission (CEC) hold public hearings on Manitoba Hydro's proposal to construct the Bipole III transmission line project.

In May 2012, the Bipole III Coalition was granted funding under the Participant Assistance Program (PAP) and, thus, became a registered participant for the CEC proceedings.

Commission's Authority

Subsection 6(8) of *The Environment Act* allows the Commission to make rules governing its procedure.

Section 2.08 of the Clean Environment Commission *Process Guidelines Respecting Public Hearings* provides:

> The Commission will accept motions respecting procedural matters from the Proponent and those designated as Participants.
>
> ………
>
> On hearing the motion, the Commission may allow, dismiss or adjourn the motion, in whole or in part, and with or without terms.

The Supreme Court of Canada reinforced this authority in a 1989 decision:

> As a general rule, these tribunals are considered to be masters in their own house. In the absence of specific rules laid down by statute or regulation, they control their own procedures subject to the proviso that they comply with the rules of fairness and, where they exercise judicial or quasi-judicial functions, the rules of natural justice. Adjournment of their proceedings is very much in their discretion[1]

Accordingly, the Commission does have the authority to decide whether or not to grant the requested adjournment.

The Manitoba Court of Queen's Bench, in *Candeias v. Manitoba (Residential Tenancies Commission)*, 2000 MBQB 216, considered the matter of a request for an adjournment of an administrative proceeding.

The judge quoted from a decision of the Supreme Court of Canada in identifying the principle to be followed by an administrative body in making such a decision:

> "… there is, as a general common law principle, a duty of procedural fairness lying on every public authority making an administrative decision which is not of a legislative nature and which affects the rights, privileges or interests of an individual: ...
>
> "The question, of course, is what the duty of procedural fairness may reasonably require of an authority in the way of specific procedural rights in a particular legislative and administrative context and what should be considered to be a breach of fairness in particular circumstances. ..."[2]

---

[2] *Cardinal et al. v. Director of Kent Institution* (1985), 16 Admin. L.R. 233 (S.C.C.)

Relief Sought

1. An Order or Direction of the CEC to Manitoba Hydro to respond to those Information Requests submitted to the CEC by the Coalition on July 19 and 20, 2012, as listed in attachment A to this Motion;

2. An adjournment of the Hearing scheduled to commence on October 1, 2012 to a date sufficient to enable the Information Requests to be answered; a second round of Information Requests to be submitted by the participants and answered by Manitoba Hydro; and, expert reports to be prepared in time before the commencement of the hearing; in accordance with the schedule, in attachment B to this Motion.

Applicant's Grounds

From Notice of Motion, filed August 8, 2012.

The Applicant's arguments focus on the fact that a number of its Information Requests were not submitted to the proponent for response. It argued that:

1. The Information Requests are relevant.

2. A review of the EIS demonstrates that the Information Requests are necessary in order to determine:

   a. The need at this time for Bipole III at all regardless of location;
   b. The reliability concerns alleged by Manitoba Hydro to be the motivating consideration behind Bipole III;
   c. Whether there are alternatives to the construction at this time of Bipole III in terms of environmental impact, cost and sustainable development specifically by relocating Bipole II to the La Verendrye S.S. (or perhaps the Riel S.S.).

3. All Information Requests are within the scope of the Terms of Reference to the CEC established by the Minister of Conservation on or about December 5, 2011.

4. All Information Requests directly relate to matters and issues specifically advanced by Manitoba Hydro in the EIS.

5. Natural justice requires that Information Requests which are clearly inside the Terms of Reference be allowed to be asked of the proponent without first having to be vetted and pre-approved by the CEC or its staff.

6. Natural justice requires that a tribunal not pre-judge the requirement for evidence without the proponent first putting the relevancy and admissibility of such evidence into question before the tribunal.

7. Environmental law recognizes that there be a meaningful need for and alternative to (NFAAT) assessment of a project in order for the tribunal to discharge its obligations in making recommendations to the Minister.

8. The proponent has put into question NFAAT in its EIS.

9. The timing of the receipt of IR responses; the need for a second round of IRs and responses thereto; and the ability of the Coalition's experts to adequately review the responses and prepare their report all militate in favour of an adjournment of approximately two months.

10. The state of the Record is inadequate to permit the hearing to commence on October 1, 2012 as scheduled.

11. There is nothing on the record submitted by Manitoba Hydro which would require the hearing to be held on October 1, 2012.

Proponent's Response

From Response of Manitoba Hydro, filed August 13, 2012.

According to the Brief filed by the Bipole III Coalition, it no longer seeks answers to a number of the IRs it submitted and has answers to others it submitted because they were duplicative of questions asked by other participants which were sent to Manitoba Hydro and which have been answered by Manitoba Hydro. With respect to the residual questions, to date, unanswered because they were found to be out of scope, Manitoba Hydro responds as follows.

1. The Terms of Reference given to the CEC by the Minister of Conservation do not direct the CEC to determine if there is a less costly way for Manitoba Hydro to meet, through existing facilities, its need to improve reliability. Questions seeking data or reports or alternative spreadsheet modeling intended to assist in determining the foregoing are out of scope for this hearing.

2. The Terms of Reference do not ask the CEC to determine whether Bipole III has to be built "at this time". Accordingly, questions that seek data or reports or alternative spreadsheet modeling intended to assist in proving that the Bipole III Project is not needed "at this time" are out of scope for this hearing.

3. While acknowledging that the EIS does have a chapter explaining the need for the Project and alternatives to it, the proponent is of the view that the Minister of Conservation, in his request that the EIS be "reviewed", did not intend that the CEC investigate whether Bipole III is needed "at this time" or whether there are cheaper, better alternatives.

4. Courts and tribunals are entitled to set aside, in summary fashion, documents filed with them that do not follow prescribed procedures or which are, on their face, out of scope. Not every decision made by every decision maker must necessarily be accompanied by 'notice' and 'an opportunity to be heard'. In any event, to be practical, the Bipole III Coalition is going to be heard on the issues raised in its Motion, notwithstanding that it is in effect "appealing" a decision to the CEC that it has already made.

Other Participants

Mr. Beddome of the Green Party of Manitoba spoke in support of the motion.

CEC Findings

The members of the Commission have carefully reviewed the written briefs filed by the applicant and by the proponent in response. We have also considered the oral arguments presented.

The applicant asked for two different remedies in this motion:

- an order directing the proponent to respond to specific Information Requests submitted by the applicant; and
- an adjournment of the commencement of the hearing to a date sufficient to enable the Information Requests to be answered; a second round of Information Requests to be submitted and answered; and, expert reports to be prepared in time before the commencement of the hearing.

In addressing the first remedy, counsel for the applicant argued that all of the information requests in question are relevant, that they relate directly to matters in regard to the "needs for and alternatives to" the project (NFAAT). Counsel argued that the Terms of Reference issued to the Clean Environment Commission are very clear that NFAAT issues are to be reviewed in the public hearings.

The applicant dismissed suggestions by the proponent's counsel that the Commission seek a clarification of the Terms of Reference from the Minister. The applicant argued that there is no ambiguity in the terms of reference and, thus, no need for clarification.

In his response, counsel for Manitoba Hydro argued that the Minister did not specifically ask the Commission to investigate matters relating to NFAAT. He argued further that, if the panel were to engage in considering NFAAT matters, it would be at the expense of environmental issues, which he stated is our area of expertise.

The conflicting positions presented on this matter made it clear to the panel that a clear and wide divide exists among parties on the matter of reviewing NFAAT matters during the hearings.

While an NFAAT consideration is a requirement of environmental reviews conducted under the federal *Canadian Environmental Assessment Act,* it is not required by provincial statute and has not been a part of provincial reviews.

The one exception to this was the review process for the two Wuskwatim projects – the generating station and the transmission line. Rather than subject the projects to two separate and potentially lengthy reviews, it was decided to have a joint Clean Environment Commission-Public Utilities Board review, with members of both bodies sitting on the review panel. The Terms of Reference issued by the Minister specifically stipulated reviews of both NFAAT and environmental matters.

Wuskwatim was a distinct, one-time process. The Clean Environment Commission, in stand-alone hearings, has not undertaken NFAAT reviews.

In order to resolve this divide among the parties, the panel elected to write to the Minister seeking clarification as to his intent in regard to the Commission's review of NFAAT, as it relates to Bipole III.

The Minister has responded that it was not his intention that we engage in an NFAAT review.

Accordingly, the first remedy sought is not granted.

The second remedy sought by this applicant asked for an adjournment of sufficient time to allow for the completion, receipt and analysis of certain information. Co-counsel for the applicant, in arguing this matter, spoke of the large scale of the project, the large amount of information filed and the tight timeframes for the participants to prepare prior to the commencement of the hearings.

This argument shares some elements of that put forward by the Consumers' Association of Canada.

The panel recognizes that the Bipole project is not insignificant in its size and in the amount and scope of the materials provided. The panel also recognizes that there is much work involved in preparing for the hearings.

However, the amount of time for the Bipole proceedings is not out of line when compared with other recent CEC hearings. For the Wuskwatim hearings, the period from the filing of the EIS by the proponent to the start of the hearings was eleven months; for the Floodway Expansion, it was six months. For Bipole III, the proposed start date for the hearings is ten months after the filing of the EIS.

During the course of the hearings, the applicant, along with all of the other participants, will be given every reasonable opportunity to pose questions to the proponent. It will be incumbent on the proponent to respond adequately to all such relevant questions. There is no fixed end-date to the hearings.

Further, it is open to participants to argue against the issuance of an environmental license or to argue that any license should be subject to conditions.

If the Commission concludes, after hearing all of the evidence from the proponent and the various participants, that there remain unanswered, relevant questions, the Commission can emphasize such conclusions in its final report.

In such a case, the Commission would have the authority and the mandate to consider a number of alternatives available in making recommendations to the Minister.

The decision in regard to the second remedy is to dismiss the application and to confirm that the hearings will commence on October 1, 2012.

The Commission has set out a process that will allow testing by participants of the EIS filed by the proponent and is confident that the concerns expressed by the applicant can be addressed through the hearing process.

The Commission remains of the view that the process, upon which we have embarked, balances the needs of all of the parties to have an efficient, fair and transparent process, and allows sufficient opportunity to test the relevant information.

Disposition

On the application for an Order or Direction of the CEC to Manitoba Hydro to respond to those Information Requests submitted to the CEC by the Coalition on July 19 and 20, 2012, as listed in attachment A to this Motion, the decision is to dismiss; and

On the application for an adjournment of the Hearing scheduled to commence on October 1, 2012 to a date sufficient to enable the Information Requests to be answered; a second round of Information Requests to be submitted by the participants and answered by Manitoba Hydro; and, expert reports to be prepared in time before the commencement of the hearing; in accordance with the schedule, in attachment B to this Motion, the decision is to dismiss.

Conclusion

Given the decision on this application, the Commission confirms that the hearings will commence on October 1, 2012.

DATED this 29th day of August, 2012.

August 20, 2012

Honourable Gord Mackintosh
Minister of Conservation
Room 330 Legislative Building
Winnipeg, MB R3C 0V8

Dear Minister:

I am writing to seek clarification with respect to the Terms of Reference for the Manitoba Hydro Bipole III Transmission Line Project, specifically in regard to the review of the "need for and alternatives to" the project (NFAAT).

On August 16, 2012, the Commission considered motions presented by registered-Participant groups in advance of the hearings. During the presentation of positions, it became apparent that a clear and wide divide exists among Parties as to how deeply the Clean Environment Commission should go in reviewing NFAAT matters during the hearings.

On the one side, the Proponent, Manitoba Hydro, is of the view that, since the Terms of Reference issued to the Commission in December 2011 do not specifically identify a review of NFAAT, the Commission has no authority to enter into such considerations.

On the other side, at least two Participants are of the view that the NFAAT review should be a full PUB-style deliberation, considering whether or not the project is necessary.

Both sides may be looking to the Wuskwatim review in 2004 as an example.

The Wuskwatim project involved two separate, but obviously connected, proposals: the generating station and a transmission line. In an effort to streamline the regulatory process, it was decided that, rather than subject the projects to separate and potentially lengthy reviews by both the Public Utilities Board and the Clean Environment

Manitoba

Commission, the two would be combined into one proceeding. To that end, two members of the PUB were cross-appointed to the CEC. Terms of Reference were issued by the Minister of Conservation, which specifically addressed both sides of the review.

The Participants may be of the view that the Wuskwatim precedent is the “new normal”, calling for a full-NFAAT review; while Hydro takes the view that, in the absence of specific directions on NFAAT as in Wuskwatim, there should be no such review at all.

While an NFAAT consideration is a requirement of environmental reviews conducted under the federal *Canadian Environmental Assessment Act,* it has not been a part of provincial reviews. Except for the Wuskwatim example, the Commission, in past proceedings, has not undertaken NFAAT reviews.

The Panel is caught in a dilemma on this issue. In order to resolve this, we ask that you clarify your intent in regard to the Commission’s review of NFAAT, as it relates to Bipole III.

Minister, time is of the essence. Without resolution of this matter in short order, there could be significant impacts on the scheduled hearing and its timely completion. It will be necessary to issue decisions on the August 16 motions by the end of this week.

Sincerely,

AUG 23 2012

August 23, 2012

Mr. Terry Sargeant
Chair
Clean Environment Commission
305-155 Carlton St.
Winnipeg MB R3C 3H8

Dear Mr. Sargeant:

Thank you for your August 21, 2012 letter requesting clarification of the Terms of Reference for the CEC's review of Manitoba Hydro's Bipole III Transmission Line Project. In response to your specific question about a Needs For And Alternatives To (NFAAT) review, the Terms of Reference, which were issued in December 2011, do not include instruction for the CEC to conduct an NFAAT.

I trust this clarifies this matter.

Yours sincerely,

Gord Mackintosh
Minister

CC. Fred Meier
Dan McInnis
Tracey Braun

Tab 28

Bipole III, Keeyask and Tie-Line review

September 19, 2016

The Boston Consulting Group

Exhibit 1: Assessment of complex program of three projects

Each with standalone objectives and integrated benefits

	Bipole III	Keeyask	Tie-line[1]
	Endorsed on reliability need	*Preferred generation option*	*Acceleration opportunity*
Project objective	**Mitigate longstanding system reliability risk** • Ensure reliability against losing Bipole I & II lines or Dorsey converter station	**Satisfy future Manitoba energy need** • Meet future domestic energy need • Leverage Manitoba's clean hydro resource	**Secure cost-effective dependable energy** • Reduce future need for domestic generation • Expand market access in MISO (MN & WI)
Secondary considerations	**Strengthen physical transmission capability** • Additional peak capacity (enabling new generation) • Redundancy for maintenance	**Leverage resource attributes to cover part of costs through export** • "New hydro" to satisfy US tie-line requirement • Leverage increased peak capacity from Bipole III	**Increase value of domestic resources** • Reduce Bipole corridor reliability requirement • Improve Keeyask value generation potential

1. Tie-line = MMTP plus GNTL

Exhibit 2: Core questions being addressed in this effort

1. **Were the original decisions the right ones?**

2. **Is there further downside risk?**

3. **Can they be stopped or paused without undue cost or risk?**

Exhibit 3: Summary of key messages

1 Original decision on Bipole III justifiable but Keeyask (in hindsight) a less prudent decision

- Bipole III East was lowest-cost option to address longstanding, untenable reliability risk but the Province directed Hydro not to consider it
  - Of remaining options, Bipole III West lowest cost vs. All gas and Import + gas
- Keeyask (with US Tie-line) long-run economics attractive on paper, but financial and execution risks not fully considered
  - Rationale existed for accelerating Keeyask, e.g.: sustainable energy solution that capitalizes on expiring export opportunity
  - However, several factors suggest decision imprudent, e.g.: lower / delayed capex alternatives (e.g. gas) not fully explored, costly constraints not fully challenged, permits not in place ahead of proceeding, discount rates did not reflect project risk
- Imprudence can be traced to systemic decision governance issues, e.g.: lack of clear objective function and criteria/constraints of Hydro and regulatory body, rates not linked to allowable returns, iterative (vs. upfront) approach to investment decisions

2 Based on current outlook, project economics expected to worsen and remain sensitive to key uncertainties

- Capital execution will likely overrun and export price assumptions expected to worsen (outside of carbon constrained scenario)
- Equity ratios dip into single digits - similar to 1970-1995, but Province with 30%+ net debt/GDP vs. ~20% before

3 Despite these challenges, cancelling in flight projects to shift to alternatives is not a realistic option

- ~$5B already sunk on Bipole III and Keeyask with cancellation costs of ~$1B each, bringing effective total to ~$7B
- ~$3.2B cost to complete Bipole III West clearly more favourable vs. ~$4.5B rerouting costs of Bipole III East
  - Furthermore, decision to reroute Bipole III would strand Keeyask, making it uneconomic and likely trigger cancellation
- ~$4.7B cost to complete Keeyask yields an NPV $3-5B more favourable vs. switching to gas option, and avoids strategic risks

Exhibit 4: Were the original decisions the right ones?

Bipole III East was lowest-cost option to address longstanding, untenable reliability risk but was refused

- Reliability risk associated with Bipole I&II and Dorsey has been untenable for a long time: High concentration (e.g., 70% of energy), high incidence risk (e.g.,1/20 years), high societal impact (~$4-20B), major political implications
- Bipole III East lowest cost option but Provincial decision not to pursue based on environmental grounds
- Of remaining options, Bipole III West lowest cost vs. All gas and Import + gas

Original decision on Keeyask (with Tie-line) an imprudent decision

- New generation capacity required to meet domestic demand … but not until 2024+
- Keeyask project represents 2019 acceleration option to leverage US Tie-line import and export opportunity
- On paper, represents most favourable NPV option vs. delayed Keeyask (without Tie-line) or delayed gas
- Hydro generation deemed favourable vs. gas considering fuel price volatility and regulatory (e.g. CO_2) risk
- But assessment did not fully consider execution risks and sensitivities, e.g., project risk, industrial account risk, export price risk
- Additional downside financial risks of additional leverage (with Bipole III running concurrently) and associated discount rates to account for these risks did not appear to be fully factored into decisions
- Fuller assessment of lower capital and lower risk options would have been more prudent action at the time
  - Gas alternative
  - More aggressive challenging of costly constraints, e.g., regulatory requirement of Tie-line
  - Greater scrutiny of scope and design decisions

Imprudence can be traced to systemic decision governance issues

- Lack of clear objective function and criteria/constraints of Hydro, Government and Regulator, e.g., role of Hydro to drive economic growth vs. service domestic needs; role of regulator to maintain low rates vs. govern responsible stewardship of assets
- Ineffective rate-setting regime, e.g., rates not linked to allowable return, creating disconnect with system investment plan
- Iterative (vs. upfront) approach to investment plan decisions, e.g., ensuring full project scope considered holistically (Bipole III, Keeyask, US Tie-line) to appropriate capture compounded execution and financial risks

Exhibit 5: Mitigating risk of Bipole I&II, Dorsey a necessity

Represent unusually large contingencies

Bipole I&II carry majority of MH electricity
- ~70% of energy (MWh)
- ~50% of generation capacity[1] (MW)

Unable to meet winter demand without Bipole I&II
- 1500MW short of peak demand in 2017
- Assumes max. imports and running all thermal plants

Significant and real risk of catastrophic failure

Fire significant risk to Dorsey
- 1/29yr expected frequency[2]

Tornado at Dorsey unlikely but catastrophic
- 1/4000yr; Ellie[3] was scare
- Could take years to rebuild

Freezing rain and wind significant risk to Bipole I&II
- 1/20yr expected frequency

Ground ice buildup also risk to Bipole I&II
- Near-miss with shifted tower bases

~$4-20B societal impact of prolonged outage

Outage likely to last weeks to months
- 5-8 weeks for Bipole I&II
- Weeks to year(s) for Dorsey

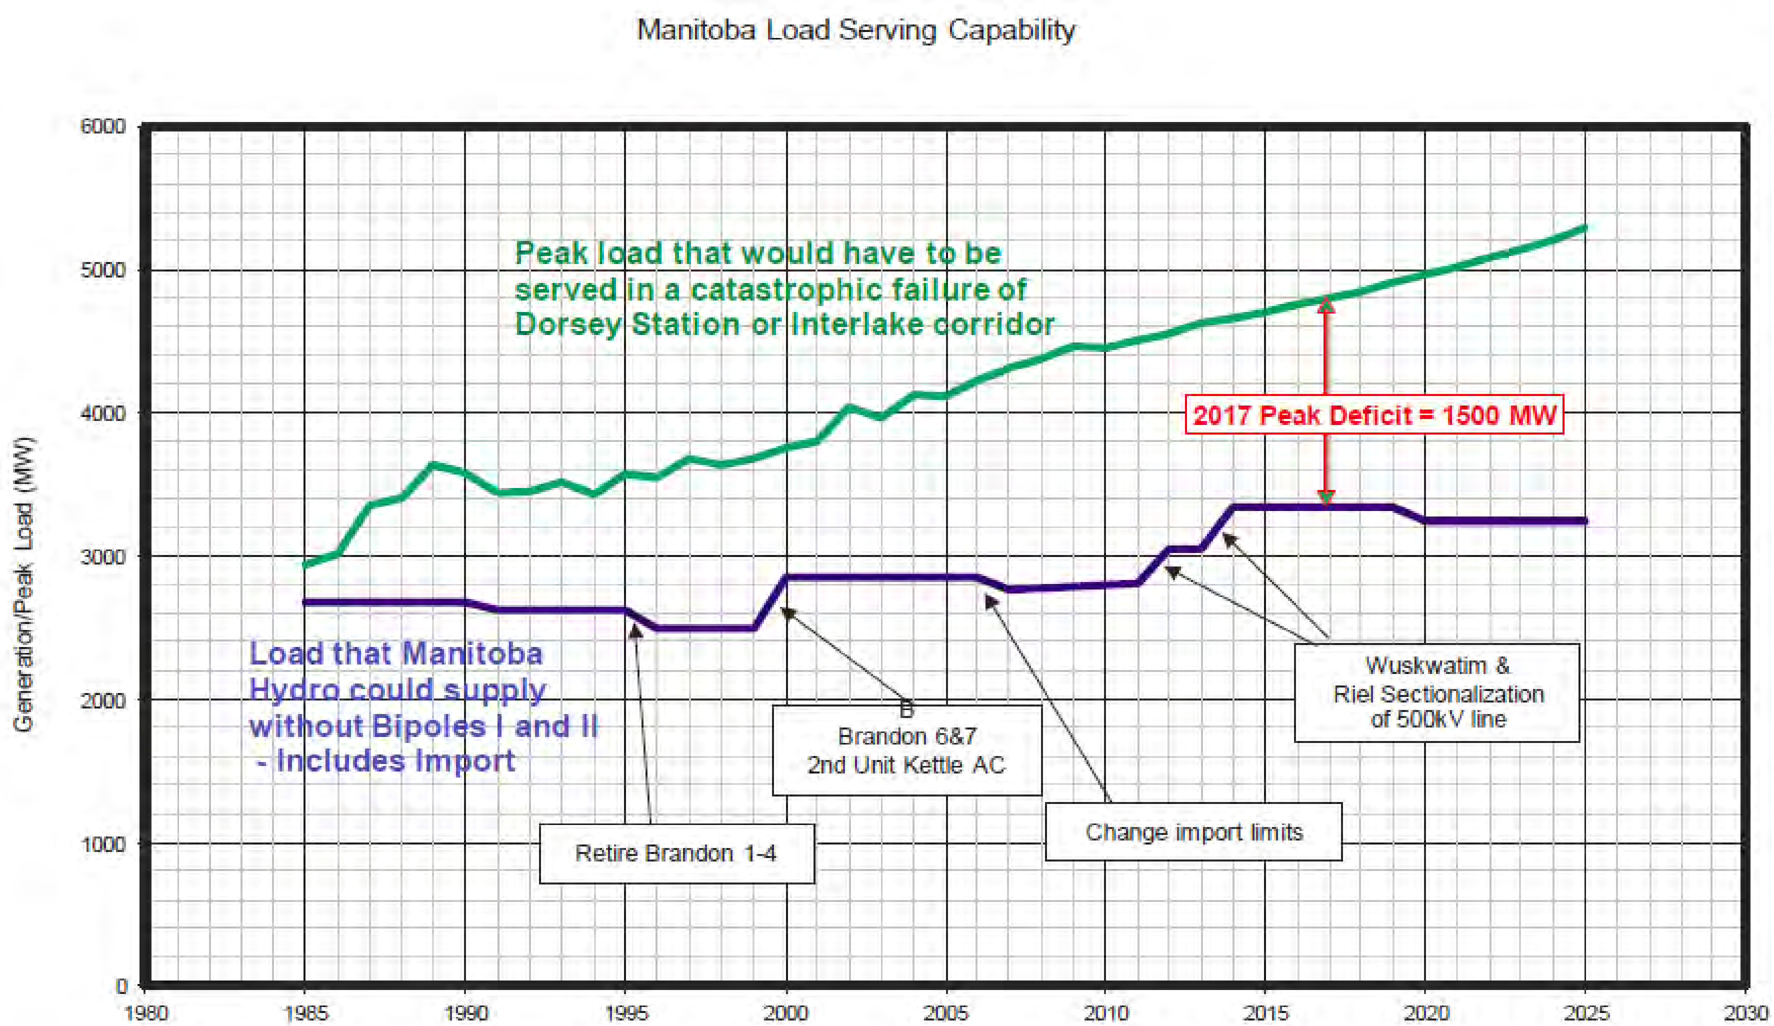
Rolling blackouts and/or demand curtailment
- Must force demand down to supply limit

~$4-20B cost depending of type and time of outage
- ~$10/kWh that fail to supply
- ~$4B for Jan. line outage
- ~$20B if full year

Popular backlash against MH and government likely
- Failure to honor Hydro Act

1. Total (100%) includes both generation and import line capacity. 2. After hardening of relay building in 2011 risk may be lower than stated in the reports.
3. Strongest tornado in Canadian history, 25km away.
Source: Teshmont (2001, 2006, 2012)

Exhibit 6: Peak load growth making loss of Dorsey or Bipole I & II consequences more severe (1.5 GW peak shortfall in '17)



Source: Reliability Alternatives for Mitigating the Risks of a Dorsey or Interlake Corridor Outage (2011)

Exhibit 7: Probabilistic studies show risk to Dorsey and Bipole I & II, and there have been several near misses

Threat	Dorsey[1]	Bipole I & II
Tornado, downburst	**1/4000yr** (summer) Down ***month to year(s)*** • 3km away (Sep. '96) • 25km away[2] (Jun. '07)	**1/17yr** (summer) Down ***days to weeks*** • 19 towers destroyed (Sep. '96)
Fire	**1/29yr** Down ***week to months*** • Exploding transformer	**N/A**
Wide-front wind	**1/200yr**	**1/90yr** Down ***week to months***
Freezing rain & wind	**1/50yr**	**1/20yr** Down ***week to months***
Ground ice buildup	**N/A**	Unknown; **likely significant** • Tower bases shifted from the ground
Sabotage	**Unknown**	**Unknown**

1. After hardening of relay building in 2011 several of the risks to Dorsey are likely lower than stated in the reports. 2. Elie; strongest tornado in Canadian history
Source: Teshmont (2001, 2006, 2012)

Exhibit 8: Societal impact of loss of Bipole I & II or Dorsey for month of January ~C$4B, and ~C$20B for full year

Low societal impact ↔ High societal impact

Short-term outage	Dorsey / Bipole I & II	Severe weather outage
Temporary (minutes–hours) inability to serve load • Black/brown-out	**Prolonged (week–year) inability to serve load** • Rolling blackouts • Shed industrial load • Prioritize residential heating	**Prolonged (day–week) inability to supply power** • Black-out until repair
MISO Value of Lost Load (VoLL) estimates: • Residential[1]: US$2/kWh • Small C/I: US$42/kWh • Large C/I: US$29/kWh	**MH VoLL estimate:** • C$10/kWh • Very unusual situation with uncertain long-term effects	**1998 Canada ice storm** • C$9/kWh **2012 Superstorm Sandy** • ~US$20B; 8.5M lost power

Bipole I & II transmission lines (for January)
- Un-served January demand * C$10/kWh = **~C$4B/mo**

Dorsey converter station (for a year)
- Un-served annual demand * C$10/kWh = **~C$20B/yr**

1. Likely higher for customers reliant on electric heating, and may underestimate modern reliance on electronics

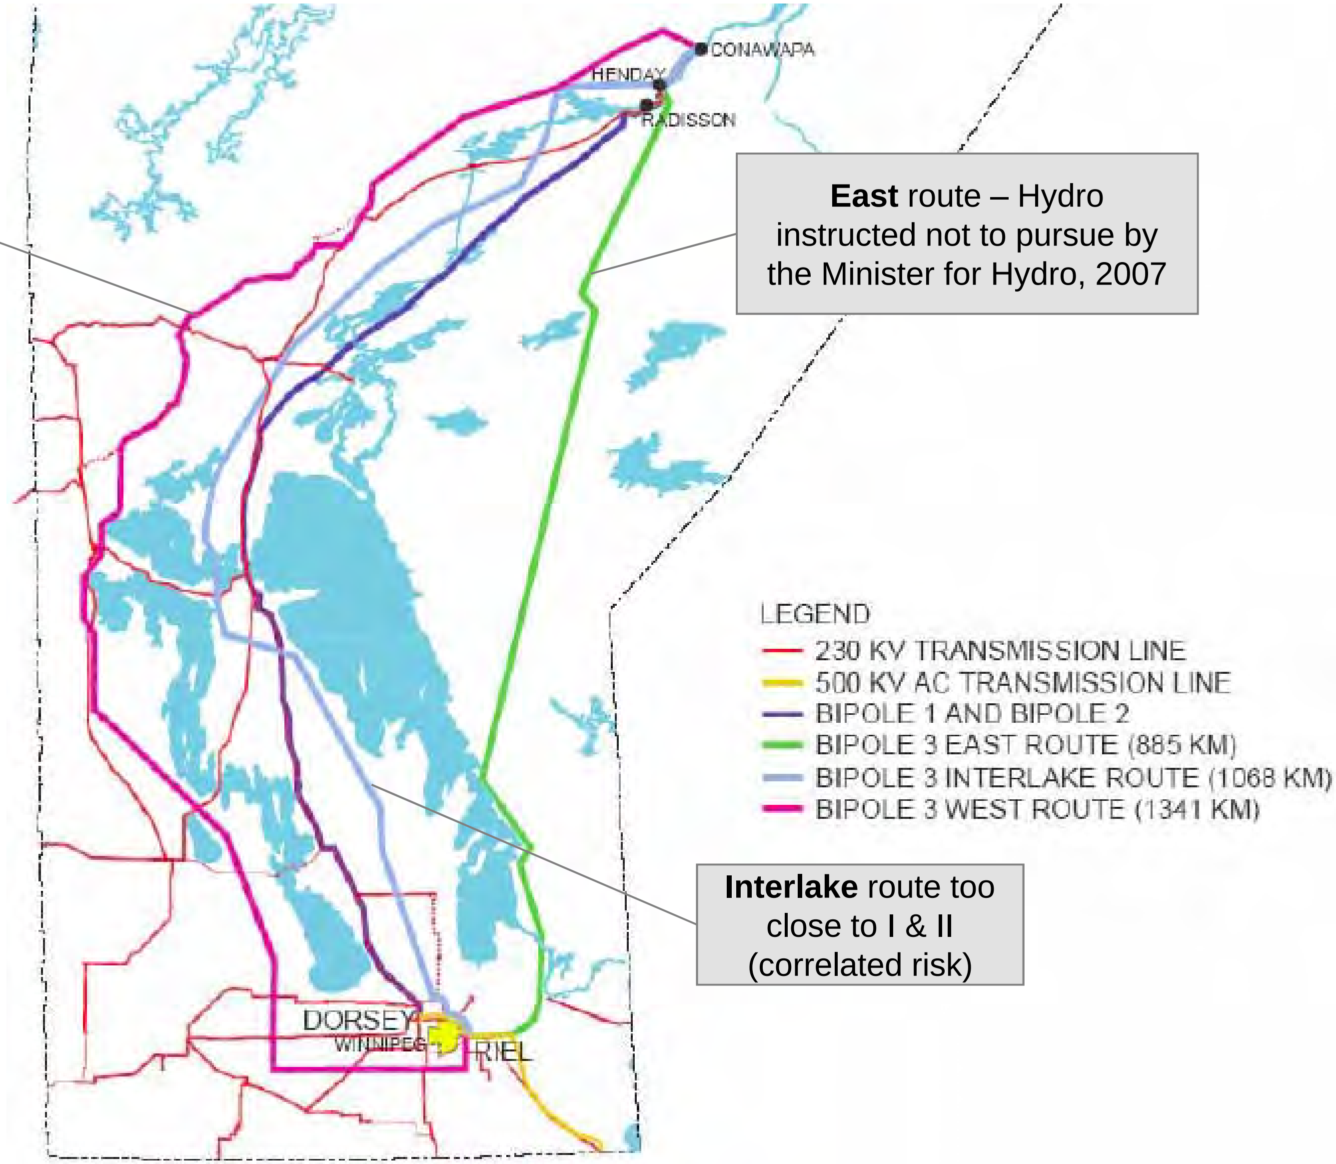
Source: "Estimating the Value of Lost Load", London Economics (2013); "Manitoba Customer Interruption Cost Evaluation", R. Billington, PowerComp Associates (2001); "Economic Benefits of Increasing Electric Grid Resilience to Weather Outages", Executive Office of the President (2013)

Exhibit 9: Bipole III West route chosen to minimize risk correlation with Bipole I & II

West route longer but satisfies requirements

East route – Hydro instructed not to pursue by the Minister for Hydro, 2007

Interlake route too close to I & II (correlated risk)



Source: Teshmont 2006

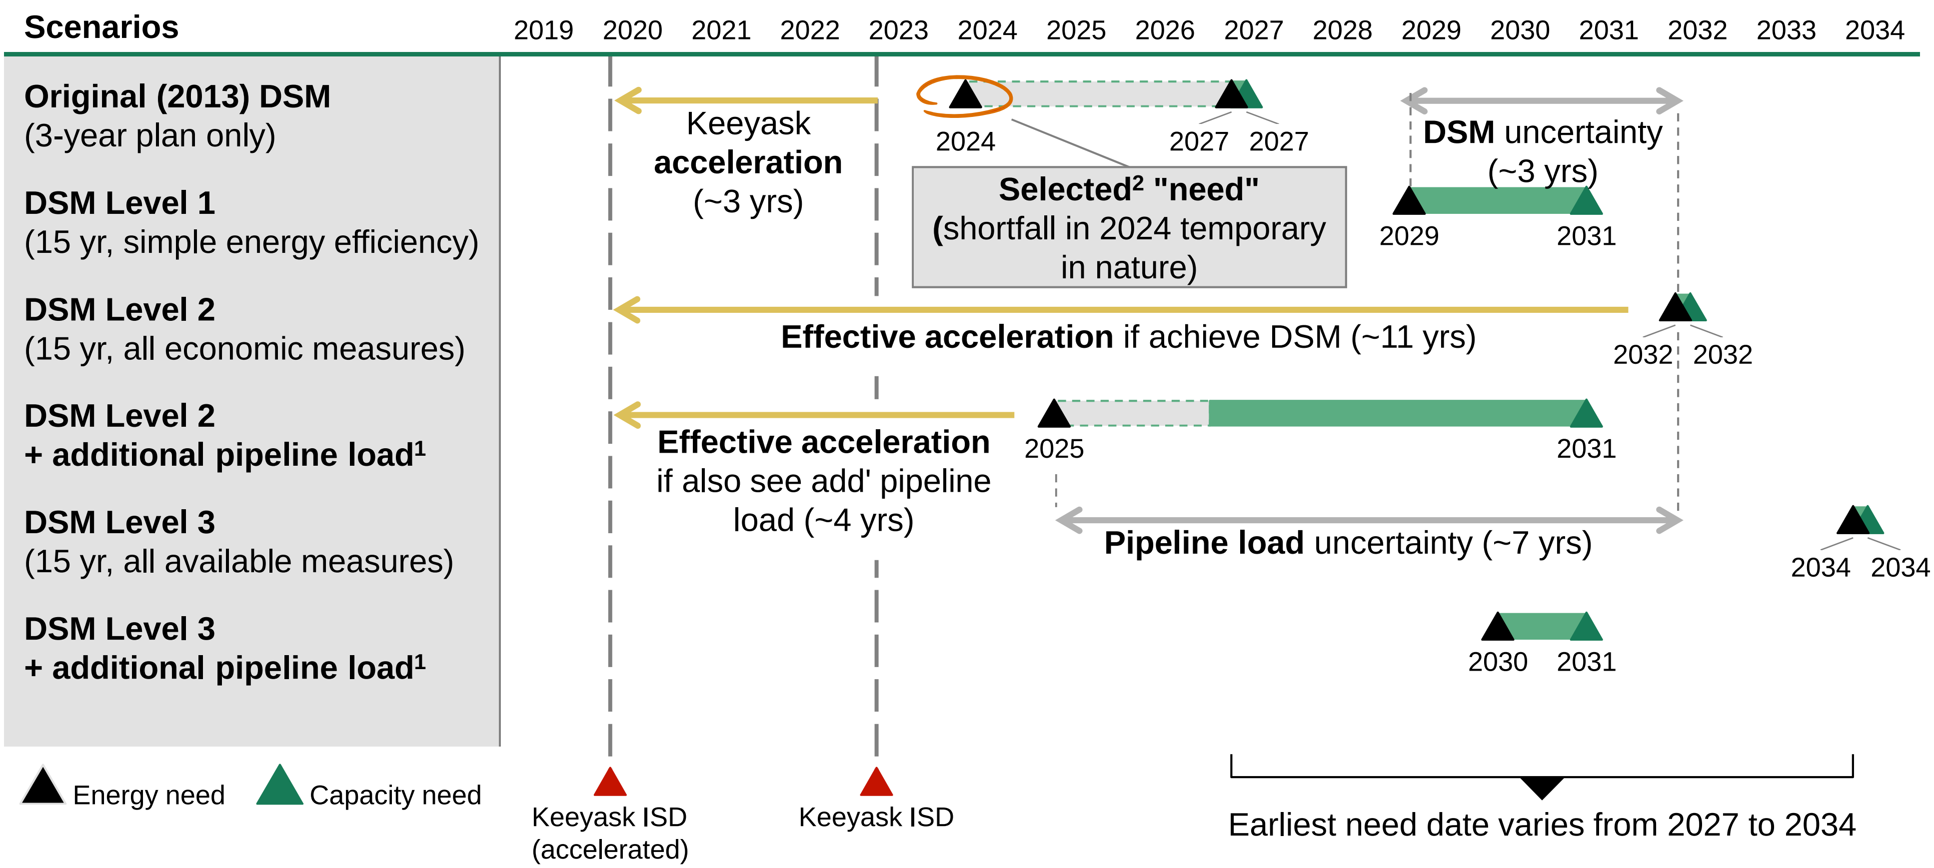
Exhibit 10: Bipole III East the most favourable option

But directed not to pursue by previous government, hence Bipole III West pursued

	Lowest cost, not selected **Bipole III East**	*Selected option* **Bipole III West**	**All-gas**	**Import + gas**
Description	**Alternative access to northern hydro** • 2000MW line • Could stage (line first, conv. stations later[1])	**Alternative access to northern hydro** • 2,300MW line • Cannot stage line and converter stations	**Backup generation** • 2000MW gas in the South	**Import line + backup generation** • 1500MW US line • 500MW gas
Cost estimate used in 2011 EIS[4]	Not formally assessed but estimated to be $900m less expensive • Staged converter station build • 700-900km shorter	**~$3.3B** (capital cost in-service dollars) **~$10M/y** annual cost	**~0.7B** more than BPIII on PV[2] basis **~$3B** gas turbine **~$181M/y** pipeline reservation fee + variable costs	**~$4.5B** (capital cost in-service dollars) Annual costs subject to contract terms and variable costs
Additional benefits	**$28M/yr from reduced losses[3]** **Additional capacity for new hydro**	**$26M/yr from reduced losses[3]** **Additional capacity for new hydro**	**More dependable energy**	**Larger import/ export potential** **More dependable energy**
Risks	**Route through Boreal forest**	**No specific risk**	**Environmental risk, pipeline reservation fee**	**Environmental risk, future price of securing capacity**
Verdict	**In 2007 the province directed MH to study Western routes**	**Lowest cost of available options**	**Higher cost, CO_2-emitting**	**Higher cost, CO_2-emitting, difficult to secure US partner**

1. Line primary concern, given low probability of Dorsey destruction. 2. Present Value. 3. Current Bipole I&II transmission losses 8.6%; Bipole III West 6.4% to 7.0%; Bipole III East 6.0% to 6.4%.
4. Environmental Impact Statement (2011)
Source: Manitoba Hydro, BCG analysis

Exhibit 11: Timing of domestic requirements



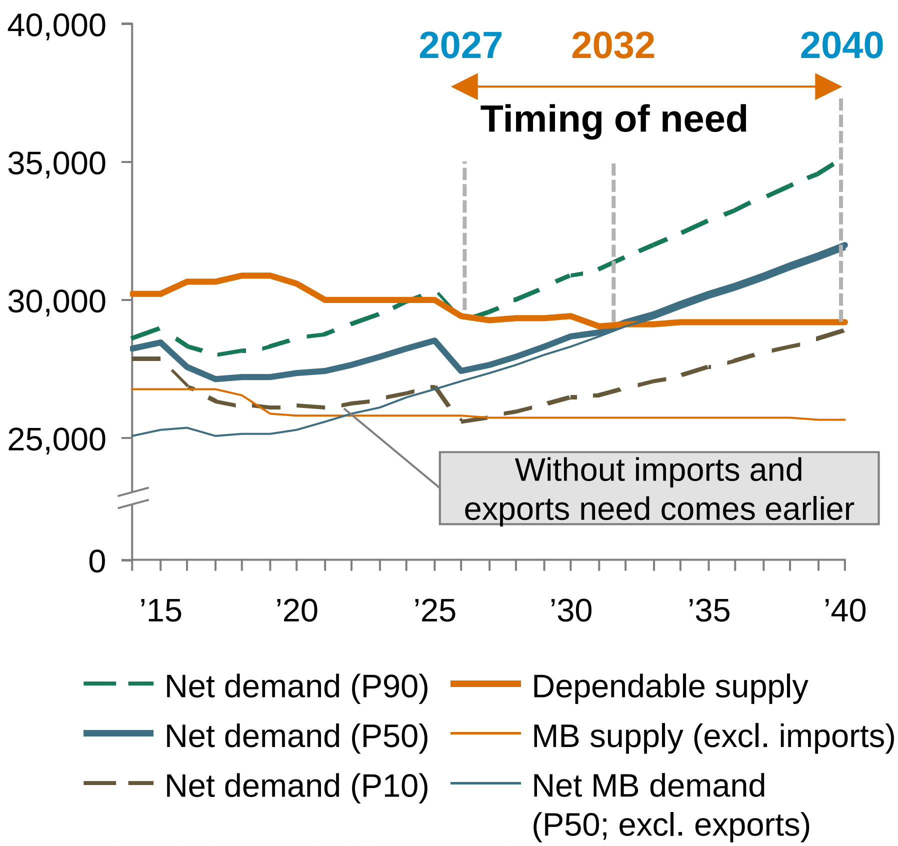
Realistic DSM pushed need date out, but expected additional pipeline load pulled it back to ~2027

1. 1700MWh additional load planned by pipeline customers. 2. Put forward by MH, and accepted by NFAT panel (partly because they expected additional pipeline load to materialize).
Source: NFAT Final Report

Exhibit 12: New generation capacity required, although not until 2027 or beyond

NFAT: Supply vs. net demand[1]

Dependable energy supply vs. net demand (GWh)



1. Gross demand minus DSM, including exports unless noted
Source: Manitoba Hydro (NFAT)

Timing subject to forecast uncertainty

Gross demand forecasted to grow by 1.5% p.a.
- ***Residential segment:*** Population growth and increased penetration of electric heating
- ***Mass market segment:*** GDP growth (2%) and population key drivers
- ***Top customers segment :*** 17 companies, "Potential Large Industrial Loads" longer term

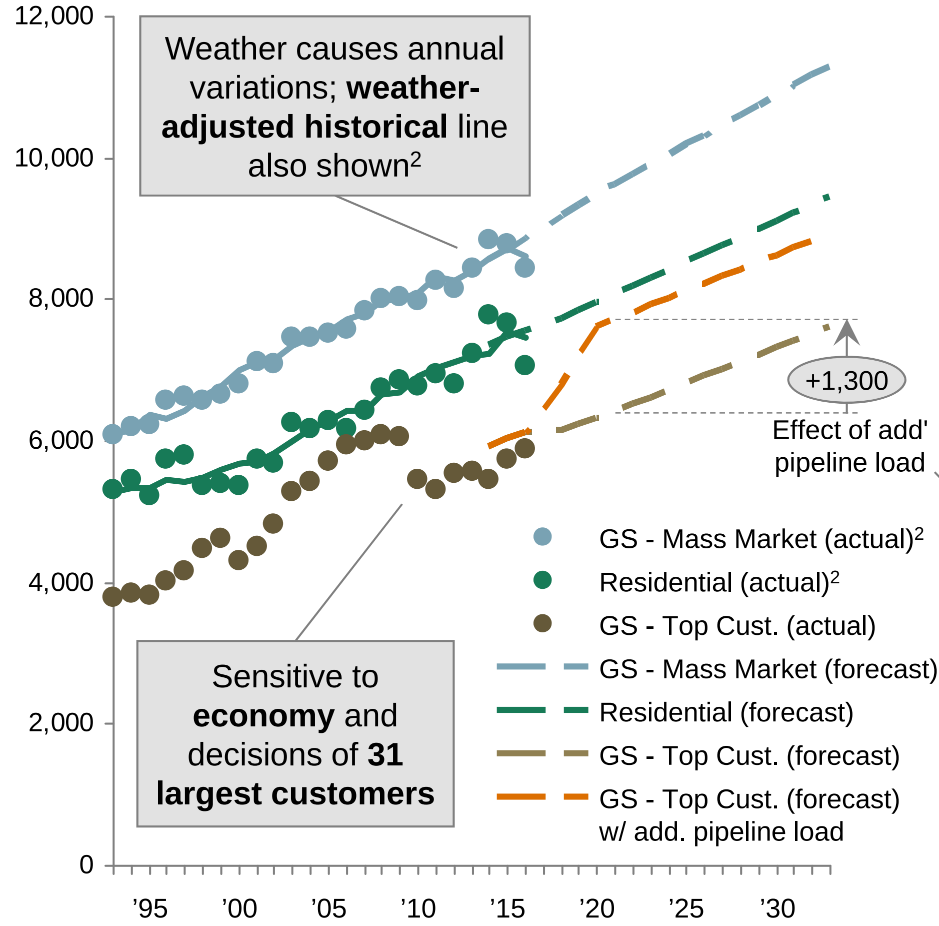
Demand Side Mgmt. (DSM) expected to offset 66% of demand growth over 15 years
- ***Conservation rates:*** MH proposed higher rates for electricity beyond threshold
- ***Fuel switching:*** Switch to gas heating
- ***Load displacement:*** Industrial self-generation

Uncertainty for both gross demand & DSM
- Decisions of larger industrial customers (e.g., pipeline load)
- DSM adoption may be lower than in other markets due to low retail rates

Exhibit 13: Gross demand forecast sensitive to Top Customers

Forecast methodology sound, but inherent risk in lumpy Industrial demand

Customer segment gross demand[1] (GWh)



Demand forecast by customer segment

Methodology to forecast demand by segment

- ***General Service – Mass market:*** GDP and residential customer number drive demand
- ***Residential segment:*** Population, electric heating penetration, etc. drive demand
- ***General Service – Top Customers:*** Individual forecasts for top 31 drive near-term demand; annual PLIL[3] increment beyond that

Historically, demand forecast accurate for General Service and Residential

Top Customers largest source of uncertainty

- Sensitive to largest customers and economic cycles
- E.g., expected 1700GWh add' pipeline load (+1300GWh over PLIL[3]) but only ~500GWh now expected to materialize

1. Gross MB demand shown; net demand is gross demand minus DSM, plus net exports. 2. Weather-adjusted line also shown (N/A to Top Cust.). 3. Potential Large Industrial Loads
Source: Manitoba Hydro

Exhibit 14: NPV & upside favoured Keeyask by 2019 + Tie-line

But at substantially higher capital risk vs. delayed gas option

Selected option

Criteria	Gas generation 2022+	Keeyask 2025/26	Keeyask '19 + Tie-line
Resource type	***Fossil*** *(CO_2 emitting; fully dispatchable)*	***Renewable*** *("new hydro"; dispatchable subject to water)*	***Renewable*** *("new hydro"; dispatchable subject to water)*
Cost structure	***Variable cost intensive*** *CAPEX (PV[1]): ~$2.8B* *Variable cost: ~$40-62/MWh* *LCOE[3]: ~75-265 $/MWh[4]*	***Capital intensive*** *CAPEX (PV[1]): ~$4.4B* *Variable cost[2]: ~$3-4/MWh* *LCOE[3]: ~68 $/MWh*	***Capital intensive*** *CAPEX (PV[1]): ~$6.2B* *Variable cost[2]: ~$3-4/MWh* *LCOE[3]:~68 $/MWh[5]*
NPV (NFAT)	***Reference case***	***–$38M*** *benefits to MH and* ***$591M*** *payments to province compared to gas reference*	***+$386M*** *benefits to MH and* ***$1148M*** *payments to province compared to gas reference*
Upside and risk	*Higher or lower* ***gas and CO_2 prices*** *than forecast* *Federal or provincial* ***restrictions on CO_2***	*Increased export prices from* ***US Clean Power Plan****, etc.* ***Cost*** *and* ***schedule overrun***	*Increased export prices from* ***US Clean Power Plan****, etc.* ***Cost*** *and* ***schedule overrun****, and tie-line* ***permitting***

1. Present Value of capital expenditure for scenario (including late-time gas generation) 2. Only water rental included here 3. Levelized Cost of Electricity. 4. Varies by utilization. 5. Keeyask only.
Source: NFAT, BCG analysis

Exhibit 15: Tie-line a key source of value for Keeyask project

Greatly improves economics of Keeyask given potential for export to subsidize low domestic rates

Minnesota Power needed rapid path to reduce CO^2

The problem

- MP legally mandated to achieve 26.5% RPS by 2025
- MP had set its own target to produce 1/3rd of current 1900 MW from renewables
- CPP may require MP to reduce 30% CO^2 from coal by ~2030
- Can only import <u>new source of renewable power</u>

MP were looking for a near-term solution

MP had several options to solve CO^2 challenge

Several options to solve

- Build out wind
- Wait for utility scale PV to drop in price (as per trend)
- Start build out of gas
- Lock in new source of hydro power to import (Keeyask provided the option)

Keeyask one of several viable options considered

Building Keeyask and tie line had benefits for MH

With the tie line, MH gets

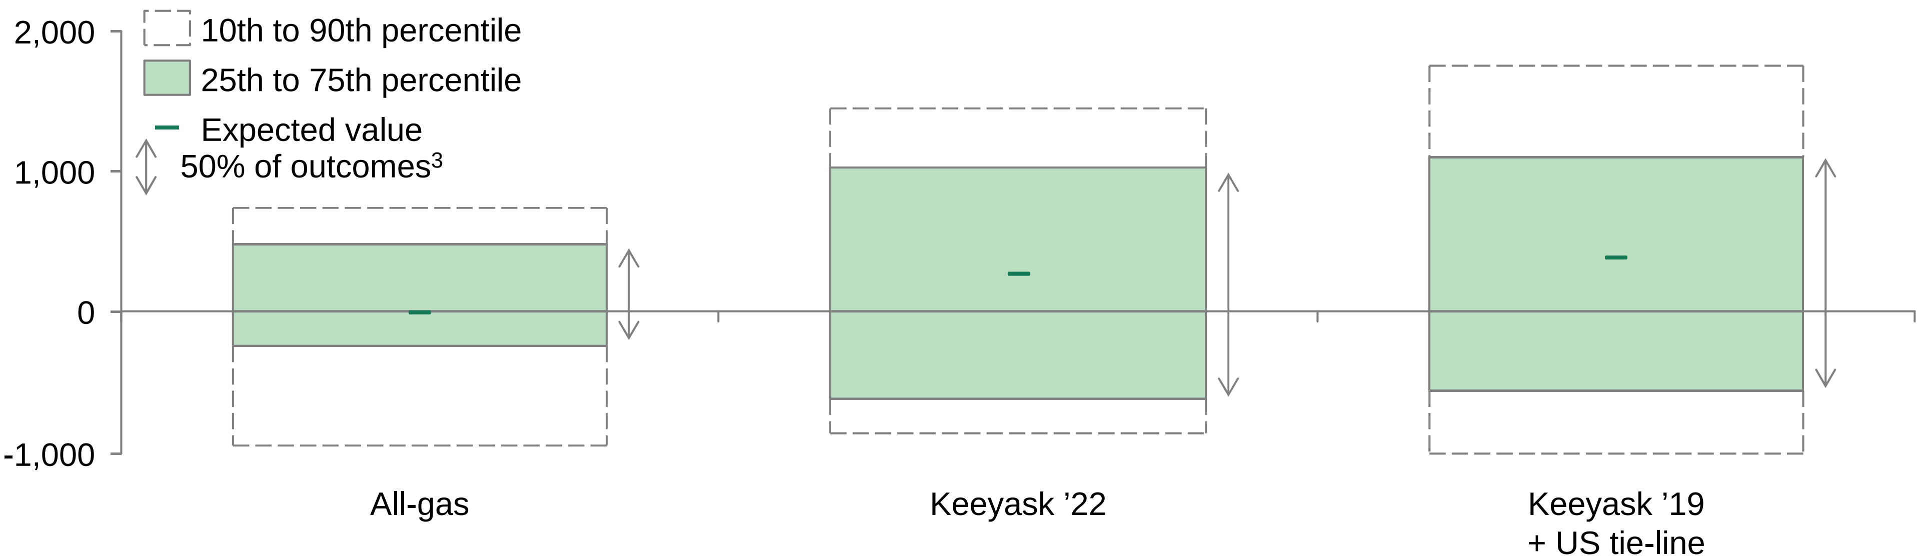
- ~3 TWh new cost-effective dependable energy
- Import capacity of ~700MW dependable capacity to offset hydro risk
- 885MW increase in export capacity used to offset construction cost of Keeyask

MH built early to capture benefits in a closing window

Exhibit 16: Gas carried less uncertainty, but Keeyask with tie-line had higher expected incremental NPV[1]

Gas generation 2022+	Keeyask 2025/26	Keeyask '19 + Tie-line
Smaller and staggered capital costs, with future fuel expense	**Large capital investment**	**Large capital investment and early additional export rev.**
Key sensitivities (discount rate, energy prices, capital costs) can vary NPV by -$1B to +$0.7B	**Expected incremental NPV ~$0.3B, but more sensitive (ranges from -$0.8B to + $1.4B)**	**Highest expected incremental NPV (~$0.4B), but also most sensitive (largest up/downside)**

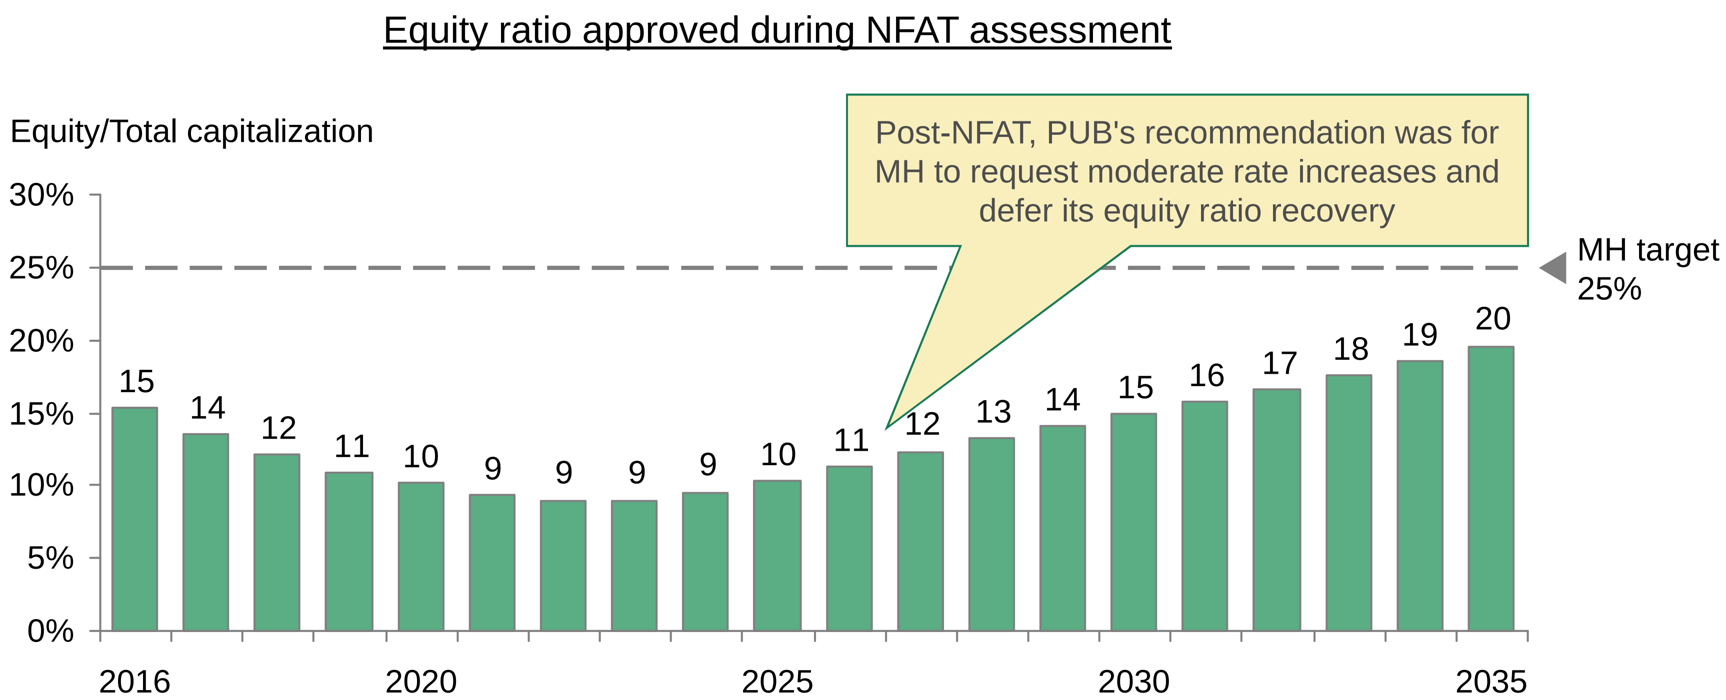
Incremental NPV[1] over all-gas reference case[2] ($M)



1. Having sunk $1.2B. NPV benefit to Manitoba Hydro only (excluding water rental and capital tax and guarantee fee payments) 2. All-gas reference case with reference values for discount rate, energy prices, and capital costs. 3. Considering uncertainty in discount rate, capital costs, and energy prices. Note: Manitoba Hydro did not update this analysis to reflect final DSM level 2 demand forecast
Source: NFAT final report

Exhibit 17: Implied equity ratios of NFAT submissions

NFAT and PUB supported equity ratio falling to 9%

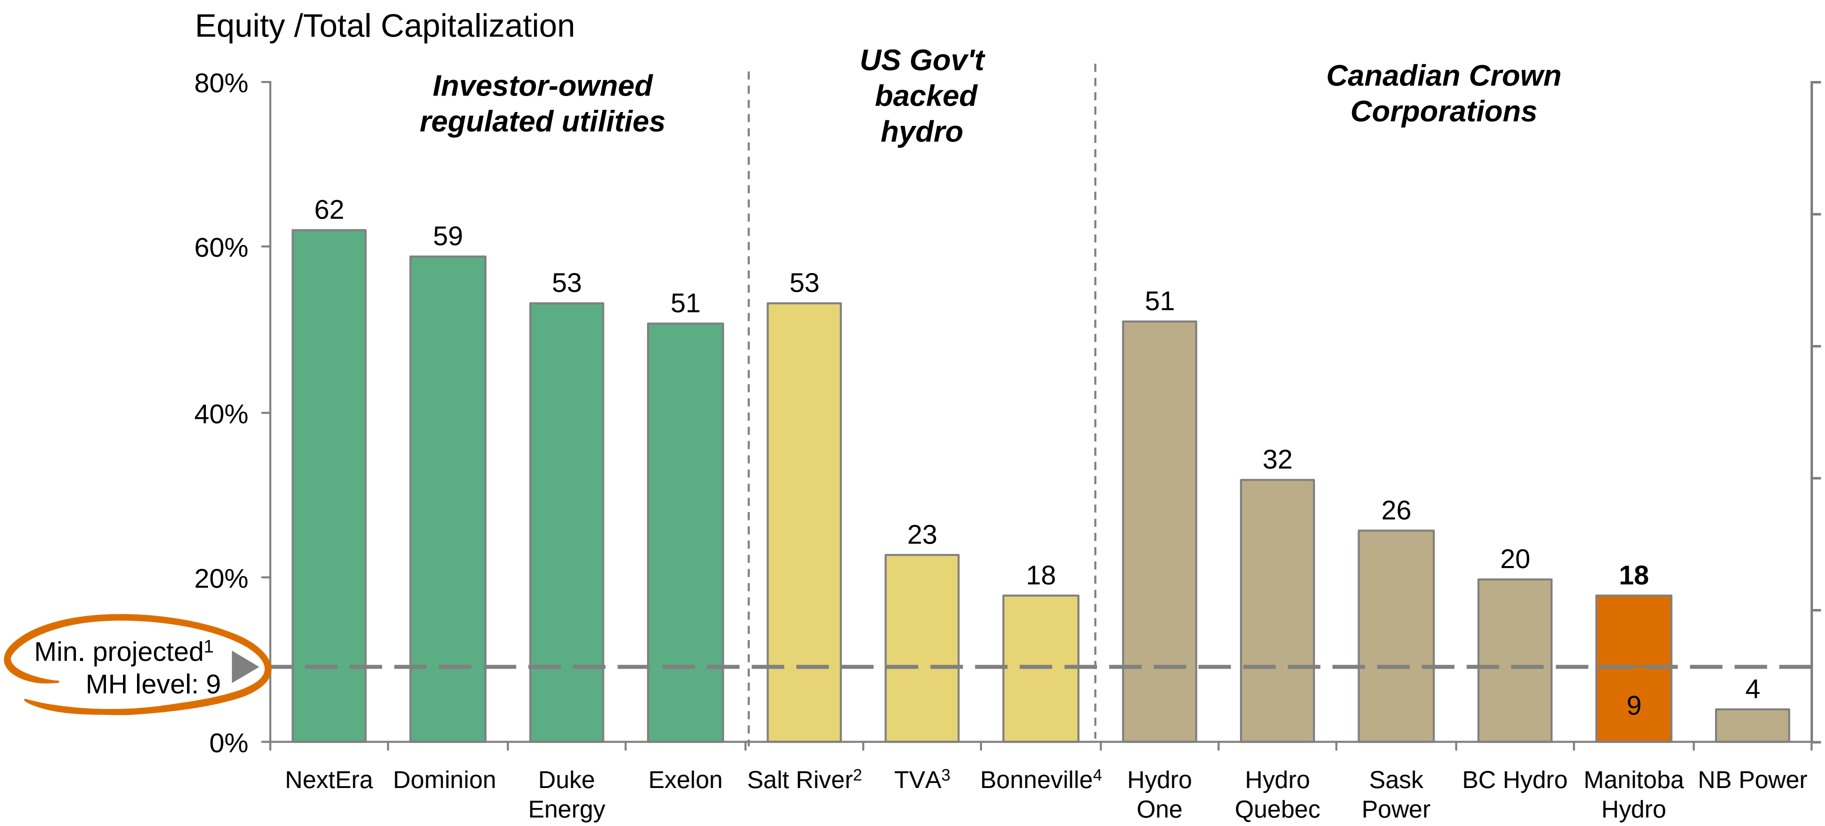


Single digit equity ratios were not highlighted as a significant risk when projects approved

Source: IFF '15; NFAT Projected Financial Statements for Plan K19/Gas/750MW – DSM Level 2

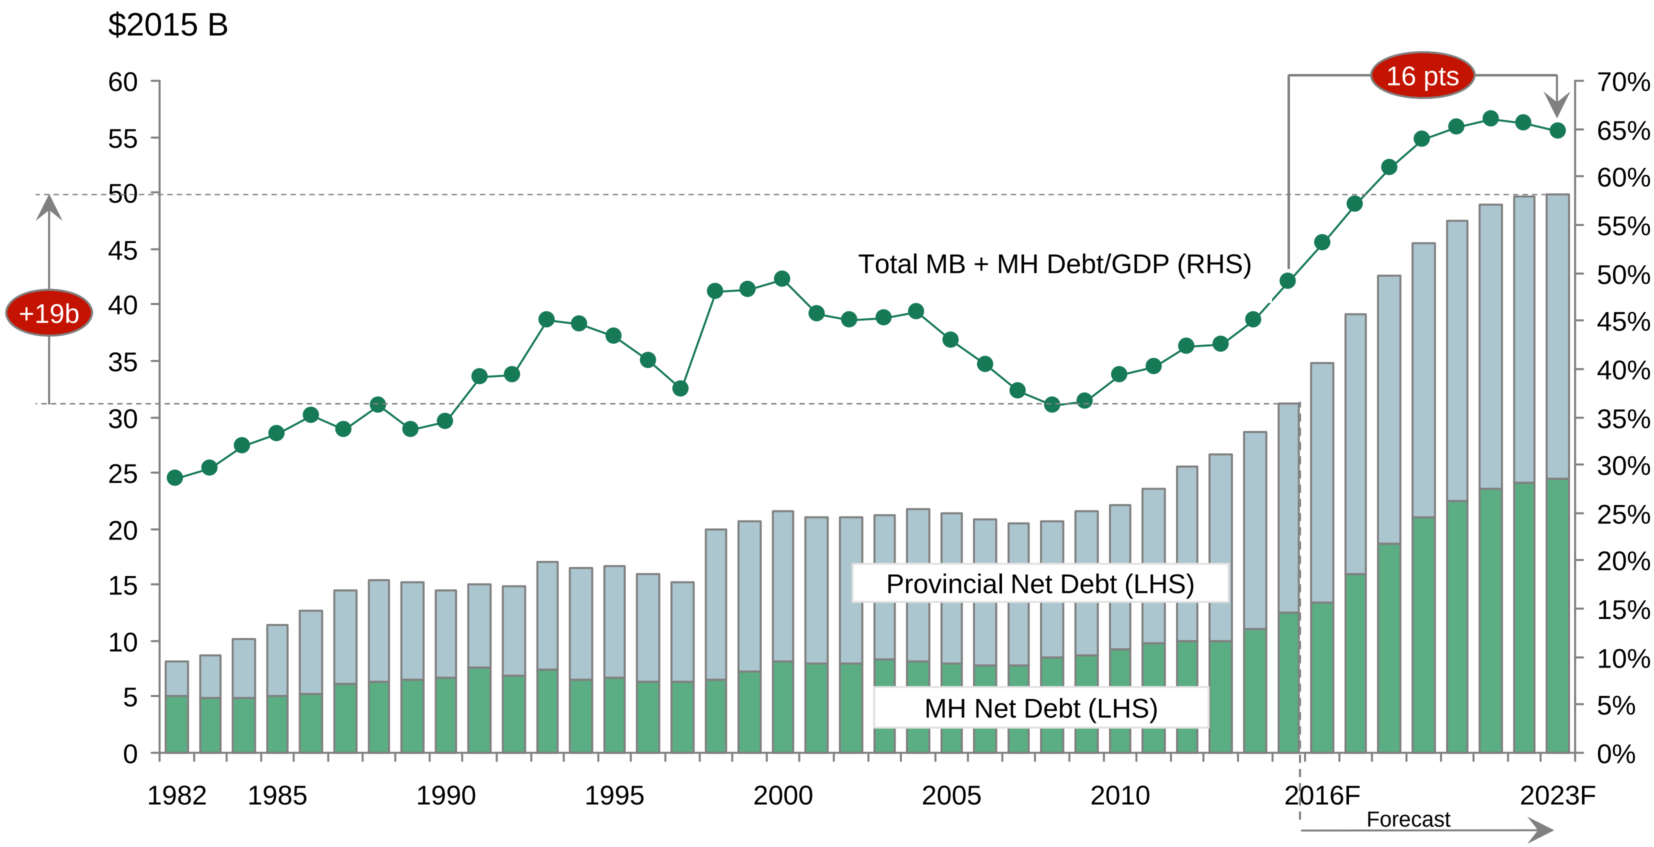
Exhibit 18: Equity ratios well-below most peers

Capital structure and credit rating for US and Canadian gov't and investor-owned regulated utilities



1. 2022 Expected Equity Ratio on NFAT Base Case 2. Salt River Project an entity of the State of Arizona 3. Federally owned corporation 4. US Federal administration within Dept. of Energy
Source: 2015 Audited Financial statements, SNL

Exhibit 19: Hydro debt included, total debt-to-GDP ratio forecast will increase to 65%



2015 Debt/GDP
(including utility[4])

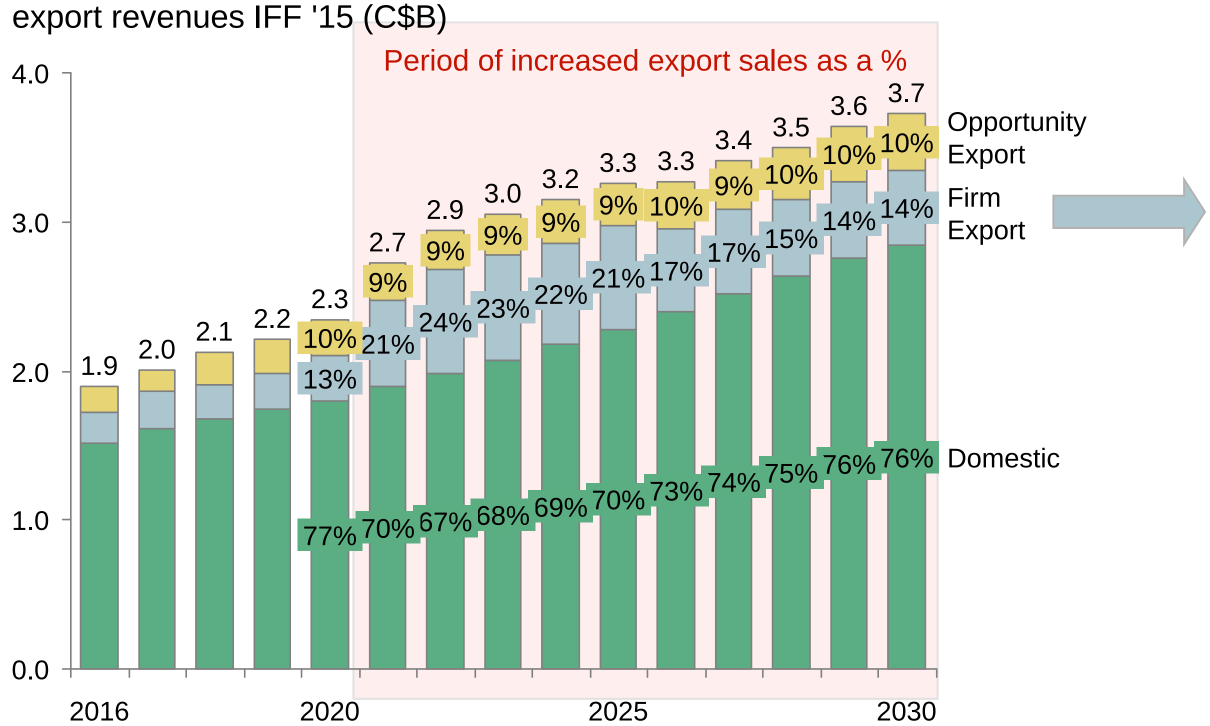
Limited capacity for the Province to provide debt backstop

Source: Canadian Department of Finance, Manitoba Hydro Debt Management Strategy Report, RBC, 2015 Utility Annual Reports
1. Total Debt calculated as Provincial Net Debt + Manitoba Hydro Net Debt in base case. 2. Debt to GDP ratio from RBC report; excludes Manitoba Hydro debt 3. Provincial debt forecasts modeled based on Provincial target to close budget gap within 8 years 4. Provincial net debt with utility crown corporation debt included 5. Ontario Provincial debt plus OPG debt (including asset removal and nuclear waste management liabilities)

Exhibit 20: Firm export volumes and prices benefit economics

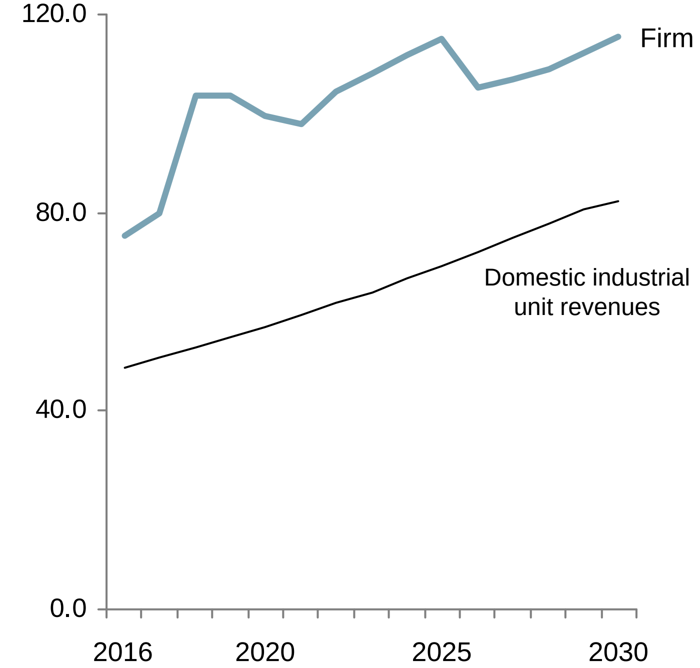
Revenue mix expectations: Firm export expected to grow to 20%+

Forecasted domestic demand and export revenues IFF '15 (C$B)



Price expectations: Firm export at 15% premium

Unit revenues IFF'15 ($C/MWh)



Source: Manitoba Hydro, BCG analysis

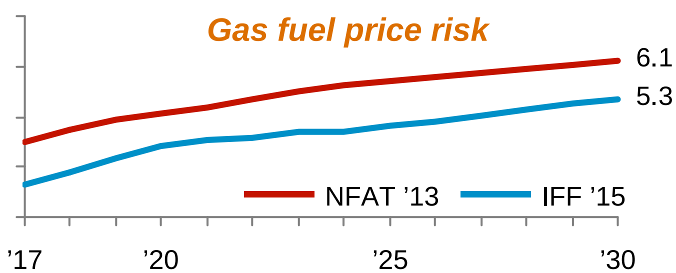
Exhibit 21: Gas & CO_2 price risk vs. Hydro & Export price risk

Manitoba's resources and the current regulatory model better fits with the hydro based risk profile

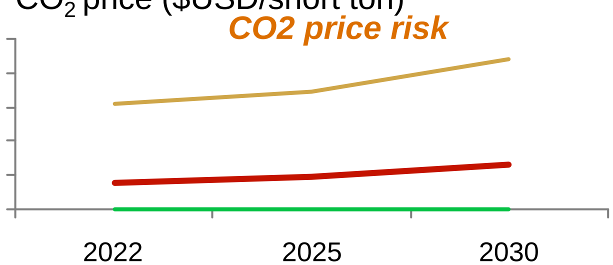
Selected option

Criteria	Gas generation	Hydro generation & US Tie-line
Risks	*Domestic price & fuel price volatility* *Environmental regulation risk incl. CO_2* *Fuel import dependency*	*Risk related to water levels* *Domestic & export price levels* *Execution risk (e.g. project complexity)*
Increase of Gas & CO2 prices with upward impact on Export prices and hence benefitting MH's hydro assets		

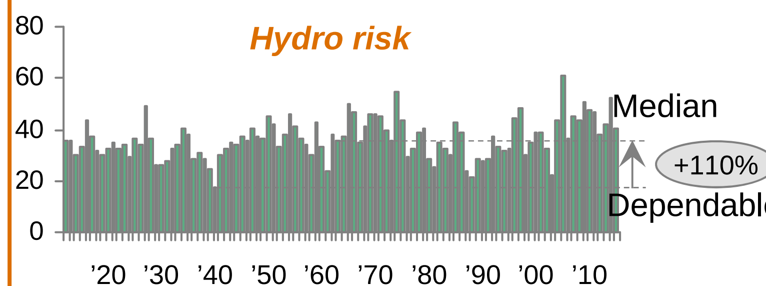
Price ($2015 USD/MWh)



CO_2 price ($USD/short ton)



Energy from water flow (TWh)



MISO Minnesota price forecasts ($/MWh)

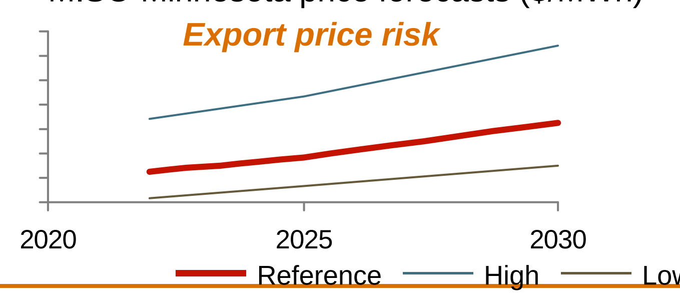


Exhibit 22: Manitoba Hydro's regulatory framework oriented towards maintaining consistent, low price increases

Hydro Act	**Outlines Manitoba Hydro's core purpose: to provide sufficient power for Provincial needs and engage in the activities required to provide power economically and efficiently** • Regulatory framework allows for exports of power **Directs that prices be set such that MH can recover operating and interest costs and build sufficient reserves to fund replacement of assets and new investment in property or plant** • Act also outlines MH's ability to borrow under Provincial guarantee
+	
PUB	**PUB mandate exclusively to review the price of power; no supervisory authority granted** **Track record of PUB to prioritize low, stable increases over time rather than implement lumpier price increases timed with capital expenditures**
+	
Provincial Cabinet	**Province reviews capital plans, export contracts and interconnect agreements** • Province may direct PUB to review other elements of MH's operations on its behalf
+	
Other legislation	**MH also subject to other legislation that influences PUB and public attitude towards price:** • Affordable Utility Rate Accountability Act requires Manitoba to have lowest combined price of gas, electricity and auto insurance among provinces • Clean energy legislation governing development of renewables prioritizes low rates

Exhibit 23: Manitoba regulatory construct different from traditional utility cost-of service model on several dimensions

	Manitoba PUB "Modified" Cost of Service	Traditional Cost of Service
Rate framework	**Price of power set based on PUB judgment** **PUB considerations:** • Operating expenses • Retained earnings reserves • Proposed capital plans • Smooth trajectory of rate increases	**Revenue requirement = Operating Expenses + (Gross value of the utility's tangible and intangible property – Accrued depreciation) * Allowed Return on Rate Base**
Objective function	• **Provide sufficient power for Provincial needs and engage in the activities required to provide power economically and efficiently**	• **Maximize return within regulatory bounds**
Investor	• **Government**	• **Institutions and individuals**
Return on equity	• **Outcome of rate setting process** • **Varies with revenue increases**	• **Primary lever of rate setting process** • **Set at level to attract private capital**
Capital Plan	**PUB informed of plan but no formal approval**	**Regulatory approval of CapEx required before addition to rate base**
Supervisory Authority	**PUB lacks supervisory authority**	**Regulatory supervisory authority granted**
Allowance/ disallowance	**No disallowance authority from PUB**	**Regulatory authority to disallow expenditures from rate base**

Exhibit 24: Decision making more iterative than consolidated

Reliability	*Energy and Capacity*		*Rate application*
Clean Energy Commission '13	**PUB in the NFAT '13-14**		**PUB rate process '15**
Bipole III West Route for 2018 ISD	**Keeyask 695MW Hydro for 2019 ISD**	**750MW US Tie Line for 2020 ISD**	**Increase Manitoba rates by 3.95%**
Bipole III East Route	All Gas (various types and ISDs)	250MW US Tie Line for 2020 ISD	Various rate increase scenarios presented
Gas	Keeyask 695MW Hydro for later ISD (2022)	DSM included in all options	
Import and Gas	Conawapa 1485MW later than 2026 ISD	Other resources (e.g. wind, solar)	
Import only	Increase of import and change planning guidelines[1]	Push out ISD of US tie-line for later	Efficiency measures

Current option

Alternatives considered

Alternatives not considered

1.Import can account for up 10% of Manitoba load plus export, overall capped at 50% of the off-peak load
Source: BCG analysis

Exhibit 25: Is there further downside risk?

Outlook under current assumptions already highly sensitive to performance across 6 key factors:

1) **Water flows / Hydro risk: No change to existing range of uncertainty for near term-impact**
   - High variability in range of possibilities

2) **Capital execution costs**: **Both projects likely to exceed P90**
   - Bipole III expected to run over by $0.3B with 12 month delay and Keeyask expected to run-over by $0.7B with 21 month delay, including interest
   - For Bipole III, transmission line construction productivity in winter and tower steel availability the main drivers

3) **Export prices: Expected to worsen (outside of longer term carbon constrained scenario)**
   - Most recent forecasts represent a ~13-17% decrease in long-term export prices vs. IFF '15
   - Firm energy premium reducing up to 10%

4) **Interest rates: Favorable movement since NFAT in long term rate**
   - Assumptions of long term rates fall from 6.3% to 4.4%, reducing debt service levels and discount rate

5) **Domestic rates: Potentially lower than forecast initially**
   - PUB granted 3.36% vs 3.95% as requested (partially due to lower interest rate and debt servicing cost)

6) **Net domestic demand: No change to expected case**

Equity ratios expected to dip to single digits, creating a potentially precarious position for the province

- Falls to <12% in expected scenario
- Under extreme sensitivities (severe capex overrun, sustained drought), feasible for equity to go below 5%
- While single-digit equity ratios observed 1970-1995, Province with 30%+ net debt/GDP vs. ~20% before

Exhibit 26: Project economics expected to worsen

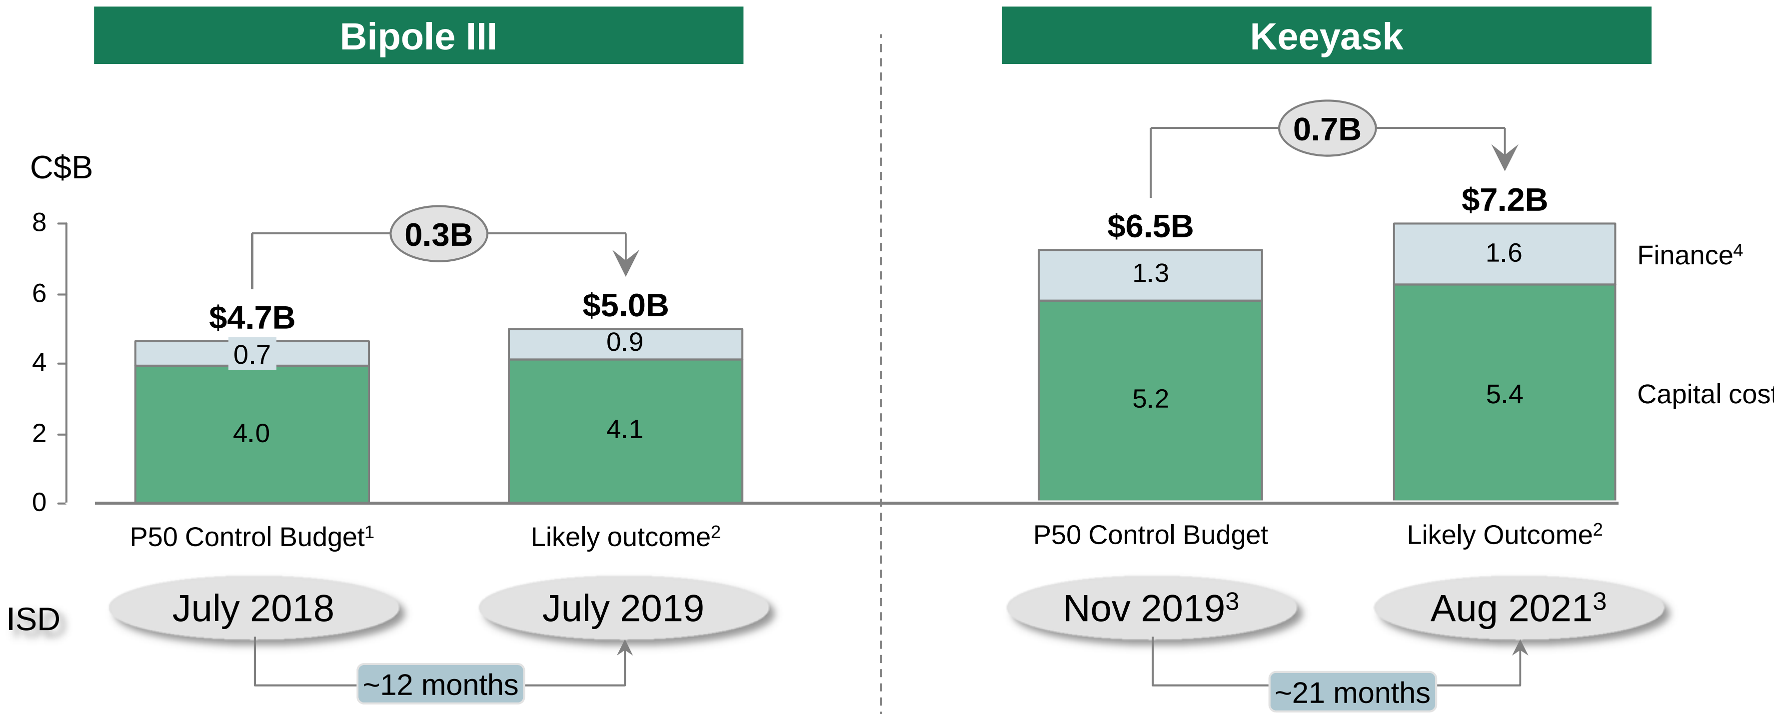
And remain sensitive to key uncertainties

		BCG view on assumptions
Water flows / Hydro risk	**Hydro risk influences total supply which drives opportunity sales** • 102 scenarios various sequences of drought and flood time periods • Climate change not explicitly modeled (impact unclear)	*Range of uncertainty unchanged*
Export prices	**Revenues sensitive to fluctuations in export price levels:** • Reference scenario below previous forecasts	*Adverse movement in MISO*
Capital Execution	**Cost and schedule overruns at one or both large projects can lead to increased borrowing and deterioration of capital profile:** • Scenarios modeled for cost and schedule overruns at Keeyask and Bipole	*Adverse movement in both projects*
Interest rates	**Canadian long-term interest rates influence MH borrowing costs** • +/- 100 bps change	*Favorable movement from NFAT to today*
Domestic Rates	**Domestic rates increases influence how quickly MH recoups its capital investments:** • 3% vs. 4% vs. 5% annual growth rate	*Range of uncertainty unchanged*
Net domestic demand	**Revenue and export quantities sensitive to domestic demand:** • Three levels considered: P50 (base) vs. P90 (high gross demand) vs. P10 (lower gross demand)	*Range of uncertainty unchanged*

Note: Exchange rate sensitivity limited given the company's internal FX net position, therefore there was no specific sensitivity analysis performed
Source: Manitoba Hydro

Exhibit 27: Capital cost & project schedules have deteriorated

~$1.0B in additional capital, ~12 month delay for BPIII and ~21 month delay for Keeyask



Transmission line construction productivity in winter main driver of schedule – 17% more than baseline must be completed in two remaining seasons

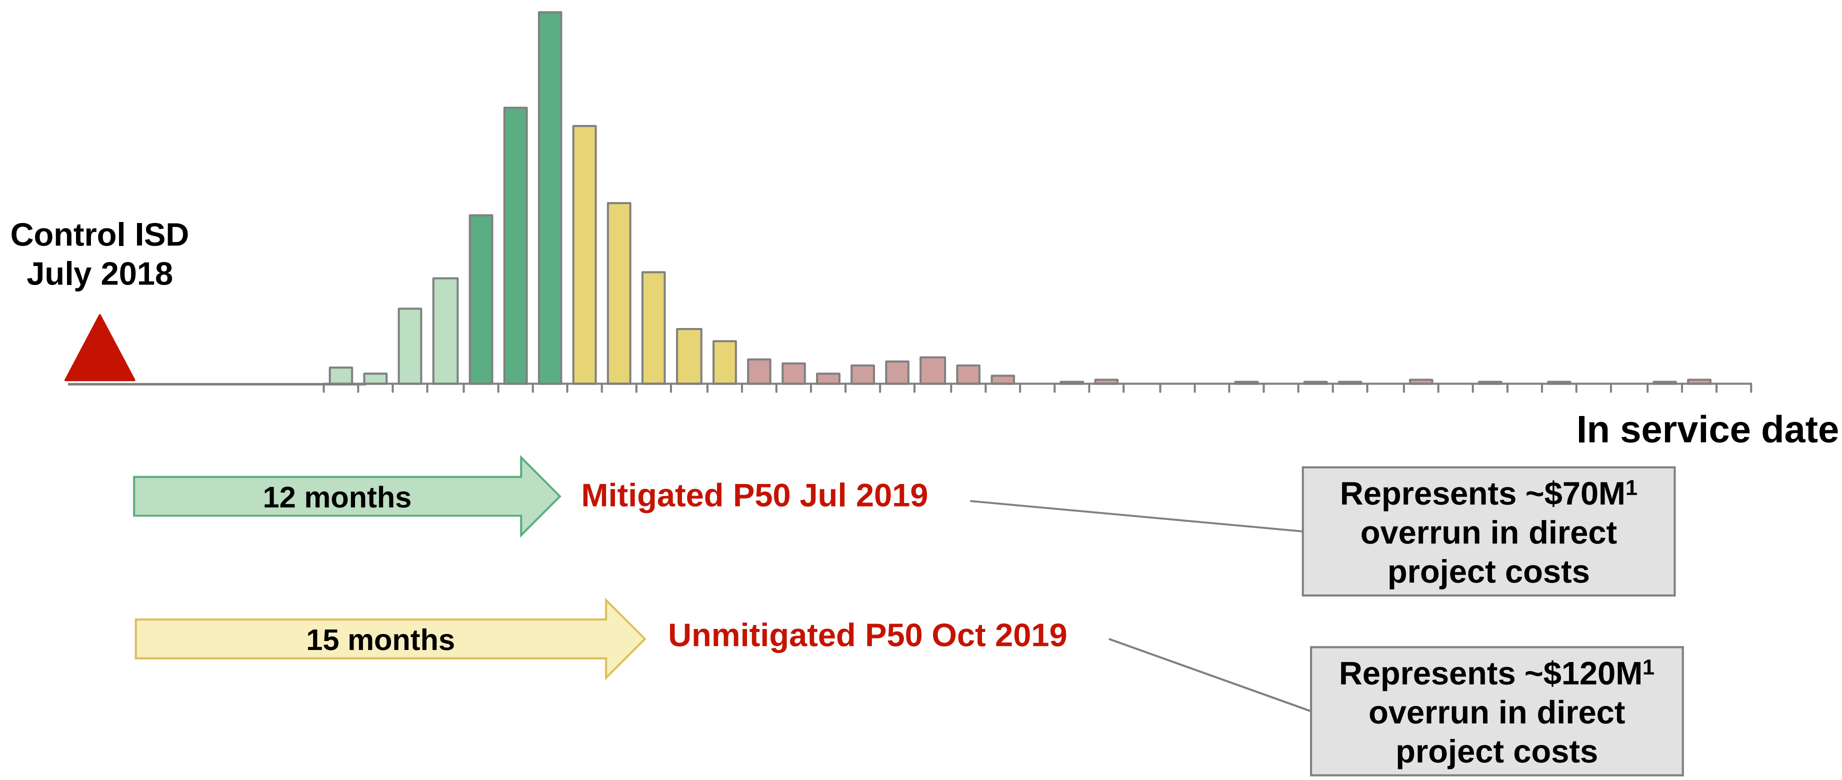
Loss of 1 complete summer construction season likely due to GCC contract underperformance, especially related to earthworks (at ~70% vs target) and concrete productivity (at ~40% vs target)

Sources: 1. Manitoba Hydro control budget. 2. BCG Analysis 3. First unit ISD 4. Includes interest & escalation

Exhibit 28: Bipole III 12 month delay is the most likely outcome

Bipole III ISD distribution

Based on current performance to date incorporating schedule mitigation activities



1. Excludes interest (Additional $0.2B in finance costs)
Note: This is based on mitigated estimates (August 15, 2016). Based on 1000 simulation runs
Source: MH durations estimates

Exhibit 29: Mitigated project delay expected to be ~21 months

Estimated in-service cost equal to ~$7.2B

Keeyask schedule distribution

Control ISD
Unit 1: Nov 2019

21 months — **Mitigated P50 Aug 2021**

Represents ~$0.4B[1] overrun in direct project costs

32 months — **Unmitigated P50 Jul 2022**

Represents ~$0.6B[2] overrun in direct project costs

1. Excludes interest (Additional $0.3B in finance costs)   2. Excludes interest (Additional $0.7B in finance costs)
Note: Activity durations and mitigation plans determined in conjunction with Manitoba Hydro. Based on 10000 simulation runs on 12-Aug-2016
Source: MH durations estimates. BCG analysis

Exhibit 30: Expected case $250M over control budget (incl interest), assumes some acceleration of construction

All numbers in nominal C$ B

	Control Budget P50	Current performance without mitigation (Downside case)	Mitigated schedule (Base case)
Spend to date	**1.8**	**1.8**	**1.8**
Transmission Line	0.6	1.1[2]	1.0
Converter Stations	1.1	1.2	1.2
Collector Lines	0.1	0.1	0.1
Community Development Initiative	0.0	0.0	0.0
Contingency	0.35	-	-
Escalation	0.2	0.1	0.1
Total project capex (excl interest)	**4.1**	**4.3**	**4.2**
Interest on incremental overrun	-	0.2	0.2
Interest on Control Budget P50 project cost	0.5	0.5	0.5
Total interest capex			
Total project capex (incl interest)	**4.65**	**5.0**	**4.9**
% of P50 control budget	**100%**	**108%**	**105%**
Schedule over run (months)	-	15 months	12 months
Project completion	July 2018	October 2019	July 2019

Excludes capitalized interest

~$15M/mo burn rate[1] for delay

Changed escalation rate reduces costs

*Potential **~$50-100M savings** through mitigations to manage schedule overrun. Preliminary est. of mitigation cost = $8M*

1. $15M/month burn rate applied to 12 months for Downside case and 9 months for mitigated case, with the remaining overrun charges relating to internal costs of the commissioning team and scaled down T-Line and Converter Station teams as needed. Includes $350M contingency allocation in addition to burn rate 2. Number rounded up to nearest billion

Source: MH control budget, CEF 2015, BCG analysis

Exhibit 31: Fully loaded project cost overrun forecast ~$700M

~$250M project capex benefit from schedule mitigation activities

(All numbers in nominal C$ B)	**Control Budget P50**	**Current trajectory without mitigation**	**Mitigated schedule**
Spend to date excl interest[1]	**2.1**	**2.1**	**2.1**
Generating Station (to-go)	2.4	3.3	3.1
Generating Outlet Transmission (to-go)	0.2	0.2	0.2
Contingency & Reserves (remaining)	0.3[2]	-	-
Escalation (total)	0.2	0.2	0.2
Total project capex (excl. interest)	**5.2**	**5.8**	**5.6**
Interest on incremental overrun[3]	-	0.7	0.3
Interest on Control Budget P50 project cost	1.3	1.3	1.3

Total project capex (incl interest)	**6.5**	**7.8**	**7.2**
% of P50 control budget	**100%**	**120%**	**111%**
Schedule over run (months)	-	32	21
Unit 1 ISD date	November 2019	July 2022	August 2021

*Potential **~$250M benefit** from mitigations and avoided interest*

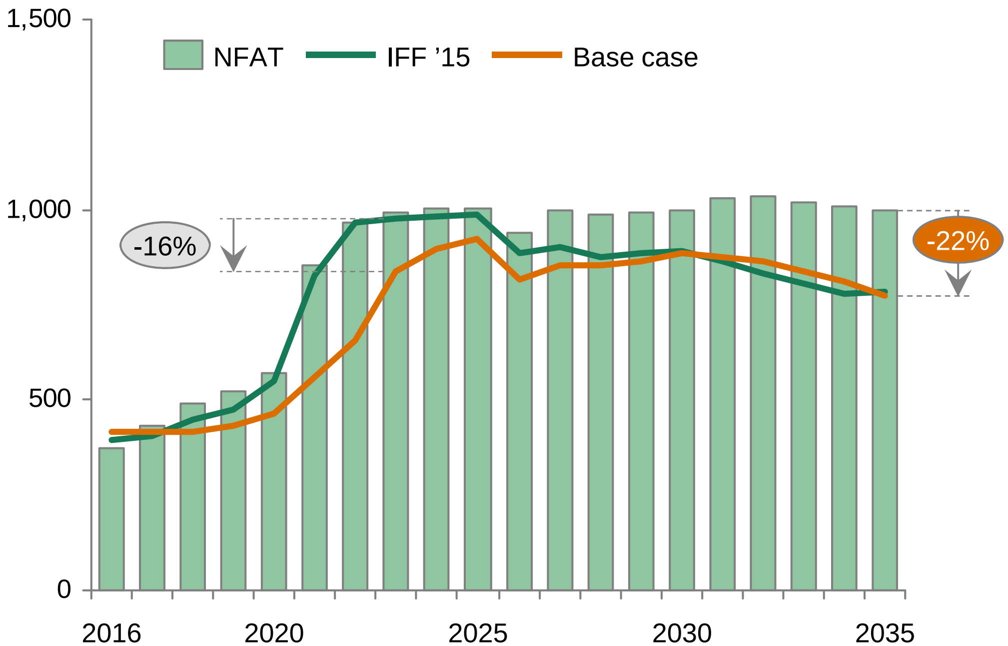
1. As at March 2016. 2. Original cont./reserves of $0.7B for project costs already partially allocated to contracts – $0.3B remaining. Assumed will be used up completely for overruns 3. Includes compounding effect due to schedule delay + additional interest on incremental project spend.
Note: Cost over run in fixed price, milestone based contracts (mainly equipment supply & install) reduced from previous phase due to greater certainty on risks (e.g. GGH contracts >50% complete, better SPI=0.94 vs 0.7 from previous phase on T&G, etc)
Source: MH control budget, CEF 2015, BCG analysis

Exhibit 32: Keeyask delay and low export prices impact revenue

Reducing latest forecast of export revenues by 19-28%

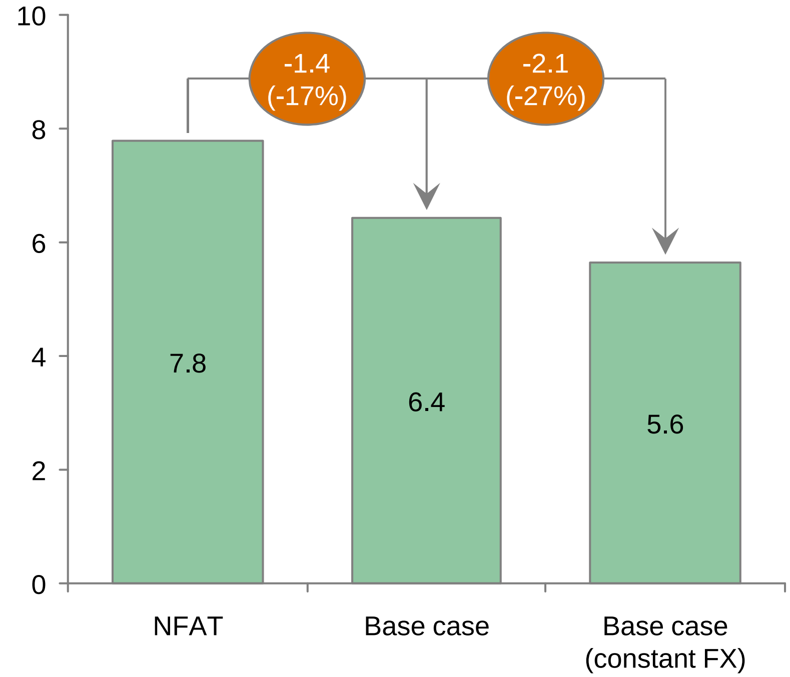
Export revenue forecasts have been revised downward since NFAT

Export Revenues ($C M)



Expected export revenues reduced by 19% to 28%

2017-2026 Total Export Rev. ($CB)



Secured firm contracts (30% of revenue[1]) reduce further downside; upside expected in case of Clean Power Plan approval

1. Including current contracts and term sheets, but not available uncommitted firm energy which could be contracted (17% of revenue).

Source: Manitoba Hydro, BCG analysis

Exhibit 33: Expected case equity ratios sustained at <15% through 2030

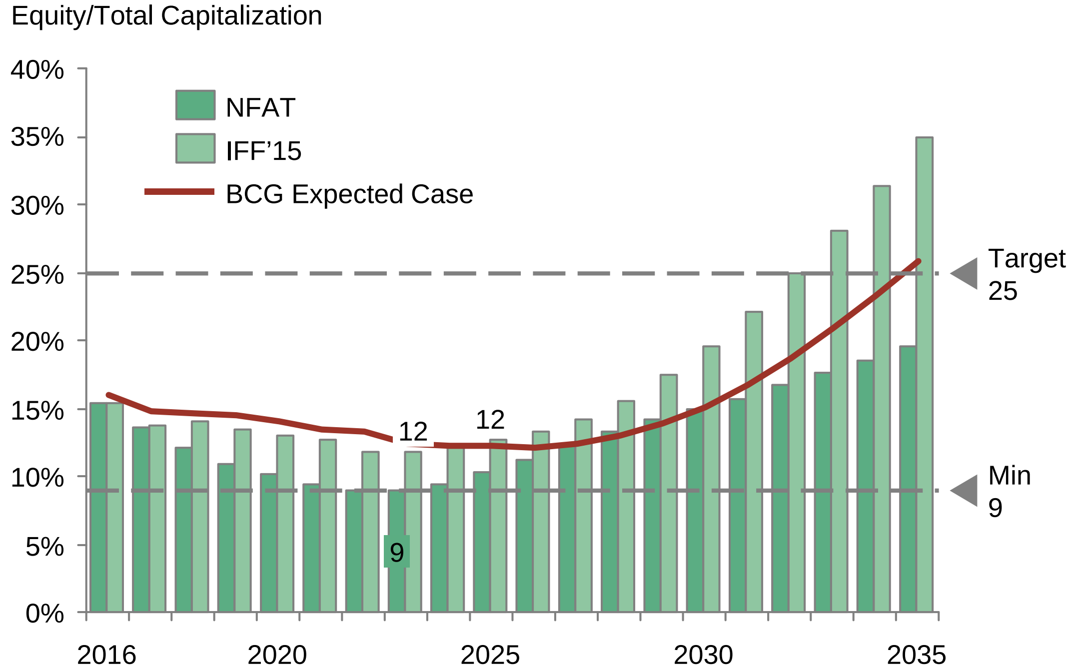
Key assumptions

NFAT
- Bipole in '19, Keeyask in '21, Tie-line in '20
- Level 2 DSM
- 2013 Interest rates

IFF '15
- Unchanged ISDs
- Reduced export price and slightly reduced demand
- Lower, 2015 interest rates

BCG Expected Case
- 12 mos. Bipole III delay
- 21 mos. Keeyask delay
- $1B total cost overrun
- Lower, 2016 reference export prices
- Lower, 2016 interest rate forecasts

Projected ratios have decreased materially under revised capital and price assumptions



Additional risks

- Additional project CapEx overrun
- Further export price deterioration
- Hydro risk
- Increasing interest rates
- Lower domestic rate increases

Exhibit 34: Stress test shows significant impact if further downside risk experienced – equity % dips to low single digits

Downside scenario modelled

Water flow	Low flow scenario
Capital project overruns *Schedule (months)*	Keeyask: 32mth delay BPIII: 15mth delay
Interest rates *Long range forecasts*	ST~3.85% LT ~5.4%
Export prices	Peak and off peak spot curve as per IFF'16 (no premium and reduced base)
Cost inflation *Overall OM&A cost increase*	2% in 2016-17 3.5% pa 2018 - 2021

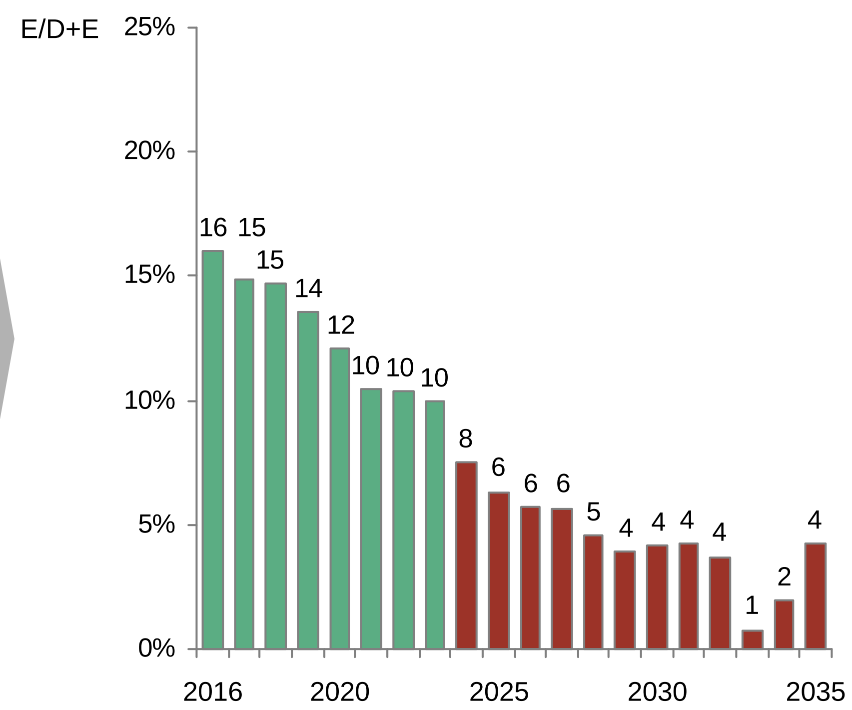


Exhibit 35: Can the projects be stopped / paused?

Bipole III and Keeyask are already well advanced in their construction with $5B already sunk

- Bipole III $2.5B (53%) spent of $4.7B control budget
- Keeyask with $2.5B (39%) of $6.5B control budget spent, including completion of milestones that prevent contractual cancellation

Cancelling Bipole III and Keeyask would bring total spend up to ~$7B

- In addition to sunk costs, Bipole III and Keeyask would both incur cancellation costs (e.g., breakage, remediation) of ~$1B each
- Decision to just cancel (or reroute) Bipole III would strand Keeyask, making it uneconomic and likely trigger cancellation
- Implication of cancelling both projects is ~$7B capital spent without completion of any functioning assets

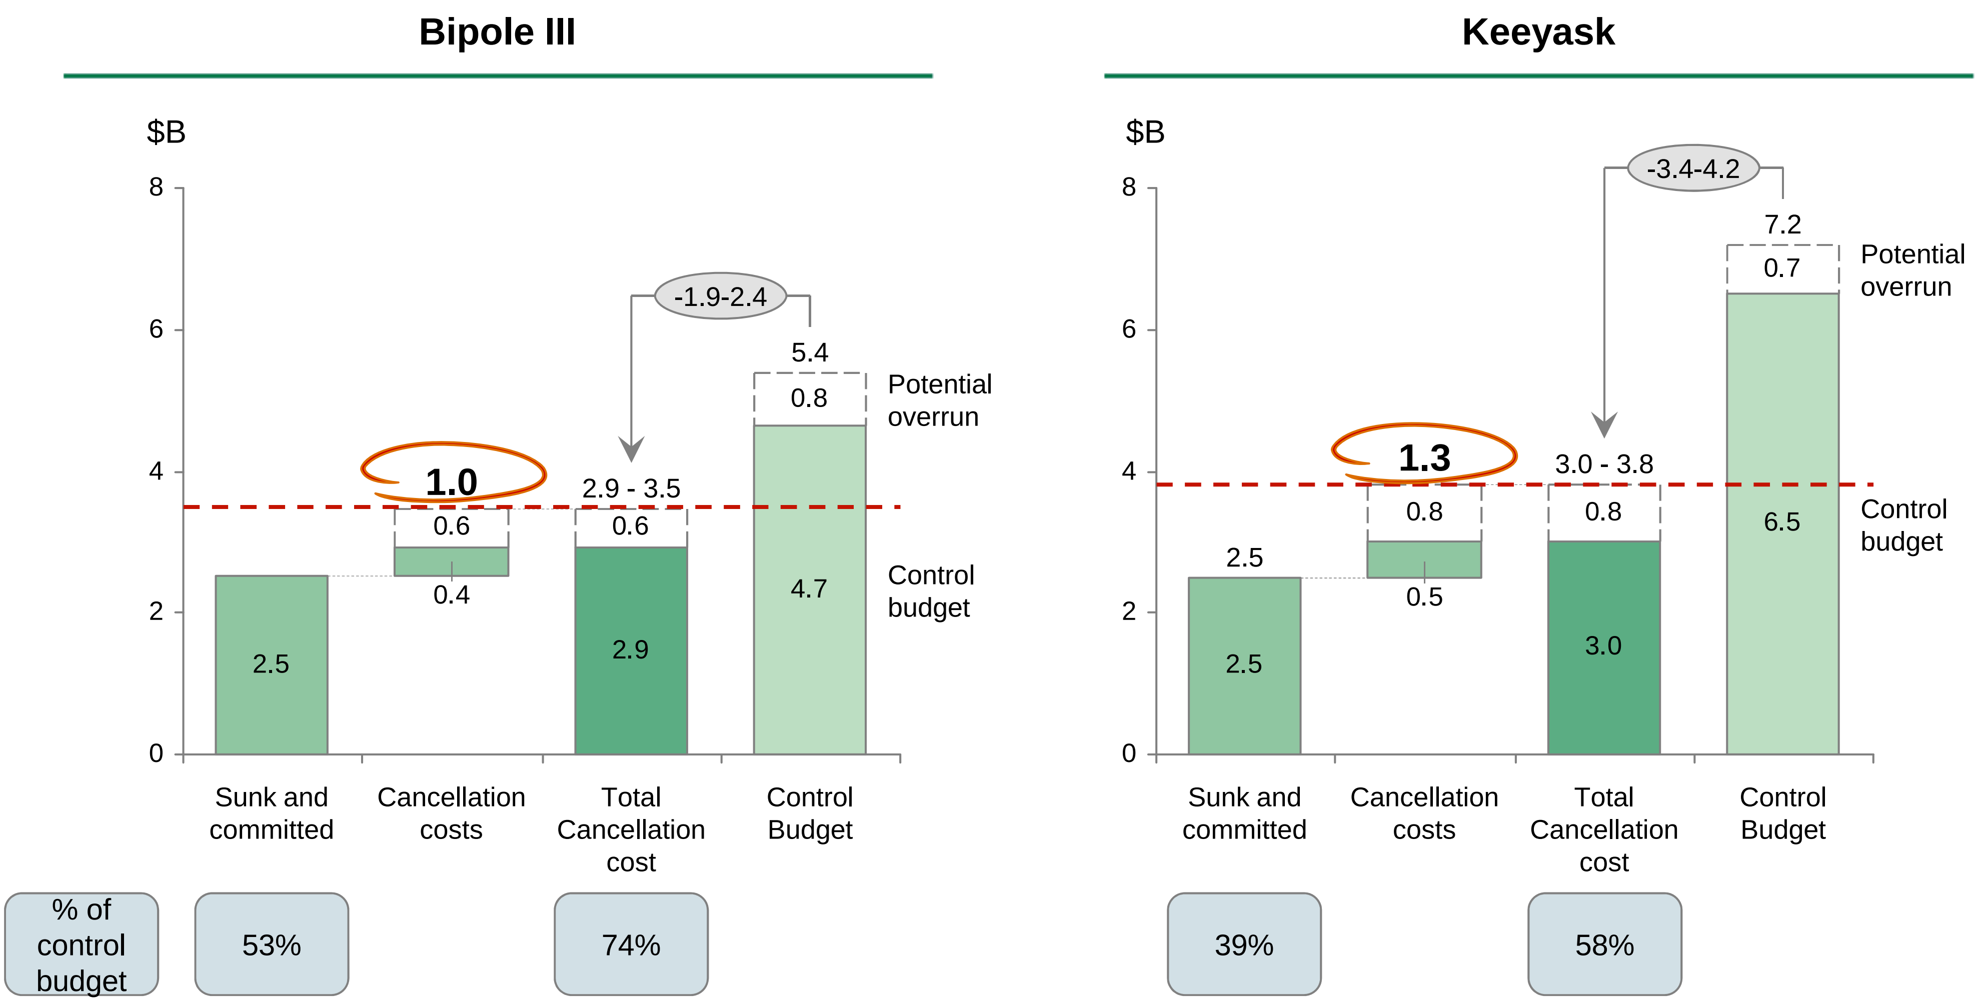
Economics remain in favour of continuing both projects when compared to alternatives

- ~$3.2B cost to complete Bipole III <u>West</u> clearly more favourable vs. ~$4.5B rerouting costs of Bipole III <u>East</u>
  - Construction cost of Bipole III <u>East</u> ~$3.0-3.5B on top of ~$1B Bipole III <u>West</u> cancellation costs
- $4.7B cost to complete Keeyask yields an NPV $3-5B more favourable vs. switching to gas option
  - Gas option with incremental $11.9B spend (including cancellation and capitalized cost of gas supply)

Further, several strategic risks to consider for stopping or pausing Keeyask

- Considerable trust and relationship damage with four First Nations partners likely to impede any future Hydro project
- Market risk of inability to supply MISO plus requirement to add domestic reserve
- Direct GDP impact of ~0.5%, particularly impacting First Nations communities

Exhibit 36: Cancellation of either project brings to bear significant further cost



Source: Manitoba Hydro estimate of cancelation; BCG analysis

Exhibit 37: Strategic impacts of cancellation potentially severe

Bipole III: Major risks relate to future reliability

- Continued system reliability risk: failure at Dorsey C.S. or on Bipole I or II will jeopardize the Province's energy supply
- Limited capacity and decreasing operational reliability on BP I & II
- Cancellation or rerouting of Bipole III strands Keeyask and likely implies cancellation due to deterioration of economics

Keeyask: Significant stakeholder impacts

- Considerable trust and relationship damage with four First Nation partners likely to impede any future Hydro project – social license to operate many years in the making
- Market risk of inability to supply MISO plus requirement to add domestic reserve
- Direct GDP impact of ~0.5%, particularly impacting First Nations communities

Source: Manitoba Hydro estimate of cancelation; BCG analysis

Exhibit 38: Completing Bipole III is the best go-forward option

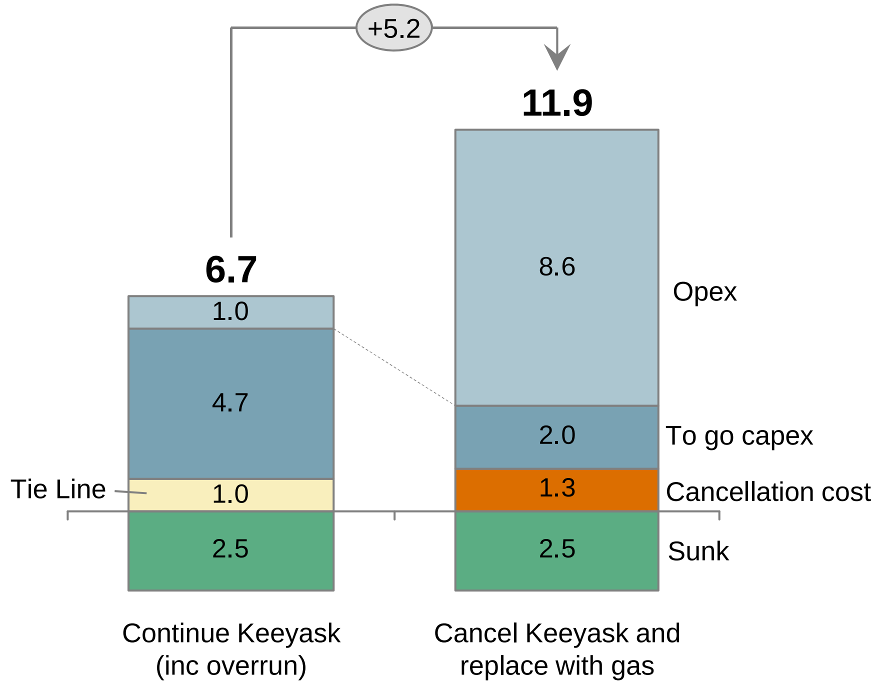
Shifting to the east route would be more costly and require at least 5 years for approvals

	Go Forward Option	Verdict	Rationale	Incremental Cost	Likely ISD
	Cancel Bipole III West	✗	• System still lacks redundancy and exposed to major outage risk • Strains relationship within MISO and risks exports	• **$400M to $1B** to cancel, wind-down and remediate	• N/A – no solution implemented
Selected option	**Continue Bipole III West**	✓	• Fastest way to improve reliability • Supports Keeyask and future hydro generation	• **$2.2 – 3.2B** to complete	• 2018 – 2019
	Shift to East Route	✗	• More costly with later in-service date • Negative environmental and First Nations impacts along east route	• **~$3.4 -4.5B+**, (~$2.3 – 3.4B for new East route work)[1]	• 2025 – 2026
	All-Gas	✗	• Future input price volatility (gas, imports) • Loss of export revenue through lack of capacity for new Keeyask power • Damage to relationships with US partners and First Nations groups	• **$3.4-4.1B**[2] (NPC[3] of gas + Bipole III cancellation + addt'l O&M)	• 2021 – 2022
	Import + Gas	✗		• **$4.9-5.5B**[4] (capital cost + Bipole III cancellation)	• 2021 – 2022

1. Assumes some work on collector lines and convertor stations continues. Estimate is purely factored at low levels of maturity 2. Based on MH and BCG scenario analysis, with contingency and over-run factors applied 3. NPC = net present cost 4. Capital cost from Manitoba Hydro Bipole III EIS + BCG analysis of Bipole III cancellation cost

Exhibit 39: Economically, continuing Keeyask is most attractive option

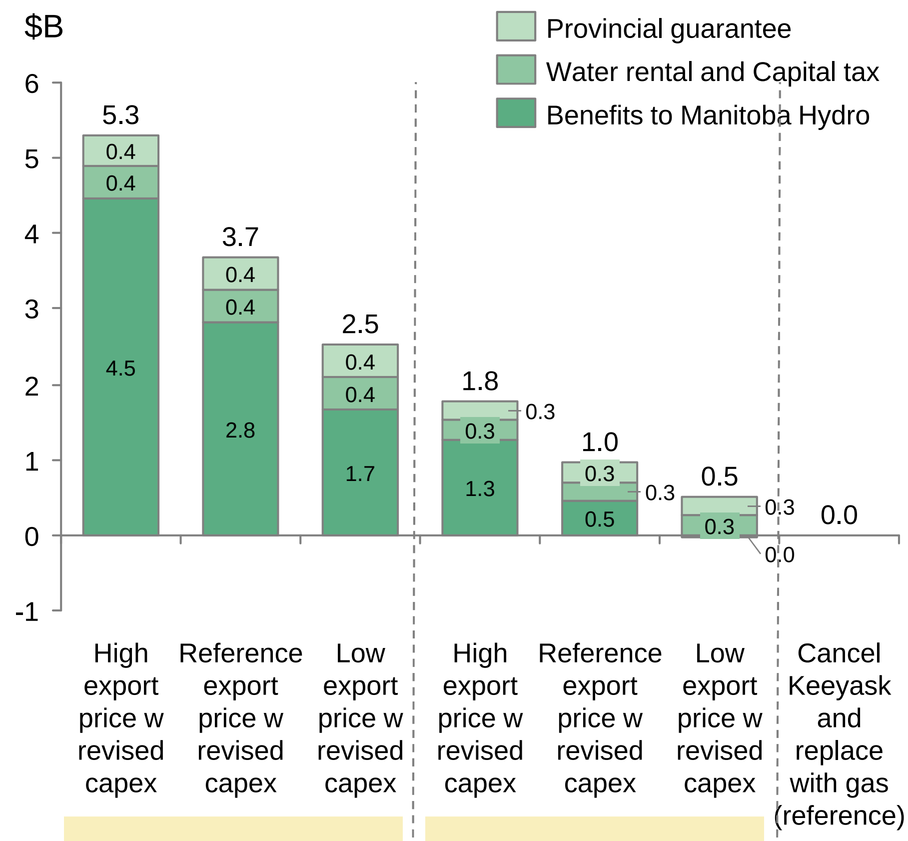
Forward capital and operating cost of gas vs Keeyask is ~$5B higher



Hydro = High upfront capital, low, stable opex

Gas = Low upfront capital, high, volatile opex

Relative NPV of continuing is $3-5B greater than replacing with gas



Base assumption @4.15% real disc rate

Sensitivity @8.0% real disc rate

Tab 29

CAC/MH II-47

Subject: Capital Expenditures
Reference: PUB/MH I-90 c)

a) The response to part (c) makes reference to a risk assessment associated with the consequences of a capital project's deferral. Is such an assessment undertaken for each project? If so, please provide risk assessment for each project in CEF11 with total costs of $100 M or more.

ANSWER:

A risk assessment associated with the consequences of a capital project's deferral is not undertaken for each project. Please see Manitoba Hydro's response to CAC/MH II-47(b) for additional information.

CAC/MH II-47

Subject: Capital Expenditures
Reference: PUB/MH I-90 c)

b) Is there a formal process/framework for assessing the relative risks of various capital projects? If yes, please provide the assessment underlying the projects set out in CEF11.

ANSWER:

The Capital Project Justification ("CPJ") framework is used to summarize technical, economic and financial information for a project that is being proposed or revised for inclusion in the capital program. Information provided in the CPJ includes the business case, risk assessment, resourcing requirements and other pertinent details.

The Justification section of the CPJ provides the rationale for proceeding with the project, including the reasons why the selected option was recommended, the degree of urgency and how the project supports corporate and specific business unit goals and plans. This section also addresses efficiencies that may be lost or negatively impacted as a result of deferral.

The Risk Analysis section of the CPJ addresses any unusual or special risks associated with proceeding with the recommended alternative. Risks can include scheduling, resourcing, construction uncertainties, with or without financial impacts.

The Summary of Alternatives section summarizes the alternatives studied including the most significant criteria and why the recommended alternative was selected. It includes an economic comparison of the costs and benefits for each alternative.

The purpose of the CPJ is to provide management with information to review and evaluate the technical merits and economic justification for a project. Proposed CPJ's are reviewed and approved by Executive Committee and actions are taken where necessary to mitigate risks and address prioritization.

The prioritization of the overall capital portfolio considers safety, reliability, customer requirements, compliance with regulation, environmental and financial impacts including risk of deferral. Varying methods of prioritization are used by the business units to assist the Executive in making decisions for the allocation of capital dollars and resources including the use of asset condition assessments and ranking tools to evaluate projects using common criteria.

CAC/MH II-47

Subject: **Capital Expenditures**
Reference: **PUB/MH I-90 c)**

c) If not, what process is used to prioritize capital projects and how are the risks associated with each project taken into account?

ANSWER

Please see Manitoba Hydro’s response to CAC/MH II-47(b).

			ORIGINATING

Project Description
An 800 km, ±500 kV dc transmission line is constructed between the proposed Bipole I and II emergency paralleling site near Radisson and the proposed Riel site. A dc paralleling line is constructed between the proposed Riel site and Dorsey Station to provide HVDC transmission during an Interlake corridor loss. Before Bipole III is in service, the new line will be used for Bipole II and the existing Bipole I & II lines are paralleled for Bipole I, resulting in loss savings of about 78 MW at maximum generation.

Recommendation
Build an 800 km, +/-500 kV dc transmission line between the proposed Bipole I and II emergency paralleling site near Radisson and the proposed Riel site, and build a dc paralleling line between the proposed Riel site and Dorsey station.

Project Scope
Includes the 500 kV dc transmission line from near Radisson to Riel, and a paralleling line from Riel to Dorsey.

Background
This project is being recommended based on the economics of up to 78 MW of HVDC transmission power loss savings and reliability benefits discussed in the report, Manitoba Hydro Transmission System Reliability and Enhancement Options, which will be released in the fall of 2001.

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals
This transmission only alternative provides increased reliability to the Manitoba Hydro system. In normal steady-state operation, this item provides an increase in southern power of about 78 MW at full load due to decreased HVDC transmission losses.

ANALYSIS OF ALTERNATIVES:

Economic Analysis		
Discount Rate	10%	

Recommended Option	NPV
800 km, ±500 kV dc transmission line is constructed between the proposed Bipole I and II emergency paralleling site near Radisson and the proposed Riel site.	zero

Other Alternatives Considered	NPV

Other Alternatives Considered	NPV

Risk Analysis

Risk Analysis was documented in System Planning and Resource Planning and Market Analysis joint report on Manitoba Hydro Transmission System Reliability and Enhancement Options.

RESOURCE REQUIREMENTS AND CAPITAL BUDGET ESTIMATE:

Resource Requirements

Total Budget

2002/03	$ 2,500,000
2003/04	$ 4,586,000
2004/05	$ 13,063,000
2005/06	$ 13,533,000
2006/07	$ 12,269,000
2007/08	$149,096,000
2008/09	$ 46,111,000
2009/10	$ 62,373,000
2010/11	$ 57,248,000
Total	$360,779,000

Proposed Schedule

Work start date: 2002/04/01
In service date: 2010/10/31

Related Projects

SECTIONALIZATION OF LINE D602F AT RIEL

Reference Documents

This project is recommended in the report, Minimum Transmission Requirements for HVDC Bulk System Reliability, which also recommends Sectionalization of the 500 kV line D602F at Riel.

These two projects are the first recommendations to which come out of

Reference Documents

the work associated with the report, Manitoba Hydro Transmission System Reliability and Enhancement Options, which will be released in the fall of 2001.

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).
Henday-Riel ±500 kV HVDC Line

Recommendation (This section is required for all Addendums).
Change the location of the northern termination of the dc transmission line, from Radisson to Henday, thereby increasing the line length by 20 km for a revised length of 820 km. The revised total net cost of the complex is now $360,161,000, an increase of $8,245,000 over the previously approved budget.

Project Scope (This section is be filled out only if there is a change to the scope).
Build an 820 km, ±500 kV dc transmission line between Henday and the proposed Riel site, rather than an 800 km line between Radisson and Riel.

Background (This section is be filled out only if there is information relevant to the recommendation).
The original northern termination of the line at a remote site near Radisson was consistent with an earlier plan to locate the Bipole III rectifier at the future Gull generating station site. Further studies have resulted in a recommendation that the Bipole III rectifier be located at the future Conawapa generating station site, since it is more consistent with the ultimate 2000 MW rating of Bipole III. The HVdc Task Force at the May 9, 2003 meeting approved this recommendation. Since the Bipole III HVdc line was justified based on loss saving while connected to Bipole II, the line presently only needs to be built to the Bipole II rectifier site at Henday. The line would then be extended to the Conawapa generating station site when the Bipole III converters are installed at that site. The future location of the Bipole III rectifier at Conawapa can still accommodate a possible Gull generating station first generation development sequence.

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals (This section is be filled out only if there is a change to the recommended alternative).
The termination of the Bipole III HVdc line at Henday reduces the risk associated with outages of the Bipole I & II HVdc lines, because the connection of Bipole I & II converters to the Bipole III line can be done in a staffed station with switches, rather than at a remote location with manual connections made by a line crew. The termination of the Bipole III HVdc line at Henday does not lead to the risk of all three HVdc lines crossing at one point, which is a difficult and expensive risk to mitigate.

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).
Henday-Riel ±500 kV HVDC Line

Recommendation (This section is required for all Addendums).
The extended environmental process has resulted in a delay in the expected license date by two years and thus it is recommended that the in-service date be delayed by two years from 2010 10 to 2012 10.

Project Scope (This section is be filled out only if there is a change to the scope).

Background (This section is be filled out only if there is information relevant to the recommendation).

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals (This section is be filled out only if there is a change to the recommended alternative).

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis		
Discount Rate	For current corporate rates see G911 %	For clarification on hurdle rates, contact Economic Analysis Department

Recommended Option	**NPV (= PV of BENEFITS - PV of COSTS)**

Other Alternatives Considered	**NPV (= PV of BENEFITS - PV of COSTS)**

Risk Analysis - (This section is be filled out only if there is a change to the project risk).
The Henday-Riel ±500 kV HVDC Line provides additional southern generation through loss savings, and also a reliability benefit to the Manitoba Hydro system. Any delay to the ISD means additional risk to the system for the duration of the delay. Riel station and Bipole III share common elements, so the environmental strategy must be considered as a whole.

RESOURCE REQUIREMENTS AND CAPITAL BUDGET ESTIMATE:

Resource Requirements (This section is be filled out only if there is a change to the resource requirements).

Total Budget - (This section is required for all Addendums).

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III with the HVdc line routed west of Lakes Winnipegosis and Manitoba.

Recommendation (This section is required for all Addendums).

Manitoba Hydro has been asked to look at other alternatives for routing the Bipole III transmission line from the east side of Lake Winnipeg. In the interim, a west side of the province (west of Lakes Winnipegosis and Manitoba) routed Bipole III transmission line from Conawapa Station to Riel Station with 2000 MW of HVdc converters at both stations is being advanced as a placeholder in the budget. In October 2006, a recommendation for an alternative to the east-side of Lake Winnipeg routed Bipole III line for Manitoba Hydro system reliability will be made. Also, the recommendation will address the reliability of equipment associated with common mode HVdc station outages in addition to common mode outages of the HVdc lines. The October 2006 recommendation may be quite different from the above.

Project Scope (This section is be filled out only if there is a change to the scope).

The Bipole III scheme as a placeholder in the budget includes:

- An HVdc transmission line of a minimum length of 1295 km from Riel Converter Station to Conawapa Converter Station.
- A converter station with 2000 MW of converters at Conawapa.
- Six ac transmission lines approximately 30 km long to connect the Conawapa Converter Station to Henday Converter Station (three of these lines are not necessary with Conawapa generation development).
- A converter station with 2000 MW of converters at Riel, including 3 synchronous compensators

A paralleling line between Dorsey Converter Station and Riel Converter Station is not required as paralleling with Bipole II will not be possible and the western-routed Bipole III line will not be usable by Bipole I or Bipole II.

Background (This section is be filled out only if there is information relevant to the recommendation).

A Bipole III transmission line routed on the east side of Lake Winnipeg was originally recommended and approved (I.M. Node Number 1.5.1.2.2.1). The Board of Manitoba Hydro has directed that alternative transmission line (Bipole III) routes other than the east side of Lake Winnipeg be evaluated.

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals (This section is be filled out only if there is a change to the recommended alternative).

Due to the severe critical risk to the Province and Corporation of not mitigating an Interlake (Bipole I&II) corridor outage or a Dorsey station common mode outage, this budget item is being included as a placeholder pending an October 2006 recommendation of an alternative to an east-side of Lake Winnipeg routed Bipole III line.

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis		
Discount Rate	For current corporate rates see G911 %	For clarification on hurdle rates, contact Economic Analysis Department

Recommended Option	NPV (= PV of BENEFITS - PV of COSTS)

Other Alternatives Considered	NPV (= PV of BENEFITS - PV of COSTS)
An East-side routed Bipole III line.	

Risk Analysis - (This section is be filled out only if there is a change to the project risk).

The risks associated with this project are as follows:

1) Technically inferior solution to the eastern-routed Bipole III line with converters; less load served on average in situations for which the line is to be built.
2) Less reliable solution since the west side scheme would still only provide an outlet of 2000 MW of northern generation in the event of another Bipole I&II corridor outage, while an east side Bipole III line would allow the paralleling of Bipole I&II converters on the Bipole III line providing the outlet of 3300 MW of northern generation. Also the longer line length associated with a western route increases exposure to outages on Bipole III.
3) A delayed ISD over an eastern routed line, placing Manitoba customers at greater risk for a longer period of time. A western line will likely take longer for conducting environmental assessment/public work consultation and will take more time to build. The earliest date for initiation of environmental work is after the October 2006 recommendation of an alternative to the east of Lake Winnipeg Bipole III line.
4) Justification at a public hearing by Manitoba Hydro of the westerly routing concept vs. an easterly route concept will be problematic.
5) Although 1265 km is used as a proxy minimum for the line length, it is likely the actually built line will be considerably longer with more cost and losses, due to efforts to maximize separation from the existing HVDC right of way.
6) The siting of Bipole III in a western corridor would make the placement of the next north/south transmission line very problematic with the east of Lake Winnipeg routing being blocked and the Interlake routing presenting significant risk of a common mode outage.

There is a risk of further delays in the expected in-service date as the siting of the southern station at Riel may need to be re-evaluated with a western routing of Bipole III

RESOURCE REQUIREMENTS AND CAPITAL BUDGET ESTIMATE:

Resource Requirements (This section is be filled out only if there is a change to the resource requirements).

To be determined.

Total Budget - (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Approved CPJ Budget	Current CEF Budget	Revised CPJ Budget	CPJ Increase (Decrease)	CEF Increase (Decrease)
Prev.	$ 2,571	$ 2,571	$ 2,571	$ 0	$ 0

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).
Bipole III with the HVdc line routed west of Lakes Winnipegosis and Manitoba.

Recommendation (This section is required for all Addendums).
Increase the proposed budget for the Bipole III western route budget placeholder by $367,940,000 to $2,247,835,000.

Project Scope (This section is be filled out only if there is a change to the scope).
No Change.

Background (This section is be filled out only if there is information relevant to the recommendation).

The estimate is higher due to:

- an increase in line length for the western route as refined for the October 2006 report, from 1296 km to 1341 km;
- moderate increases being experienced in transmission line material costs due to price volatility in the marketplace (approx. 20%);
- considerable increases being experienced in transmission line construction costs, doubling since Addendum #04 due to market conditions (approx. 40% increase applied in late 2005 due to factors such as increased labour and fuel costs, and a further 50% increase applied in 2007 due to recent experience with tendered prices for the Wuskwatim-Birchtree transmission line and further upward trends in construction costs across western Canada), and
- resultant increases in interest and escalation.

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals (This section is be filled out only if there is a change to some aspect of the recommended alternative).
No Change.

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III Western Route 500kV HVdc Transmission Line & 2000MW Converters

Recommendation (This section is required for all Addendums).

Increase the budget for the Bipole III complex by $1706 million to a revised total of $3954 million, in order to incorporate the following:

- review of estimates for all components of the complex (total increase of $739 million to the base estimate, 2009$),
- inclusion of contingency for all components of the complex (total increase of $525 million to the base estimate, 2009$), and
- the resultant changes to interest and escalation (increase of $442 million).

Project Scope (This section is be filled out only if there is a change to the scope).

No change to the high-level concept at this time. Potential future changes to scope (cost and schedule) that may be forthcoming in a subsequent CPJ Addendum (i.e., are not part of this submission) are as follows:

- Changes to the existing transmission network or at existing generation facilities that may be necessary as a result of the Bipole III transmission line and converters being added to the system.
- Changes that may be necessary for an HVdc transmission line and converters rated at 2500MW.
- Application of Transmission Development Fund (TDF) and/or Adverse Effects policies that may be recommended for the Bipole III complex.

Background (This section is be filled out only if there is information relevant to the recommendation).

CPJ Addendum #04, submitted in April 2005, was the first introduction to the Capital Expenditure Forecast of a western-routed 500kV HVdc transmission line with 2000MW of converters. The budget submitted with CPJ Addendum #04 was a placeholder only, pending completion of studies by System Planning, and was based on a 2001 estimate prepared by Teshmont Consultants.

CPJ Addendum #05, submitted in May 2007, addressed an increase of 45km to the length of the transmission line, as well as increases being experienced in transmission line material and construction costs due to market prices. The cost of licensing, property and converters were not updated at that time, nor was contingency identified in that estimate.

This CPJ Addendum #06 covers re-estimates that have been prepared since either the 2001 Teshmont report or the May 2007 CPJ Addendum, for all components of the Bipole III complex. These re-estimates result in an increase of $739 million to the base estimate, detailed as follows (all amounts are in 2009$).

TRANSMISSION-RELATED ITEMS (total increase of $142 million to base estimate):

a) <u>500kV dc Transmission Line</u>
The base estimate for the transmission line has increased by $72 million due to a design change from double to triple conductor, in order to lower the surface field gradient to accepted worldwide practices and thus minimize flashovers, and by $25 million due to the application of the Transmission Line Agreement (TLA), or unionization of labour.

Background (This section is be filled out only if there is information relevant to the recommendation).

b) Northern 230kV Collector Lines
Reflects increases since 2001 to both construction material and labour costs ($23 million). Also reflects an increase of 39km to the overall length of transmission line construction required ($9 million). In addition, the line from Limestone to Conawapa, previously assumed to be established with the construction power for the Conawapa G.S, is now required first for construction power of the Northern Converter Station ($9 million).

c) Licensing & Environmental Assessment
Costs have increased by $2 million due to more comprehensive aboriginal and community consultations.

d) Sectionalize 230kV Transmission Line R49R at Riel
This is a new item, estimated at $2 million. R49R sectionalization is required to accommodate and reliably transmit a 2000MW Bipole III at Riel. This had been recommenced with the Riel Sectionalization project but was deferred to coincide with Bipole III converters.

In addition to the above, the risk assessment yielded a contingency estimate of $143 million (see the Risk Analysis section for details). These changes, along with an increase of $57 million for interest and escalation, make the total net increase equal to $343 million and the revised total net cost equal to $1477 million, for the transmission-related portion of the complex.

CONVERTER-RELATED ITEMS (total increase of $596 million to base estimate):

e) Riel Converter Station
Converter and HVdc equipment costs remain relatively unchanged; however, the costs for synchronous condensers have more than doubled. Studies have also recommended the addition of a fourth synchronous condenser for the 2000MW Bipole ($193 million combined increase). Other increases to the base estimate include: higher construction management, project management and engineering costs, which were not fully considered in the 2001 placeholder ($49 million); and increase in site size, development and infrastructure costs driven by safety and maintenance requirements, as well as additional facilities for fast drain and oil spill containment systems ($29 million).

f) Northern Converter Station at Conawapa
Converter and HVdc equipment costs remain relatively unchanged. Changes to the base cost are as a result of: inclusion of the construction camp previously assumed to be built and covered by the Conawapa G.S. Project ($38 million); higher construction management, project management and engineering costs not fully considered in the 2001 placeholder ($61 million), and site size increase of 2.2 times that assumed in 2001 and the associated increase in site development and infrastructure costs driven by safety and maintenance requirements, as well as additional facilities for fast drain and oil spill containment systems ($54 million).

g) Riel Site Development for Converters & 230kV Switchyard
Part of the switchyard will be established under a separate project, Riel Sectionalization; however, the concept was developed to more easily accommodate the future HVdc requirements (5 bays and 12 breakers vs. just 3 bays and 9 breakers) and reconfiguration to accommodate a transfer bus scheme, therefore 50% of the equipment costs are included in this estimate ($33 million). An expansion of the 230kV switchyard is required with Bipole III to output the 2000MW, establishing 4 new bays and 11 breakers, and required terminations for HVdc equipment are included in the base estimate ($51

Background (This section is be filled out only if there is information relevant to the recommendation).

million). Half of the site development costs at Riel are included here as attributable to the Converter Station and 230 Switchyard, whereas the 2001 report did not have any site development costs (assumed it would be developed at Riel prior to Bipole III). Like the northern converter station, the site size at Riel has increased (approx. 2.6 times) due to maintenance and security requirements, changes to oil spill containment systems, and planning the layout to accommodate for future additions to the station (i.e. paralleling line and additional 500kV and 230kV AC lines). The associated site development and infrastructure costs have increased ($28 million).

h) Northern 230kV Switchyard
Estimate has increased by $25 million to accommodate the following scope changes: two temporary additional AC lines required to transmit a 2000MW Bipole in the interval when Bipole III is in service before Conawapa G.S. (due to the change in generation sequence), and three lines for future Gilliam Island addition, for a total of 8 bays and 32 breakers.

i) Property for the Riel Converter Station
Not previously included in the estimate. Includes $6 million worth of station site properties and $12 million worth of buffer properties, all purchased from private owners.

j) Construction Power Station for Northern Converter
This item was not previously included, as it had been assumed to be part of the construction of the Conawapa Generation Station. Due to a change in sequencing this complex will be the first to require construction power, and hence the estimated cost of $15 million is now part of this complex.

k) Electrode Lines and Stations
Other components not previously included that have now been estimated are for the electrode lines and stations for both the Northern and the Riel Converter Stations, for a total of $2 million.

In addition to the above, the risk assessment yielded a contingency estimate of $382 million (see the Risk Analysis section for details). These changes, along with an increase of $384 million for interest and escalation, make the total net increase equal to $1363 million and the revised total net cost equal to $2477 million, for the converter-related portion of the complex.

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals (This section is be filled out only if there is a change to some aspect of the recommended alternative).

On July 4th, 2001 a System Planning report entitled "Minimum Transmission Requirements for HVDC Bulk System Reliability" (SPD 01/7) was issued and subsequently approved. A major recommendation of that report was for a Bipole III transmission line routed east of Lake Winnipeg. Converter capacity to be connected to the line would be considered in subsequent studies.

At the request of the MHEB, System Planning examined reliability alternatives to an eastern routed Bipole III line. The report entitled "Manitoba HVDC Reliability Alternatives" (SPD 2006/11) was issued on October 4th, 2006, and concluded that Bipole III routed west of Lakes Winnipegosis and Manitoba with 2000 MW of converter capacity was the leading reliability alternative to an eastern routed line.

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals (This section is be filled out only if there is a change to some aspect of the recommended alternative).

Based on the conclusions of this report, a recommendation was made by the Executive to the MHEB to proceed with Bipole III, routed west of Lakes Winnipegosis and Manitoba, and with 2000 MW of converter capacity.

Capital Investment Categorization:

Driver	Category	Sub-category	Split	Amount

Risk Analysis - (This section is be filled out only if there is a change to the project risk).

Contingency (total of $525 million in base 2009$):

The contingency estimate is based on risk assessments that were conducted to identify areas of uncertainty or potential fluctuation, and is detailed as follows:

TRANSMISSION-RELATED ITEMS (total contingency of $143 million or 15% of the base costs):

a) 500kV dc Transmission Line (total contingency = $116 million or 15% of the base costs)
   - A potential change to the detailed route selection or line length of up to 10%, as the final route has not yet been determined ($87 million).
   - Related to lack of geotechnical information, uncertainty with soil conditions calls for the purchase of extra foundation types to allow for flexibility during the tight construction window ($15 million).
   - Potential premiums in association with maximizing aboriginal content ($10 million).
   - Higher compensation to property owners for damages during construction, based on National Energy Board (NEB) compensation settlements recently experienced in Alberta ($4 million).

Risk Analysis - (This section is be filled out only if there is a change to the project risk).

b) Licensing & Environmental Assessment (total contingency = $13 million or 21% of the base costs)
- Greatest risk for licensing is in the costs for aboriginal and community consultations ($9 million).
- Potential for even more extensive environmental monitoring and assessments, based on our experiences with the Wuskwatim project ($4 million).

c) Northern 230kV Collector Lines (total contingency = $10 million or 12 % of the base costs)
Design uncertainty and exact location of the northern converter station could increase the total line lengths assumed.

d) Property for 500kV dc Transmission Line (total contingency = $4 million or 18% of the base costs)
Potential increases in land values, by as much as 50%, based on the NEB compensation settlements recently experienced in Alberta. Note however that this risk estimate does not include any costs for expropriation of land and the associated legal expenses.

CONVERTER-RELATED ITEMS (total contingency of $382 million or 26% of the base costs):

e) Riel Converter Station (total contingency = $200 million or 39% of the base costs)
Based on a Range Estimating session, recommend contingency for equipment costs due to limited number of suppliers worldwide and variability on exchange rates ($100 million for converters and $100 million for synchronous condensers).

f) Northern Converter Station (total contingency = $135 million or 18% of the base costs)
Based on a Range Estimating session, recommend contingency for equipment costs due to limited number of suppliers worldwide and variability on exchange rates ($100 million for converters); and potential for higher costs associated with northern work ($35 million).

g) Riel Site Development for Converters & AC Switchyard (total contingency = $25 million or 19% of the base costs)
Final Design for Phase A of the Riel Switchyard won't be available from the engineer and procure contract until January 2010, while final design for Phase B is three to six years away. There is also uncertainty with line protection, cyber security, and building strength. Re-work is anticipated for site preparation, as construction will be started ahead of final design to protect against the risk of a wet summer delaying the construction progress.

h) Northern 230kV AC Switchyard (total contingency = $15 million or 31% of the base costs)
Based on a Range Estimating session, recommend contingency for potentially higher costs associated with northern work.

i) Construction Power Station for Northern Converter Station (total contingency = $4 million or 27% of the base costs)
Design and construction estimate are based on a conceptual Single Line Diagram (SLD) only; the site size and exact location of the Converter Station is not yet confirmed.

j) Northern and Riel Electrode Lines (total contingency = $3 million or 36% of the base costs)
The length of the lines is not certain, as Electrode sites have not yet been determined. Also provides for the use of steel towers if necessary (base estimate assumes wood).

Risk Analysis - (This section is be filled out only if there is a change to the project risk).

Management Reserve (total of $334 million in base 2009$):

Also identified during the risk assessment but not included in the contingency estimate at this time, are the management reserve items listed below. Though each of the components covered by this list has a contingency amount included within the project estimate, there is potential for further increases above those contingency amounts, for the following factors:

- Premium if basing the converters estimate on pricing received from the most experienced supplier ($102 million, high probability).
- Uncertainty on the northern interconnecting station modifications at Henday Converter Station and Long Spruce Generating Station, as the scope is not well defined at this time ($20 million, high probability).
- Allowance for greater requirement for engineering, project management and construction management on the Northern Converter Station and the Riel Converter Station projects ($14 million, high probability).
- Allowance for poor soil conditions during construction of the Northern Converter Station ($12 million, high probability)
- Market conditions for transmission line construction labour may increase costs by as much as 20% ($70 million, low probability).
- Market conditions for transmission-related materials or commodities (e.g., towers, hardware, conductor, insulators, foundations, communications equipment) may increase by 10-25% ($61 million, low probability).
- Increase to design, supply and install (construction) costs for the Northern 230kV AC Switchyard if a gas-insulated station (GIS) is chosen instead of an air-insulated station (AIS), due to unknown soil conditions ($55 million, low probability).

Some of the schedule-related risks associated with meeting an October 2017 in-service are as follows:

- The detailed route selection must be finalized by December 2010.
- An Environmental Licence must be received by September 2012.
- Certain activities will need to proceed in parallel with the environmental licensing process:
  - acquiring permits to work on crown lands,
  - purchase of some materials and/or purchase of extra towers and foundations types to accommodate unexpected conditions due to lack of geotechnical information,
  - temporary permits for site investigation activities (including field drilling) in order for design of foundations to be finalized and materials ordered for the construction start date.
- Completion of the northern portion of the Western route is based on having five winter seasons for access and construction. The southern portion of the Western route can be built year-round, however it is subject to more property and land access issues.

RESOURCE REQUIREMENTS AND CAPITAL BUDGET ESTIMATE:

Resource Requirements (This section is be filled out only if there is a change to the resource requirements).

No change.

Total Budget - (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Previous CPJ / CPJ Addendum	This CPJ Addendum	Increase (Decrease)
Prev. Actuals	$ 7,613	$ 7,613	$ -
2007/08	$ 1,875	$ 1,955	$ 80
2008/09	$ 2,901	$ 17,878	$ 14,977
2009/10	$ 9,298	$ 33,037	$ 23,739
2010/11	$ 12,994	$ 80,542	$ 67,548
2011/12	$ 25,115	$ 110,970	$ 85,855
2012/13	$ 172,475	$ 271,913	$ 99,438
2013/14	$ 331,532	$ 671,609	$ 340,077
2014/15	$ 420,146	$ 691,071	$ 270,926
2015/16	$ 579,614	$ 823,189	$ 243,576
2016/17	$ 535,141	$ 866,711	$ 331,570
2017/18	$ 145,948	$ 375,335	$ 229,387
2018/19	$ 3,184	$ 1,926	$ (1,258)
Total	$ 2,247,835	$ 3,953,749	$ 1,705,914

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III Western Routed T/L & 2000MW Converters – **TRANSMISSION LINE**

Recommendation (This section is required for all Addendums).

Increase the budget by $177,991,000 for the Transmission Line components of the Bipole III Western Routed Transmission Line & 2000MW Converters complex, to a revised total of $1,259,915,000, in order to incorporate the following:

- review of the base estimate for the property, design and construction of the HVdc transmission line, and of the licensing and environmental assessment for the overall complex (total increase of $152,122,000);
- inclusion of contingency for the above-mentioned components (total increase of $49,353,000); and
- the resultant changes to interest and escalation (decrease of $23,485,000).

Project Scope (This section is be filled out only if there is a change to the scope).

The scope of this portion of the Bipole III complex includes the following major components:

- Design and construction of a western-routed 500kV HVdc transmission line from the Keewatinoow Converter Station to the Riel Converter Station, approximately 1341km in length.
- Licensing and environmental assessment for the overall Bipole III complex (i.e., including the 2000 MW converters and AC collector system).
- Property acquisition and/or easements for the 500kV HVdc transmission line.

Background (This section is be filled out only if there is information relevant to the recommendation).

CPJ Addendum #04, submitted in April 2005, was the first introduction to the Capital Expenditure Forecast of a western-routed 500kV HVdc transmission line with 2000MW of converters. The budget submitted with CPJ Addendum #04 was preliminary only, pending completion of studies by System Planning. It was based on an estimate prepared by Teshmont Consultants in 2001.

CPJ Addendum #05, submitted in May 2007, addressed an increase of 45km to the length of the transmission line, as well as increases being experienced in transmission line material and construction costs due to market prices. The cost estimates for licensing, property and contingency were not updated at that time.

This CPJ Addendum #06a covers a budget increase of $177,991,000 in association with the Transmission Line components of the Bipole III Western Routed Transmission Line & 2000MW Converters complex:

a) <u>500kV HVdc Transmission Line (base increase of $140,714,000):</u>
   - Design change from double to triple conductor, in order to lower the surface field gradient to accepted worldwide practices and thus minimize the likelihood of anomalous flashovers that have been experienced on the existing bipoles in the past 20 years.
   - Incorporation of the Transmission Line Agreement for unionization of construction labour.
   - Application of the revised corporate policy for compensation for private property.

b) <u>Licensing & Environmental Assessment for the Bipole III complex (base increase of $4,912,000):</u>
   - More comprehensive aboriginal and community consultations.
   - Additional studies related to converter size.

Background (This section is be filled out only if there is information relevant to the recommendation).
c) Property Acquisition and/or Easements for the Transmission Line (base increase of $6,497,000): ▪ More privately-owned land associated with the western route. d) The revised budget also includes contingency at $49,353,000 (Project Risk Analysis section contains details). The above changes to the base estimate and contingency, and a change in base dollars from 2007 to 2010, result in a net decrease of $23,485,000 to forecasted escalation and interest.

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals (This section is required for all Addendums).
A third 500kV HVdc transmission line with converter stations rated for 2000MW will provide for increased reliability to the Manitoba Hydro system, due to the critical risk to the Province and the Corporation of a Dorsey Converter Station outage or an Interlake (Bipole I and II) corridor outage. It will also provide an increase in southern power due to reduced line losses on the existing Bipoles I and II (approximately 76MW in normal steady state operation prior to the addition of new generation into the northern collector system).

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis		
Discount Rate	%	For current corporate rates see G911

Recommended Option	**NPV Benefits (Costs)**
No change.	

Other Alternatives Considered	**NPV Benefits (Costs)**

Project Risk Analysis - (This section is be filled out only if there is a change to the project risk).
A total of $49,353,000 of contingency (approximately 6% of the base estimate) is included in the budget amount for CPJ Addendum #06a, to cover the following: a) 500kV HVdc Transmission Line (contingency of $39,967,000 or 5% of the base estimate): Potential changes to the detailed route selection or line length. b) Licensing & Environmental Assessment (contingency of $9,386,000 or 15% of the base estimate): Potential for greater requirements for aboriginal and community consultations, and for more extensive environmental monitoring and assessments during construction.

Project Risk Analysis - (This section is be filled out only if there is a change to the project risk).

The following risks create a potential for additional costs:
- Market conditions for transmission line construction labour, materials or commodities.
- Unforeseen geotechnical conditions.
- Further changes to corporate policy for private property compensation.

Some of the schedule-related risks associated with meeting an October 2017 in-service are as follows:
- Environmental License to be received by September 2012.
- Certain activities will need to proceed in parallel with the environmental licensing process:
  - acquiring permits to work on crown lands,
  - purchase of some materials and/or purchase of extra towers and foundations types to accommodate unexpected conditions due to lack of geotechnical information,
  - temporary permits for site investigation activities (including field drilling) in order for design of foundations to be finalized and materials ordered for the construction start date.
- Completion of the northern portion of the line is based on having five winter seasons for access and construction.

Capital Budget Estimate - (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Previous CPJ / CPJ Addendum	This CPJ Addendum	Increase (Decrease)
Prev. Actuals	$ 17,207	$ 24,613	$ 7,406
2010/11	$ 5,801	$ 16,118	$ 10,317
2011/12	$ 10,235	$ 24,830	$ 14,595
2012/13	$ 146,630	$ 59,866	$ (86,764)
2013/14	$ 181,825	$ 162,043	$ (19,782)
2014/15	$ 201,556	$ 298,935	$ 97,379
2015/16	$ 216,344	$ 318,454	$ 102,110
2016/17	$ 227,477	$ 234,575	$ 7,098
2017/18	$ 71,665	$ 120,055	$ 48,390
2018/19	$ 3,184	$ 426	$ (2,758)
2019/20	$ -	$ -	$ -
Total	$ 1,081,923	$ 1,259,915	$ 177,991

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III Western Routed T/L & 2000MW Converters – **CONVERTER STATIONS**

Recommendation (This section is required for all Addendums).

Increase the budget by $724,335,000 for the Riel and Keewatinoow Converter Station components of the Bipole III Western Routed Transmission Line & 2000MW Converters complex, to a revised total of $1,828,532,000, in order to incorporate the following:

- review of the base estimate for the property, design and construction of the Riel and Keewatinoow Converter Stations and 230kV Switchyards (total increase of $474,226,000);
- inclusion of contingency for the above-mentioned components (total increase of $138,926,000); and
- the resultant changes to interest and escalation (increase of $111,183,000).

Project Scope (This section is be filled out only if there is a change to the scope).

The scope of this portion of the Bipole III complex includes the following major components:

- Design and construction of the 2000 MW Riel Converter Station and 230kV AC Switchyard.
- Design and construction of the 2000 MW Keewatinoow Converter Station and 230kV AC Switchyard.
- Property acquisition and/or easements for the Riel and Keewatinoow Converter Stations.

The proposed budget assumes use of voltage source converters for both the Riel and Keewatinoow Converter Stations without synchronous condensers at the Riel Converter Station.

Background (This section is be filled out only if there is information relevant to the recommendation).

CPJ Addendum #04, submitted in April 2005, was the first introduction to the Capital Expenditure Forecast of a western-routed 500kV HVdc transmission line with 2000MW of converters. The budget submitted with CPJ Addendum #04 was preliminary only, pending completion of studies by System Planning. It was based on an estimate prepared by Teshmont Consultants in 2001.

CPJ Addendum #05, submitted in May 2007, did not include re-estimates for the converter stations, nor was contingency included for the converter stations, as these components had not yet been reviewed in detail.

This CPJ Addendum #06b covers a budget increase of $724,335,000 in association with the Riel and Keewatinoow Converter Station components of the Bipole III Western Routed Transmission Line & 2000MW Converters complex:

a) <u>Riel Converter Station and 230kV AC Switchyard (base increase of $169,355,000):</u>
   - Converter and HVdc equipment costs have remained relatively unchanged when comparing 2009 mini-spec pricing versus the escalated 2001 estimate figures; however, there were no explicit indirect costs in the 2001 estimate and no interfacing costs.

b) <u>Keewatinoow Converter Station and 230kV AC Switchyard (base increase of $286,069,000):</u>
   - Converter and HVdc equipment costs have remained relatively unchanged when comparing 2009 mini-spec pricing versus the escalated 2001 estimate figures; however, there were no explicit indirect costs in the 2001 estimate and no interfacing costs.

Background (This section is be filled out only if there is information relevant to the recommendation).
▪ Site development costs have increased for the following reasons: the previous budget assumed that the Conawapa Generating Station infrastructure would be built ahead of Bipole III and therefore costs associated with a construction camp and work areas would be covered by that project's budget; mechanical services such as fire, water, sewer and oil containment, along with security and environmental requirements, were not considered in the 2001 estimate; the site size has increased and soil conditions are worse than identified in the 2001 estimate; the transformer change-out method and the emergency response buildings were not included in the 2001 estimate. c) Property Acquisition and/or Easements for the Converter Stations (base increase of $18,802,000): Property costs for Riel and Keewatinoow Converter Stations were not included in the 2001 estimate. Costs for the Riel site are more substantial than the Keewatinoow site, and include $6.4 million for station site properties, and $12.3 million for buffer properties that have been purchased from private owners. In addition to the above, the revised budget also includes the introduction of contingency at $138,926,000 (Project Risk Analysis section contains details). The changes to the base estimate and inclusion of contingency, along with the change in base dollars from 2007 to 2010, result in an increase of $111,183,000 to forecasted escalation and interest.

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals (This section is required for all Addendums).
A third 500kV HVdc transmission line with converter stations rated for 2000MW will provide for increased reliability to the Manitoba Hydro system, due to the critical risk to the Province and the Corporation of aDorsey Converter Station outage or an Interlake (Bipole I and II) corridor outage. It will also provide an increase in southern power due to reduced line losses on the existing Bipoles I and II (approximately 76MW in normal steady state operation prior to the addition of new generation into the northern collector system).

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis		
Discount Rate	%	**For current corporate rates see G911**

Recommended Option	**NPV Benefits (Costs)**
No change.	

Other Alternatives Considered	**NPV Benefits (Costs)**

Project Risk Analysis - (This section is be filled out only if there is a change to the project risk).

A total of $138,926,000 of contingency (approximately 11% of the base estimate) is included in the budget amount for CPJ Addendum #06b, to cover the following:

a) Keewatinoow Converter Station and 230kV AC Switchyard (contingency of $71,960,000 or 12% of the base estimate):
   - Potential changes to equipment costs due to a limited number of suppliers worldwide and variability of exchange rates until contracts are signed.
   - Potentially higher costs due to northern work conditions.

b) Riel Converter Station and 230kV AC Switchyard (contingency of $66,966,000 or 11% of the base estimate):
   - Potential changes to equipment costs due to limited number of suppliers worldwide and variability of exchange rates until contracts are signed.
   - Uncertainty with protection, cyber security and building strength (physical security).

The following risks create a potential for additional costs:
- Potential for greater requirement for engineering, project management and construction management.
- Potential for poor site conditions during construction.
- The potential requirement for synchronous condensers at the Riel Converter Station.

The assumed use of new technology in the form of voltage source converters at both the Keewatinoow and Riel Converter Stations represents an additional risk factor. Confirmation or otherwise of the feasibility of this technology is expected by late 2011.

Capital Budget Estimate - (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Previous CPJ / CPJ Addendum	This CPJ Addendum	Increase (Decrease)
Prev. Actuals	$ 4,243	$ 30,423	$ 26,181
2010/11	$ 6,812	$ 46,255	$ 39,443
2011/12	$ 14,092	$ 59,696	$ 45,604
2012/13	$ 24,477	$ 148,883	$ 124,406
2013/14	$ 141,783	$ 300,258	$ 158,475
2014/15	$ 207,019	$ 290,185	$ 83,166
2015/16	$ 344,041	$ 294,281	$ (49,759)
2016/17	$ 291,378	$ 308,460	$ 17,082
2017/18	$ 70,351	$ 347,692	$ 277,341
2018/19	$ -	$ 2,398	$ 2,398
2019/20	$ -	$ -	$ -
Total	$ 1,104,197	$ 1,828,532	$ 724,335

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III Western Routed T/L & 2000MW Converters – **COLLECTOR LINES**

Recommendation (This section is required for all Addendums).

Increase the budget by $129,722,000 for the Collector Lines components of the Bipole III Western Routed Transmission Line & 2000MW Converters complex, to a revised total of $191,438,000, in order to incorporate the following:

- review of the base estimate for the property, design and construction of the 230kV collector lines for the Keewatinoow Converter Station, the construction power for the Keewatinoow Converter Station, the sectionalization of 230kV transmission line R49R at the Riel Converter Station, and the electrode lines for the Riel and Keewatinoow Converter Stations (total increase of $73,222,000);
- inclusion of contingency for the above-mentioned components (total increase of $17,203,000); and
- the resultant changes to interest and escalation (increase of $39,297,000).

Project Scope (This section is be filled out only if there is a change to the scope).

The scope of this portion of the Bipole III complex includes the following major components:

- Design and construction of three permanent and two temporary 230kV collector lines for the Keewatinoow Converter Station.
- Construction power substation for the Keewatinoow Converter Station.
- Design and construction for the Riel and Keewatinoow electrode lines.
- Sectionalization of 230kV transmission line R49R at Riel.
- Property acquisition and/or easements for the collector and electrode lines.

Background (This section is be filled out only if there is information relevant to the recommendation).

CPJ Addendum #04, submitted in April 2005, was the first introduction to the Capital Expenditure Forecast of a western-routed 500kV HVdc transmission line with 2000MW of converters. The budget submitted with CPJ Addendum #04 was preliminary only, pending completion of studies by System Planning. It was based on an estimate prepared by Teshmont Consultants in 2001.

CPJ Addendum #05, submitted in May 2007, did not include re-estimates for the northern collector lines, the two electrode lines, the related property, or contingency.

This CPJ Addendum #06c covers a budget increase of $129,722,000 in association with the Collector Lines components of the Bipole III Western Routed Transmission Line & 2000MW Converters complex:

a) <u>Keewatinoow 230kV Collector Lines (base increase of $35,756,000):</u>
The 2001 estimate included only three collector lines, while this estimate has two more (temporary) collector lines. The two temporary lines are required in lieu of an earlier introduction of additional generation in the northern collector system. At the time of the 2001 estimate, the planned in-service for the Conawapa Generating Station (GS) was only two years after Bipole III. Now that the in-service for Conawapa GS is planned for several years later, two temporary lines are required in order to permit full use of a 2000MW rating for Bipole III in the event of a Dorsey Station or Bipole I / II outage.

In addition, the cost of transmission line material and construction has increased since 2001.

Background (This section is be filled out only if there is information relevant to the recommendation).

b) Keewatinoow Construction Power (base increase of $23,381,000):
The 2001 estimate did not include the requirement for a construction power substation, as it was assumed it would have already been built for construction of the Conawapa GS. With the change in the sequence, the Bipole III project will now be the first development to require this construction power substation.

c) Property Acquisition and/or Easements for the Collector and Electrode Lines (base increase of $10,732,000):
The 2001 estimate did not include any property costs for the Keewatinoow collector lines or the Riel and Keewatinoow electrode lines.

d) Sectionalization of 230kV Transmission Line R49R at Riel (base increase of $1,955,000):
This had been included in the Riel Sectionalization project but was deferred to coincide with the Bipole III converters. It is required to accommodate and reliably transmit a 2000MW Bipole III at Riel.

e) Riel and Keewatinoow Electrode Lines (base increase of $1,398,000):
The cost of line material and construction has increased since 2001.

f) The revised budget also includes contingency at $17,203,000 (Project Risk Analysis section contains details).

The above changes to the base estimate and contingency, and a change in base dollars from 2007 to 2010, result in an increase of $39,297,000 to forecasted escalation and interest.

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals (This section is required for all Addendums).

A third 500kV HVdc transmission line with converter stations rated for 2000MW will provide for increased reliability to the Manitoba Hydro system, due to the critical risk to the Province and the Corporation of a Dorsey Converter Station outage or an Interlake (Bipole I and II) corridor outage. It will also provide an increase in southern power due to reduced line losses on the existing Bipoles I and II (approximately 76MW in normal steady state operation prior to the addition of new generation into the northern collector system).

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis		
Discount Rate	%	For current corporate rates see G911

Recommended Option	NPV Benefits (Costs)
No change.	

Other Alternatives Considered	NPV Benefits (Costs)

Project Risk Analysis - (This section is be filled out only if there is a change to the project risk).

A total of $17,203,000 of contingency (approximately 15% of the base estimate) is included in the budget amount for CPJ Addendum #06c, to cover the following:

a) Keewatinoow Collector Lines (contingency of $8,952,000 or 13% of the base estimate):
Provides for potentially higher costs for material and construction labour.

b) Keewatinoow Construction Power (contingency of $5,451,000 or 23% of the base estimate):
Estimates are based on a conceptual Single Line Diagram only. The site size and exact location are not yet finalized. Backup power requirements are currently under review.

c) Riel and Keewatinoow Electrode Lines (contingency of $2,800,000 or 34% of the base estimate):
Line lengths are uncertain, as the Electrode sites for Riel and Keewatinoow have not been finalized. Also provides for use of steel towers if necessary for reliability.

The following risks create a potential for additional costs:
- Potential for poor site conditions during construction.
- Potentially higher costs due to northern work conditions.
- Further changes to corporate policy for private property compensation.

Capital Budget Estimate - (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Previous CPJ / CPJ Addendum	This CPJ Addendum	Increase (Decrease)
Prev. Actuals	$ 237	$ 0	$ (237)
2010/11	$ 381	$ 2,121	$ 1,740
2011/12	$ 788	$ 19,917	$ 19,130
2012/13	$ 1,368	$ 52,709	$ 51,341
2013/14	$ 7,924	$ 30,141	$ 22,217
2014/15	$ 11,571	$ 30,927	$ 19,357
2015/16	$ 19,229	$ 34,255	$ 15,026
2016/17	$ 16,286	$ 13,549	$ (2,737)
2017/18	$ 3,932	$ 7,818	$ 3,886
2018/19	$ -	$ -	$ -
2019/20	$ -	$ -	$ -
Total	$ 61,715	$ 191,438	$ 129,722

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION

Project Name

Bipole III Community Development Initiative – **TRANSMISSION LINE**

Recommendation

Establish budget to incorporate Bipole III Community Development Initiative ("CDI") that was approved by the Manitoba Hydro-Electric Board in May 2010.

Project Scope

Estimate based on the net present value of a 10-year program valued at up to $6 million per year.

Background

The Manitoba Hydro-Electric Board approved the establishment of a Bipole III Community Development Initiative ("CDI"), valued at up to $6 million a year, for Manitoba Hydro to provide benefits to communities in the vicinity of the Bipole III project facilities (May 20, 2010, minute 808-10-03). Following this approval, the Bipole III Preliminary Preferred Route became known and was released publicly in July 2010. From the time of Board approval, a multi-business unit CDI Working Group continued to meet to refine the CDI approach, in light of the preliminary preferred route, and to develop related communications material. Following feedback regarding the CDI, there was consensus that the refinements described in the recommendation be implemented, which include the following:

a) That CDI payments be provided for a 10 year period, with the possibility of program renewal at the end of the 10 year period;
b) That CDI payments begin upon receipt of the Bipole III regulatory approvals;
c) That the boundary for communities whose eligibility is based on proximity to the line be limited to 40 km;
d) That the eligibility requirements for incorporated towns and villages be such that a town or village must be located within a municipality traversed by the line and be located within 40 km of the line; and
e) That the CDI payments to communities be adjusted annually with the change in inflation.

The requested budget increase is planned as a 2013/14 expense based on all regulatory approvals being received no later than December 2013.

JUSTIFICATION—BUSINESS CASE ANALYSIS (SUMMARY):

Justification and Link to Corporate/Business Unit Goals

The CDI program remains inclusive of a variety of interests; is strongly linked to the Bipole III facilities; and will be an effective means of promoting community support for hosting the Bipole III project facilities.

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III Project – **TRANSMISSION LINE**

Recommendation (This section is required for all Addendums).

Increase the budget by $395 million for the Transmission Line components of the Bipole III Project, to a revised total of $1,655 million and a revised in-service date of July, 2018.

Project Scope (This section is be filled out only if there is a change to the scope).

The scope of this portion of the Bipole III Project includes the following major components:
- Design and construction of a western-routed 500kV HVdc transmission line from the Keewatinohk (Keewatinoow) Converter Station to the Riel Converter Station.
- Property acquisition and/or easements for the 500kV HVdc transmission line.
- Design and construction of the Bipole III Communications transport system.
- Licensing and environmental assessment for the overall Bipole III complex (i.e., including the 2000 MW converters and AC collector system).

Changes to scope include: revised line length of final approved route, issued Licence & Conditions, revised landowner compensation strategy and policy, increased Bipole III rating to 2300 MW, and revised project in-service date of July 2018.

Background (This section is be filled out only if there is information relevant to the recommendation).

The last project re-estimate was completed in 2010, based on a preferred routing of the line prior to issuance of the Project Licence.

The revised estimate incorporates a more detailed scope based on an issued environment act licence, approved finalized route and right-of-way width, as well as up-to-date market information. Also since the last estimate, the project licence and permits were received later than planned, resulting in 1.5 lost winter seasons of 5 total planned. The estimate is based on the need for at least 4 more winter seasons to construct the transmission line and change to project in-service of July 2018.

The recommended budget is based on a P50 estimate that includes all base costs and contingency at a 50% confidence level and management reserves for market uncertainty risk for transmission line construction work.

P50 Estimate:

Since the last estimate was developed in 2010 it was necessary to bring the estimate to 2014$ and several items in the point estimate had to be adjusted to match the increased level of detail that has been identified within the current scope. This resulted in an increase of $363 million to the P50 Estimate as a result of the following:

- Incorporation of Environment Act Licence conditions and monitoring requirements
- Changes to the finalized route (increased length, additional towers and increased right-of-way width)
- Updated land acquisition costs
- Recommended contingency of [redacted] (increase of $61M) to address remaining uncertainty. See

Background (This section is be filled out only if there is information relevant to the recommendation).

Risk Analysis section.

Reserves:
A Management Reserve has been established to address significant risks related to bidding market and pricing uncertainty for Transmission Line construction work (increase of $100M). See Risk Analysis section.

In-Service Costs:
The overall increase to the in-service cost of the project is $395M (31%). This increase to the in-service cost is due to the increases in the P50 base estimate, the change to the project in-service date, and addition of the Management Reserve. These increases are offset by reduced interest and escalation costs.

Justification (This section is required for all addendums).

A third 500kV HVdc transmission line with converter stations will provide for increased reliability to the Manitoba Hydro system, due to the critical risk to the Province and the Corporation of a Dorsey Converter Station outage or an Interlake (Bipole I and II) corridor outage. It will also provide an increase in southern power due to reduced line losses on the existing Bipoles I and II (approximately 76MW in normal steady state operation prior to the addition of new generation into the northern collector system).

The rating for Bipole III was increased from 2000MW to 2300MW to ensure adequate spare HVdc transmission on the northern collector system. The increased rating ensures future generation associated with Keeyask and Conawapa can be transmitted via Bipole I, Bipole II and Bipole III in the event of a single valve group outage. The increased rating limits the amount of future upgrades and equipment replacement needed on the Bipole III HVdc system to accommodate future Conawapa generation.

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis		
Discount Rate	**% For current corporate rates see G911**	**For clarification on hurdle rates, contact Economic Analysis Department**

Recommended Option	NPV Benefits/(Costs)
No change.	

Other Alternatives Considered	NPV Benefits/(Costs)
N/A.	

Risk Analysis – (This section is be filled out only if there is a change to the project risk).

The risk & contingency methodology outlined at the NFAT for Keeyask & Conawapa Projects has been applied to the revised Bipole III Project estimate. The estimate includes a recommended project contingency at a P50 confidence level to address remaining areas of uncertainty.

Risk Analysis – (This section is be filled out only if there is a change to the project risk).

Additionally, this portion of the Bipole III Project includes a recommended Management Reserve of \$100M associated with bidding market and pricing uncertainty for Transmission Line construction work. This remains the greatest area of uncertainty for Bipole III and the potential cost variation associated with this risk is best addressed through the inclusion of Management Reserve funds.

An additional, significant area of uncertainty is the potential impacts to schedule due to further delays in acquisition of private lands. A Management Reserve for this risk has not been recommended as part of the project budget. However, there will be cost impacts to the project should the risk occur.

Total Budget – (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Prev. Approved CPJ/Addendum	Proposed CPJ Addendum	Increase (Decrease)
Prev. Actuals	$ 24,613	$ 24,613	$ -
2010/11	$ 16,118	$ 19,002	$ 2,884
2011/12	$ 24,830	$ 18,350	$ (6,480)
2012/13	$ 59,866	$ 25,091	$ (34,775)
2013/14	$ 162,043	$ 54,276	$ (107,767)
2014/15	$ 298,935	$ 203,458	$ (95,477)
2015/16	$ 318,454	$ 360,455	$ 42,001
2016/17	$ 234,575	$ 381,047	$ 146,472
2017/18	$ 120,055	$ 493,821	$ 373,766
2018/19	$ 426	$ 75,257	$ 74,831
Total	$ 1,259,915	$ 1,655,371	$ 395,456

Proposed Schedule (This section is be filled out only if there is a change to the project schedule).

The schedule has been updated for the proposed change to in-service date of July 2018.

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III Project – **CONVERTER STATIONS**

Recommendation (This section is required for all Addendums).

Increase the budget by $ 846.5 million for the Converter Station components of the Bipole Project, to a revised total of $2,675 and a revised in-service date of July, 2018.

Project Scope (This section is be filled out only if there is a change to the scope).

The scope of this portion of the Bipole III complex includes the following major components:
- Design and construction 2300 MW Riel Converter Station and 230 kV AC Switchyard.
- Design and construction 2300 MW Keewatinohk (Keewatinoow) Converter Station and 230 kV AC Switchyard.
- Property acquisition and/or easements for the Riel and Keewatinohk Converter Stations.

Changes to scope include: Selection of LCC HVdc technology requiring the inclusion of Synchronous Condensers, increased Bipole III rating to 2300 MW, and revised project in-service date of July 2018.

Background (This section is be filled out only if there is information relevant to the recommendation).

The last project re-estimate was completed in 2010, based largely on historical and budgetary pricing from vendors as well as an assumption of VSC technology for the HVdc Converter and therefore no requirement for synchronous condensers.

The revised estimate is based on LCC HVdc technology as this was the technology bid by all vendors and incorporates the bid pricing received. The selection of LCC technology has resulted in synchronous condensers being included in the revised estimate. Additionally, the awarded contract prices for the Keewatinohk Camp, Keewatinohk Site Development and the Keewatinohk 230kV AC Switchyard have been incorporated into the revised estimate. The estimate is based on a project in-service of July 2018, which is required to complete the HVdc Converters installation.

The recommended budget is based on a P50 estimate that includes all base costs and contingency at a 50% confidence level.

P50 Estimate:

Since the last estimate was developed in 2010 it was necessary to bring the estimate to 2014$ and several items in the point estimate had to be adjusted to match the increased level of detail that has been identified within the current scope. This resulted in an increase of $649 million to the P50 Estimate as a result of the following:

- Incorporation of contract costs for the Keewatinohk 230kV AC Switchyard, Keewatinohk Site Development, Keewatinohk Camp and Keewatinohk Camp Services
- Incorporation of bid price for the Keewatinohk and Riel HVdc Converter Equipment contract
- Inclusion of Synchronous Condensers in the scope of work as a result of LCC technology for the HVdc equipment
- Incorporation of allocated portion of actual costs for Riel Sectionalization project
- Incorporation of updated costs for the Riel 230kV AC Switchyard Expansion

Background (This section is be filled out only if there is information relevant to the recommendation).

- Recommended contingency of [redacted] (decrease of $16M) to address remaining uncertainty.

Reserves:
No Management Reserve for the Converter Stations component of the project is recommended to include in the estimate at this time.

In-Service Costs:
The overall increase to the in-service cost of the project is $846.5 (46%). This increase to the in-service cost is due to the increases in the P50 base estimate, the change to the project in-service date, and addition of the Management Reserve. These increases are offset by reduced interest and escalation costs.

Justification (This section is required for all addendums).

A third 500kV HVdc transmission line with converter stations will provide for increased reliability to the Manitoba Hydro system, due to the critical risk to the Province and the Corporation of a Dorsey Converter Station outage or an Interlake (Bipole I and II) corridor outage. It will also provide an increase in southern power due to reduced line losses on the existing Bipoles I and II (approximately 76MW in normal steady state operation prior to the addition of new generation into the northern collector system).

The rating for Bipole III was increased from 2000MW to 2300MW to ensure adequate spare HVdc transmission on the northern collector system. The increased rating ensures future generation associated with Keeyask and Conawapa can be transmitted via Bipole I, Bipole II and Bipole III in the event of a single valve group outage. The increased rating limits the amount of future upgrades and equipment replacement needed on the Bipole III HVdc system to accommodate future Conawapa generation.

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis		
Discount Rate	% For current corporate rates see G911	For clarification on hurdle rates, contact Economic Analysis Department

Recommended Option	**NPV Benefits/(Costs)**
No change.	

Other Alternatives Considered	**NPV Benefits/(Costs)**

Risk Analysis – (This section is be filled out only if there is a change to the project risk).

The risk & contingency methodology outlined at the NFAT for Keeyask & Conawapa Projects has been applied to the revised Bipole III Project estimate. The estimate includes a recommended project contingency at a P50 confidence level to address remaining areas of uncertainty.

Inclusion of a Management Reserve for this portion of the Bipole III complex is not considered necessary

Risk Analysis – (This section is be filled out only if there is a change to the project risk).

at this time.

Total Budget – (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Prev. Approved CPJ/Addendum	Proposed CPJ Addendum	Increase (Decrease)
Prev. Actuals	$ 30,423	$ 30,423	$ -
2010/11	$ 46,255	$ 28,069	$ (18,186)
2011/12	$ 59,696	$ 36,417	$ (23,279)
2012/13	$ 148,883	$ 79,718	$ (69,165)

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III Project – **COLLECTOR LINES**

Recommendation (This section is required for all Addendums).

Increase the budget by $68.7 million for the Collector Lines components of the Bipole III Project, to a revised total of $260.2 million and a revised in-service date of July, 2018.

Project Scope (This section is be filled out only if there is a change to the scope).

The scope of this portion of the Bipole III Project includes the following major components:
- Design and construction of three permanent and two temporary 230 KV collector lines for the Keewatinohk (Keewatinoow) Converter Station.
- Construction power substation, 138 KV line, microwave tower, and distribution feeders for the Keewatinohk Converter Station.
- Design and construction of the Riel and Keewatinohk electrode lines.
- Sectionalization of 230 KV transmission line R49R at Riel and associated modifications at Ridgeway and Rosser stations.
- Property acquisition and/or easements for the above components.
- Design and construction of a new bay and modifications at existing Long Spruce 230 KV AC switchyard for the new collector line to Keewatinohk Converter Station.
- Design and construction of a new bay and modifications at existing Henday 230 KV AC switchyard for the four new collector lines to Keewatinoow Converter Station.
- Design and construction of breaker replacements at existing stations (Ridgeway, Rosser, and McPhillips) for Bipole III.

Changes to scope include: the issued Licence & Conditions, double circuit requirement for one collector line, increased reliability design for electrode lines, updated assumptions for direct negotiated clearing and construction contracts, inclusion of Long Spruce and Henday 230 KV station expansions/modifications, inclusion of breaker replacements, and revised schedule and project in-service date to July 2018.

Background (This section is be filled out only if there is information relevant to the recommendation).

The last project re-estimate was completed in 2009/10, based on conceptual scope of collector line components, prior to issuance of the Project Licence.

The revised estimate incorporates a more detailed scope based on an issued environment act licence, increased scope (new items in this component), as well as up-to-date market information. The estimate is based on a project in-service of July 2018, which is required to complete the HVdc Converters installation.

The recommended budget is based on a P50 estimate that includes all base costs and contingency at a 50% confidence level.

<u>P50 Estimate:</u>

Since the last estimate was developed in 2010 it was necessary to bring the estimate to 2014$ and several items in the point estimate had to be adjusted to match the increased level of detail that has been identified within the current scope. In addition, new items were included in the current scope for this component.

Background (This section is be filled out only if there is information relevant to the recommendation).

This resulted in an increase of $83 million to the P50 Estimate as a result of the following:

- Incorporation of Environment Act Licence conditions and monitoring requirements
- Change to include a double circuit requirement for the Keewatinoow to Long Spruce AC collector line
- Incorporation of increased reliability design for both electrode lines
- Change to assume Clearing, 230kV AC transmission line construction and Construction Power contracts as Direct Negotiated Contracts (DNCs)
- Inclusion of new items – Long Spruce and Henday 230 KV station expansions/modifications and breaker replacements projects
- Recommended contingency of [redacted] (increase of $800K) for this component, to address remaining uncertainty. See Risk Analysis section.

<u>Reserves:</u>
No Management Reserve for the Collector Lines components is recommended to include in the estimate at this time. See Risk Analysis section.

<u>In-Service Costs:</u>
The overall increase to the in-service cost of the project for this component is $68 M (36%). This increase to the in-service cost is due to the increases in the P50 base estimate, the change to the project in-service date and increase in the recommended contingency. These increases are offset by reduced interest and escalation costs.

Justification (This section is required for all addendums).

A third 500kV HVdc transmission line with converter stations will provide for increased reliability to the Manitoba Hydro system, due to the critical risk to the Province and the Corporation of a Dorsey Converter Station outage or an Interlake (Bipole I and II) corridor outage. It will also provide an increase in southern power due to reduced line losses on the existing Bipoles I and II (approximately 76MW in normal steady state operation prior to the addition of new generation into the northern collector system).

The rating for Bipole III was increased from 2000MW to 2300MW to ensure adequate spare HVdc transmission on the northern collector system. The increased rating ensures future generation associated with Keeyask and Conawapa can be transmitted via Bipole I, Bipole II and Bipole III in the event of a single valve group outage. The increased rating limits the amount of future upgrades and equipment replacement needed on the Bipole III HVdc system to accommodate future Conawapa generation.

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis		
Discount Rate	% For current corporate rates see G911	For clarification on hurdle rates, contact Economic Analysis Department

Recommended Option	**NPV Benefits/(Costs)**
No change.	

Other Alternatives Considered	NPV Benefits/(Costs)
N/A	

Risk Analysis – (This section is be filled out only if there is a change to the project risk).

The risk & contingency methodology outlined at the NFAT for Keeyask & Conawapa Projects has been applied to the revised Bipole III Project estimate. The estimate includes a recommended project contingency at a P50 confidence level to address remaining areas of uncertainty.

Inclusion of a Management Reserve for this portion of the Bipole III complex is not considered necessary at this time.

Total Budget – (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Prev. Approved CPJ/Addendum	Proposed CPJ Addendum	Increase (Decrease)
Prev. Actuals	$ 0	$ 0	$ -
2010/11	$ 2,121	$ 386	$ (1,735)
2011/12	$ 19,917	$ 2,075	$ (17,842)
2012/13	$ 52,709	$ 4,394	$ (48,315)
2013/14	$ 30,141	$ 26,265	$ (3,876)
2014/15	$ 30,927	$ 58,432	$ 27,505
2015/16	$ 34,255	$ 75,516	$ 41,261

ADDENDUM NUMBER	**DATE** (yyyy mm dd)	**REVISION**	**REVISED BY**	**APPROVED BY**

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).
Bipole III Project – **COMMUNITY DEVELOPMENT INITIATIVE (CDI)**

Recommendation (This section is required for all Addendums).
Increase the budget by $1.2 million for the Bipole III Community Development Initiative ("CDI") fund, that was approved by the Manitoba Hydro-Electric Board in May 2010, to a revised total of $62.0 million

Project Scope (This section is be filled out only if there is a change to the scope).
Community Development Initiative ("CDI") fund for Manitoba Hydro to provide benefits to communities in vicinity of the Bipole III Project

Background (This section is be filled out only if there is information relevant to the recommendation).

The Manitoba Hydro-Electric Board approved the establishment of a Bipole III Community Development Initiative ("CDI"), valued at up to $6 million a year, for Manitoba Hydro to provide benefits to communities in the vicinity of the Bipole III project facilities (May 20, 2010, minute 808-10-03).

Following this approval, the Bipole III Preliminary Preferred Route became known and was released publicly in July 2010. From the time of Board approval, a multi-business unit CDI Working Group continued to meet to refine the CDI approach, in light of the preliminary preferred route, and to develop related communications material. Following feedback regarding the CDI, there was consensus that the refinements described in the recommendation be implemented, which include the following:

a) That CDI payments be provided for a 10 year period, with the possibility of program renewal at the end of the 10 year period;
b) That CDI payments begin upon receipt of the Bipole III regulatory approvals;
c) That the boundary for communities whose eligibility is based on proximity to the line be limited to 40 km;
d) That the eligibility requirements for incorporated towns and villages be such that a town or village must be located within a municipality traversed by the line and be located within 40 km of the line; and
e) That the CDI payments to communities be adjusted annually with the change in inflation.

Justification (This section is required for all addendums).
The CDI program remains inclusive of a variety of interests; is required as part of Bipole III; and will be an effective means of promoting community support for hosting the Bipole III project facilities

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

ADDENDUM NUMBER	**DATE** (yyyy mm dd)	**REVISION**	**REVISED BY**	**APPROVED BY**

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III Project – **TRANSMISSION LINE**

Recommendation (This section is required for all Addendums).

Total net in-service cost has increased by $302.245 million, from $1,655.371 million to $1,957.616 million from the last approved CPJ addendum, with the in-service date to remain at July, 2018.

Project Scope (This section is be filled out only if there is a change to the scope).

The scope for this portion of the Bipole III complex includes the following major components:

- Design and construction of a western-routed 500kV HVdc transmission line from the Keewatinohk Converter Station to the Riel Converter Station.
- Property acquisition and/or easements for the 500kV HVdc transmission line.
- Design and construction of the Bipole III Communications transport system.
- Licensing and environmental assessment for the overall Bipole III complex (i.e. including the Converter Stations and AC Collector system).
- Contingency for this Transmission Line project.

Changes to scope: awarded contracts and compressed schedule, CEC prescribed route finalization, additional tower steel suppliers, biosecurity measures implementation in the south and some helicopter tower erection for a portion of the line.

Background (This section is be filled out only if there is information relevant to the recommendation).

The previous project re-estimate was completed in 2014 and was based on a P50 confidence level. The recommended budget is based on a P80 estimate for the Transmission Line, that includes all base costs and contingency at an 80% confidence level.

The revised estimate incorporates actual costs to date as well as awarded contracts and reflects current market conditions. The estimate is based on maintaining a project in-service date of July 2018. The resultant revised P80 point estimate of $1,751 million from $1,400 million (an increase of $350 million relative to the current approved budget) is a result of the following changes:

- Incorporation of actual construction costs and awarded values as a result of higher market rates for anchor and foundations as well as tower assembly erection and stringing contracts than planned; incorporated delay claims (weather and material) experienced to date, construction schedule compression; and increased equipment and vehicles to support construction.
- Incorporation of additional materials required for CEC prescribed southern route changes, delays in materials, premiums to accelerate materials and associated engineering.
- Incorporation of property costs for CEC prescribed southern route, inclusion of LVAC (Land Valuation Appraisal Council) certification and legal fees.
- Incorporation of greater material management costs, project management and construction management.
- Inclusion of greater than planned costs for indigenous relationships management and agreements, as well as actual licensing costs and required project environmental monitoring as a result of the licence conditions.

Background (This section is be filled out only if there is information relevant to the recommendation).
• Recommended [redacted] contingency for remaining risks and schedule acceleration (as the previously approved $210 M , of which included $100 management reserve, has been allocated and spent for the above increases in point estimate; remaining risks are detailed in the Risk Analysis portion of this CPJ addendum). <u>In-Service Costs:</u> The overall increase to the in-service cost of the project is $302 million (18%), from $1,655.4 million to $1,957.6 million. This increase to the in-service cost is due to the increases in the P80 base estimate as noted above ($350 million). These increases are offset by reduced interest and escalation costs ($48 million reduction).

Justification (This section is required for all addendums).
A third 500kV HVdc transmission line with converter stations will provide for increased reliability to the Manitoba Hydro system, due to the critical risk to the Province and the Corporation of a Dorsey Converter Station outage or an Interlake (Bipole I and II) corridor outage. It will also provide an increase in southern power due to reduced line losses on the existing Bipoles I and II (approximately 76MW in normal steady state operation prior to the addition of new generation into the northern collector system). The DC converter rating was increased from 2000MW to 2300MW in the 2014 CPJA. The additional 300MW converter rating is a pre-investment to allow for economical transmission options for future generation development and to maintain adequate HVDC spare capacity to cover the valve group outages, the most frequently occurred events based on operation experience.

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis		
Discount Rate	% For current corporate rates see G911	For clarification on hurdle rates, contact Economic Analysis Department

Recommended Option	**NPV Benefits/(Costs)**
No Change.	

Other Alternatives Considered	**NPV Benefits/(Costs)**
N.A.	

Risk Analysis – (This section is be filled out only if there is a change to the project risk).

The risk & contingency methodology outlined at the NFAT for Keeyask & Conawapa Projects has been applied to the revised Bipole III Project estimate. The revised estimate includes a recommended Transmission Line project contingency at a P80 confidence level to address remaining areas of uncertainty to the completion of the project and maintain desired in-service date of July 2018.

The previously approved Management Reserve ($100 million) for this portion of the Bipole III complex has been allocated or spent, no further management reserve is not considered necessary at this time.

Risk Analysis – (This section is be filled out only if there is a change to the project risk).

The Transmission Line components require a revised contingency amount of [redacted] for remaining risks and for schedule protection of the July 2018 in-service date. The previously approved $210 million for a P50 (2014) estimate has been allocated as noted in the point estimate (see Background section of this CPJ addendum above). The $100 million in management reserve was approved to be allocated to the two major transmission line contracts for awarded values, and for increases as a result of changes to the Burntwood Nelson Agreement as part of the Converter Stations project.

Remaining risks identified for [redacted] include:

- [redacted]
- [redacted]
- [redacted]
- [redacted]
- [redacted]
- [redacted]
- [redacted]

Total Budget – (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Prev. Approved CPJ/Addendum	Proposed CPJ Addendum	Increase (Decrease)
Prev. Actuals	$ 141,332	$ 141,618	$ 286
2014/15	$ 203,458	$ 125,584	$ (77,874)
2015/16	$ 360,455	$ 345,779	$ (14,676)
2016/17	$ 381,047	$ 549,625	$ 168,578
2017/18	$ 493,821	$ 426,982	$ (66,839)
2018/19	$ 75,257	$ 356,283	$ 281,026
2019/20	$ -	$ 9,676	$ 9,676
2020/21	$ -	$ 2,069	$ 2,069
Total	$ 1,655,371	$ 1,957,616	$ 302,245

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III Project – **CONVERTER STATIONS**

Recommendation (This section is required for all Addendums).

Increase the budget by $106 million for the Converter Station components of the Bipole Project, to a revised total of $2,781 with the in-service date to remain at July, 2018.

Project Scope (This section is be filled out only if there is a change to the scope).

The scope for this portion of the Bipole III complex includes the following major components:

- Design and construction 2300 MW Riel Converter Station and 230 kV AC Switchyard.
- Design and construction 2300 MW Keewatinohk (Keewatinoow) Converter Station and 230 kV AC Switchyard.
- Property acquisition and/or easements for the Riel and Keewatinohk Converter Stations.
- Design & Construction of the Riel Synchronous Condensers.

Changes to scope include: Provincial Road 280, Provincial Road 290 and Conawapa Access Road upgrades.

Background (This section is be filled out only if there is information relevant to the recommendation).

The last project re-estimate was completed in 2014 and incorporated a majority of the project's contract costs and scope updates. The 2014 estimate was based on a P50 confidence level.

The revised estimate incorporates previously out of scope provincial road upgrades and an increase in contingency levels to a P75 confidence level to better address project risks to the completion of the work. There are no other scope changes from the 2014 estimate.

Justification (This section is required for all addendums).

A third 500kV HVdc transmission line with converter stations will provide for increased reliability to the Manitoba Hydro system, due to the critical risk to the Province and the Corporation of a Dorsey Converter Station outage or an Interlake (Bipole I and II) corridor outage. It will also provide an increase in southern power due to reduced line losses on the existing Bipoles I and II (approximately 76MW in normal steady state operation prior to the addition of new generation into the northern collector system).

The DC converter rating was increased from 2000MW to 2300MW. The additional 300MW converter rating is a pre-investment to allow for economical transmission options for future generation development and to maintain adequate HVDC spare capacity to cover the valve group outages, the most frequently occurred events based on operation experience

Risk Analysis – (This section is be filled out only if there is a change to the project risk).

The risk & contingency methodology outlined at the NFAT for Keeyask & Conawapa Projects has been applied to the revised Bipole III Project estimate. The revised estimate includes a recommended project contingency at a P75confidence level to address remaining areas of uncertainty to the completion of the project.

Inclusion of a Management Reserve for this portion of the Bipole III complex is not considered necessary at this time.

Total Budget – (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Prev. Approved CPJ/Addendum	Proposed CPJ Addendum	Increase (Decrease)
Prev. Actuals	$ 318,781	$ 318,781	$ -
2014/15	$ 221,051	$ 198,269	$ (22,782)
2015/16	$ 580,792	$ 468,260	$ (112,532)
2016/17	$ 828,733	$ 955,621	$ 126,888
2017/18	$ 507,689	$ 593,197	$ 85,508
2018/19	$ 195,085	$ 237,967	$ 42,882
2019/20	$ 18,432	$ 8,024	$ (10,408)
2020/21	$ 4,520	$ 574	$ (3,946)
Total	$ 2,675,083	$ 2,780,691	$ 105,609

Proposed Schedule (This section is be filled out only if there is a change to the project schedule).

The schedule remains unchanged with an in-service date of July 2018.

ADDENDUM NUMBER	**DATE** (yyyy mm dd)	**REVISION**	**REVISED BY**	**APPROVED BY**

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).

Bipole III Project – **COLLECTOR LINES**

Recommendation (This section is required for all Addendums).

Decrease the budget by $13.6 million for the Collector Lines components of the Bipole III Project, to a revised total of $246.6 million, with the in-service date to remain at July 2018.

Project Scope (This section is be filled out only if there is a change to the scope).

The scope of this portion of the Bipole III Project remains the same as the previous estimate, with the addition of a secondary communications link between the Keewatinohk CS and Henday.

Background (This section is be filled out only if there is information relevant to the recommendation).

The previous project re-estimate was completed in 2014 and was based on a P50 confidence level.

The revised estimate incorporates a detailed scope based on the actual construction progress to date, reflects current market conditions, and includes the changes noted below. The estimate is based on maintaining a project in-service date of July 2018. The recommended budget for the Collector Lines project is based on a P75 estimate that includes all base costs and contingency at a 75% confidence level.

The Total Net Cost decrease of $13.6M relative to the current approved budget is a result of the following changes:

1. Decrease of $13.0M to forecast escalation and interest.
2. Decrease of $11.0M due to savings in accommodation costs for Long Spruce generating station (GS), Henday converter station (CS) and the AC Collector lines.
3. Decrease of $6.0M in the steel structure costs due to competitive bidding for the AC Collector lines.

These net decreases are slightly offset by the following scope changes:

4. Increase of $6.0M to the construction costs for the installation of the dead end tower footings. Final design was not complete at the time of the contract award; additional towers were required resulting in higher construction costs.
5. Increase of $3.6M for scope changes in the project (several in small amounts) now incorporated.
6. Increase of $2.8M to the construction costs as there was a change in strategy from internal resources to external contracts for the high voltage cable installations and steel modification work at Long Spruce GS, primarily due to the lack of internal resources and expertise for the given scope.
7. Increase of $2.4M for the incorporation of secondary communications link between the Keewatinohk CS and Henday CS.
8. Increase of $1.6M in construction costs as there was a change in strategy from internal resources to external contract for the steel assembly, erection, switch installation and bus modifications at Henday CS, due to the lack of availability of internal resources.

Justification (This section is required for all addendums).

A third 500kV HVdc transmission line with converter stations will provide for increased reliability to the Manitoba Hydro system, due to the critical risk to the Province and the Corporation of a Dorsey Converter

Justification (This section is required for all addendums).

Station outage or an Interlake (Bipole I and II) corridor outage. It will also provide an increase in southern power due to reduced line losses on the existing Bipoles I and II (approximately 76MW in normal steady state operation prior to the addition of new generation into the northern collector system).

The DC converter rating was increased from 2000MW to 2300MW. The additional 300MW converter rating is a pre-investment to allow for economical transmission options for future generation development and to maintain adequate HVDC spare capacity to cover the valve group outage, the most frequently occurred events based on operation experience.

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

Economic Analysis		
Discount Rate	% For current corporate rates see G911	For clarification on hurdle rates, contact Economic Analysis Department

Recommended Option	**NPV Benefits/(Costs)**
No change.	
Other Alternatives Considered	**NPV Benefits/(Costs)**
N/A	

Risk Analysis – (This section is be filled out only if there is a change to the project risk).

The risk & contingency methodology outlined at the NFAT for Keeyask & Conawapa Projects has been applied to the revised Bipole III Project estimate. The estimate includes a recommended Collector Lines project contingency at a P75 confidence level to address remaining areas of uncertainty, and has decreased from the previously approved contingency.

Inclusion of a Management Reserve for this portion of the Bipole III Project is not considered necessary at this time.

The Collector Line components require a reduced contingency amount of $1M from [redacted] to [redacted] in contingency as the project components are further along in construction and reflect remaining risks.

Remaining significant risks identified include:

- $3.2M for potential market rates for the Electrode Lines and R49R Sectionalization.
- $3.0M for potential weather delays increasing construction costs.
- $2.0M for skywire replacement with buried grounding conductor outside of Henday CS to accommodate new overhead lines.
- $2.0M for additional modifications to the Gas Insulated Switchgear at Long Spruce GS.
- $2.0M for additional crews at Long Spruce GS and Henday CS to support the overhead work.
- $1.0M for potential additional costs for 500kV line crossings.
- $1.0M for potential additional costs associated with the installation of the High Voltage cables at Long Spruce GS.
- $0.7M for potential additional construction support from design groups.

Total Budget – (This section is required for all Addendums).

The impact on annual budget requirements is as follows (in thousands of dollars):

Fiscal Year	Prev. Approved CPJ/Addendum	Proposed CPJ Addendum	Increase (Decrease)
Prev. Actuals	$ 33,120	$ 33,120	$ -
2014/15	$ 58,432	$ 34,218	$ (24,214)
2015/16	$ 75,516	$ 63,240	$ (12,277)
2016/17	$ 51,722	$ 60,752	$ 9,030
2017/18	$ 36,708	$ 33,974	$ (2,733)
2018/19	$ 4,653	$ 21,264	$ 16,612
Total	$ 260,150	$ 246,568	$ (13,583)

MANITOBA HYDRO
CAPITAL PROJECT JUSTIFICATION ADDENDUM

Project Name (This section is required for all Addendums).
Bipole III Project – **COMMUNITY DEVELOPMENT INTITIATIVE (CDI)**

Recommendation (This section is required for all Addendums).
Total cost has decreased from $62 million to $56.7 million from the last approved CPJ addendum. [redacted] These costs are now captured in 1.5.2.1.1.1 Transmission Line (in P:04221).

Project Scope (This section is be filled out only if there is a change to the scope).
No change.

Background (This section is be filled out only if there is information relevant to the recommendation).
The total decrease of $5.3 million is as a result of a revaluation of the Present Value of the payments, [redacted] These costs are now captured in 1.5.2.1.1.1 Transmission Line (in P:04221).

Justification (This section is required for all addendums).
The CDI program remains inclusive of a variety of interests; is required as part of Bipole III; and will be an effective means of promoting community support for hosting the Bipole III project facilities

ANALYSIS OF ALTERNATIVES: (This section is be filled out only if there is a change to which alternative is being recommended).

A FILING BY MANITOBA HYDRO TO PROVIDE AN INFORMATION UPDATE REGARDING FINANCIAL RESULTS, FORECASTS, METHODOLOGIES, PROCESSES, AND OTHER MATTERS RELATING TO SALES RATES CHARGED BY MANITOBA HYDRO

Table of Contents

Executive Summary

The Manitoba Hydro-Electric Board ("Hydro") filed a status update with The Public Utilities Board ("the Board") on November 30, 2001. The purpose of the filing was to provide the Board and interested parties with an information update on Hydro, including its financial results, forecasts, methodologies, processes, and events that have transformed the electricity industry over the last few years. Hydro was not seeking any general rate changes, stating that for 2002/03, rates will have effectively been frozen for six years for residential customers and for eleven years for large industrial customers, except for the rate reductions to certain consumers as a result of province-wide implementation of Uniform Rates on November 1, 2001.

Hydro last requested a general rate increase in the fall of 1995, followed by a public hearing in early 1996. The Board's decisions from that hearing are set out in Order 51/96. In light of the long passage of time since Hydro's sales rates were last reviewed in a public forum, the Board determined that one of the purposes of this hearing would be to determine whether the existing sales rates continue to be just and reasonable and whether any changes to existing sales rates may be required.

On February 8, 2002, Hydro announced its intention to acquire the assets and business of Winnipeg Hydro, which had approximately 570 employees and served about 94,000 customers in the City of Winnipeg. The acquisition may have a significant impact on the future overall operations of Hydro.

Hydro believes holding rates constant is a more prudent course of action than offering rate reductions because of the robust export markets and favourable water conditions, which underpinned Hydro's strong financial performance, may not continue at present levels. Rates at or near their current levels will assist Hydro in achieving its longer term financial objectives. Hydro also stated domestic rates are less than market prices in nearby interconnected markets. Current rates are, on average, the lowest of any utility in North America. Lower rates may encourage more domestic consumption, which would reduce revenues as profitable export sales are foregone. Hydro agreed, however, that lower rates could attract more energy intensive industry to the Province.

During the course of the public hearing, the Board examined a number of specific areas related to Hydro's operations including operating results and financial projections, financial targets and risk, capital expenditures, extra provincial revenues, payments to the Province of Manitoba, operating, administrative and finance expenses, transmission tariffs, load forecasts and overall revenue requirements. As a result of this review, the Board identified a number of areas of concern, and made a number of recommendations including:

- Hydro limit its capital expenditures not related to new major generation and transmission, where safety and reliability constraints allow, and focus on reducing long-term debt.
- Hydro pursue short-term financing options to expeditiously pay down the debt incurred for the special export profit payment to the Province of Manitoba.
- Hydro continue to monitor and control operating and administrative expenses.
- Hydro consider ways to diversify and supplement its hydraulic generation with an appropriate mix of other forms of energy.

In addition to the above recommendations, the Board directed Hydro to:

- File an updated Integrated Financial Forecast reflecting the integration of Winnipeg Hydro and the in-service dates of all new generation within the eleven-year planning period;
- File a detailed debt management strategy;
- Undertake a study to quantify specific reserve provisions required to cover major risks and contingencies;
- Undertake a study on the merits of implementing an inverted rate structure for all customer classes;

- Undertake a study on the impact of decreasing the demand charge and increasing the tail block of the energy charge;
- Undertake a study which considers time of use rates for General Service classes based on a seasonal, weekly, daily, and hourly basis;
- Identify and specifically account for all export-related capital expenditures in its capital forecasts to ensure that export revenues are appropriately matched against the full cost of production;
- Undertake a study on the methods and impacts with respect to the classification of generation costs in the Cost of Service Study;
- Re-examine the current level of Demand Side Management programs and pricing strategies to encourage conservation, develop a program with more aggressive targets, and report to the Board;
- Consider the use of wind power in remote diesel electric communities and file a report with the Board; and

A considerable amount of time at the hearing was directed towards a review of the various cost of service studies filed by Hydro, and in particular, the proposed changes in methodology from the methodologies previously approved by the Board. The most contentious issue, and the issue with the greatest impact on cost of service results, is the allocation of net export revenues between customer classes. In this Order, the Board has not accepted Hydro's proposed cost of service methodology. The Board has directed Hydro to file an actual cost of service study for the year ended March 31, 2003 by no later than September 30, 2003 and a prospective cost of service study for the year ended March 31, 2004 by no later than September 30, 2003 which reflects a number of specific directives as set out in the Order including the cost treatment of export classes.

Although Hydro is not seeking any change to firm rates currently charged to customers, the Board noted that certain customer classes have consistently paid rates higher than their allocated costs. Therefore, the Board has directed Hydro to file for Board approval a revised schedule of rates to be effective April 1, 2003 that reflects:

(a) A 1% rate decrease for General Service Small customers;

(b) A 2% rate decrease for General Service Large ("GSL") customers greater than 30 kV; and

(c) A decrease in the winter ratchet to 70% and the subsequent elimination of the winter ratchet effective April 1, 2004.

The Board understands that this change will likely bring the General Service Medium class and the GSL <30 kV class closer to unity. Therefore, no further rate adjustment will be ordered for this class.

Given that uniform rates have provided recent rate decreases to some residential customers and the residential class revenue to cost coverage ratio has been consistently below unity (i.e., subsidized by other classes), no further rate changes are ordered for the residential rate class at this time.

The Board also directed Hydro to file a separate application for approval of an open access transmission tariff by no later than June 30, 2003.

The Board approved the Curtailable Rate Program, confirmed as final a number of interim ex parte Orders, and approved extending the Limited Use Billing Demand Rate option to March 31, 2004.

The Board also directed Hydro to establish a more regular schedule for periodic rate reviews, not exceeding three years between hearings even if no rate changes are required. This timeframe will improve the efficiency, effectiveness and timeliness of the regulatory process.

Subject to these and other specific rate directives contained in this Order, the Board has confirmed Hydro's remaining existing rate schedules to be in effect until March 31, 2006, or until otherwise amended by a further Order of the Board.

1.0 Appearances

R. Peters K. Kalinowsky C. McNicol	Counsel for The Manitoba Public Utilities Board ("the Board")
M. Murphy O. Fernandes P. Ramage	Counsel for the Manitoba Hydro Electric Board ("Hydro")
J. Feldschmid	Counsel for Canadian Centre for Energy Policy Incorporated ("CCEP")
B. Williams B. Froese	Counsel for Consumers' Association of Canada (Manitoba) Inc./Manitoba Society of Seniors Inc. ("CAC/MSOS")
T. McCaffrey	Counsel for Manitoba Industrial Power Users Group ("MIPUG")
M. Anderson	Representing Manitoba Keewatinowi Okimakanak Inc. ("MKO")
E. Fleming	Representing Provincial Council of Women of Manitoba, Inc. ("PCWM")
M. Buchart	Counsel for Time to Respect Earth's Ecosystems/Resource Conservation Manitoba ("TREE/RCM")
C. Henderson	Counsel for Indian and Northern Affairs Canada ("INAC")

2.0 Witnesses for Hydro

V. Warden	Chief Financial Officer, Vice President, Finance & Administration
L. Wray	Division Manager, Business Analysis & Regulatory Affairs
R. Kirk	Corporate Controller
H. Surminski	Section Head, Resource Planning and Market Analysis
R. Wiens	Manager, Rates Department
B. Poff	Manager, Transmission Services
G. Rose	Vice-President, Customer Service and Marketing

5.0 Presenters

J. Knowles	Chief Financial Officer Hudson Bay Mining and Smelting Co. Ltd. ("HBMS")
W. Schroeder	Chief Power Engineer, Inco Limited, Thompson "Inco")
C. Weiss-Bundy	Systems Engineer, Simplot Canada, Brandon Complex ("Simplot")
B. Turner	Plant Manager, Nexen Chemicals Canada Limited Partnership, Brandon Plant ("Nexen")
Dr. C. Nicolaou	Member, Canadian Centre for Energy Policy ("CCEP")

6.0 Background

Hydro filed a status update with the Board on November 30, 2001. The purpose of the filing was to provide the Board and interested parties with an information update on Hydro, including its financial results, forecasts, methodologies, processes, and events that have transformed the electricity industry over the last few years. Hydro was not seeking any general rate changes, stating that for 2002/03, rates will have effectively been frozen for six years for residential customers and for eleven years for large industrial customers, except for the rate reductions to certain consumers as a result of province-wide implementation of Uniform Rates on November 1, 2001. The last time Hydro sought a general rate increase was in the fall of 1995, followed by a public hearing in early 1996. The Board's decisions from that hearing are set out in Order 51/96.

Hydro sought final approval of a new Curtailable Rate Program and numerous interim ex parte Orders dealing mainly with setting the monthly reference discount prices for curtailable service program customers, establishing weekly spot market replacement energy rates under the former dual fuel heating surplus energy to self-generators and industrial surplus energy programs, and establishing weekly spot market replacement energy rates for surplus energy program customers. Hydro also requested final approval extending the Limited Use Billing Demand Rate Option.

A pre-hearing conference was held on January 14, 2002 to define the scope of the hearing, and to establish a timetable for the orderly exchange of information. As a result of the hearing, the Board issued Order 9/02 in which the Board found that, in light of the long passage of time since Hydro's sales rates were last reviewed in a public forum, one purpose of this hearing would be to determine whether the existing sales rates continue to be just and reasonable and whether any changes to existing sales rates may be required.

A public hearing was held on various dates between May 27 and September 30. The Board heard final arguments on June 11, 2002 to deal with the revenue requirement aspects of the application and September 30, 2002 to deal with Cost of Service and Rate Design.

A separate hearing was held to review matters related to the Integration of Centra Gas Manitoba Inc. and Hydro. Order 208/02 dated December 6, 2002 addresses Integration matters.

7.0 Operating Results and Financial Projections

7.1 Comparison of Actual Operating Results with IFF 95-2

The Integrated Financial Forecast ("IFF 95-2") reflected the forecasted financial results of the Board's decisions in Order 51/96. Hydro's actual operating results from 1996 to 2001 and forecast results for 2002 through 2006, as stated in IFF MH 01-1, are compared to IFF 95-2 in the following table:

Statement of Operations & Retained Earnings ($millions)	*Actual*						*Forecast IFF 01-1*

Hydro's operating results since 1996 have been substantially better than forecasted in IFF 95-2. Hydro attributed the improvement in financial position to increased export revenues coinciding with periods of above average water flows, and controls over operating and administrative costs relative to inflation. Actual net income for each of the years 1996 through 2001 exceeded that forecast in IFF 95-2, by $11 million in 1996 to $226 million in 2001. The better than expected operating results have provided retained earnings forecast at $1.15 billion at the end of fiscal

2002, compared to the retained earnings forecast for 2002 in IFF 95-2 of $576 million. On an overall basis, Hydro is now forecasting to have $1.341 billion in retained earnings by March 31, 2006 in IFF MH 01-1 compared to the amount forecasted in IFF 95-2 of $987 million at March 31, 2006.

7.2 Integrated Financial Forecast ("IFF MH 01-1")

Hydro filed its most current financial forecast (IFF MH 01-1) for its electric operations, which included a projected operating statement, balance sheet, financing requirements and financial ratios, as well as a capital expenditure forecast (CEF 01-1) for the eleven-year period 2002 to 2012. The purpose of the IFF and CEF was to provide an indication of Hydro's long-term financial direction and for use in future planning. The forecast was revised during the hearing to reflect the impact of a $288 million payment to the Province and accounting policy changes related to foreign currency transactions including the Exposure Management Program.
IFF MH 01-1 and CEF 01-1 are attached as Appendix A and B to this Order.

IFF MH 01-1 reflects no requested rate increases for fiscal 2002 or 2003, but includes a rate increase scenario of 2% annually for fiscal years 2004 to 2009. Hydro is not seeking approval from the Board for any rate changes in this application, but will file a future rate application with the Board for its approval if rate changes are subsequently determined to be required.

On February 8, 2002, Hydro announced its intention to acquire the assets and business of Winnipeg Hydro, which had approximately 570 employees and served about 94,000 customers in the City of Winnipeg. The acquisition will have a significant impact on the future overall operations of Hydro. The impact of this transaction is not reflected in IFF MH 01-1.

8.0 Financial Targets

8.1 Background

In September 1995, Hydro adopted the following financial targets, which were reviewed by the Board at the 1996 General Rate Application ("GRA").

1. To achieve and maintain a minimum debt to equity ratio target of 75:25 by no later than 2005/06.

2. To achieve and maintain an annual gross interest coverage ratio in the range of 1.20 to 1.35 as soon as possible.

3. To fund all capital construction requirements from internal resources, except during periods when major new generation and/or major transmission facilities are being added to the system.

At that time, Hydro stated that in adopting its financial targets, a number of factors were considered including the following:

- A cushion is required to absorb the impact of negative events so as to maintain rate stability for customers;

- Risks faced by Hydro have been increasing in complexity and size, noting that a major drought could cost in the range of $1 billion;

- Credit rating agencies rely on Hydro's status as a self-supporting utility in determining the Provincial credit rating; and

- Hydro's financial targets are not out of line with the financial position and performance of several other Canadian government owned electric utilities.

These financial targets are consistent with the financial targets included in Hydro's Corporate Strategic Plan for 2002.

8.2 Risks

Hydro has identified a number of specific domestic risks that could have serious financial impacts on its operations including:

- Drought;
- Economic downturn;
- Lower than forecast domestic load related to weather;
- Decreased water flows from increased Alberta and Saskatchewan usage;
- Higher interest rates;
- Higher escalation rates; and
- Transmission or generation system outages.

During a drought, some of Hydro's non-firm export sales would be curtailed, and Hydro could be required to import power to satisfy domestic and firm export load requirements. Imported power would be significantly more expensive. An extended five-year drought has happened three times in the last 86 years. It is Hydro's position that the five-year drought scenario is the most substantial risk, with a possible $1.3 billion negative impact on retained earnings. Other risks could increase this financial impact, especially if they occur concurrent with drought. However, other risks may be non-related, and hence not totally additive. In addition to the threats of water flows, weather, economic and market conditions, erosion of domestic load, major equipment failures, and increased government payments, Hydro's financial position could also be seriously impacted by competition and deregulation in the US.

Hydro has identified a number of specific export revenue risks that could also have a serious financial impact including:

- Economic downturn;
- New gas and coal generating stations coming on line in the US;
- Increased protectionism in the US;

- Changing US legislation and regulation;
- Transmission constraints, mainly in export markets;
- Lower export prices; and
- Open access transmission.

Since export revenues are approximately 40% of total revenue, any risks to export revenues must be considered seriously. With a drought, export revenues will be significantly diminished.

In response to the suggestion of CAC/MSOS witnesses that Hydro prepare a quantitative risk analysis, which would indicate an appropriate amount for required reserves, Hydro noted the breadth and complexity of its risks are vast, and to quantify each risk would be a near impossible task. Furthermore, Hydro stated its many risks are already evaluated and managed throughout Hydro on a day-to-day basis.

According to Hydro, the suggested aggregation of risks goes against including a reserve provision only for foreseeable and measurable contingencies. The nature of risk is precisely that it cannot be foreseen and measured perfectly. While the costs of drought are estimated at over $1.3 billion today, the actual costs of a financial downturn may be greater, depending upon other factors such as domestic load, market prices, supply availability and transmission conditions at that time. In addition, other risks may occur simultaneously with the drought and all costs may have to be recovered through future rate increases. According to Hydro, the current financial targets are designed to provide a cushion to absorb the expected costs of foreseeable measurable risks, with some room to cover unforeseeable contingencies.

8.3 Debt to Equity Ratio

Hydro had a debt to equity ratio in 1996 of 91:09. The ratio has improved to 80:20 in 2001. The improvement is attributable to a growth in retained earnings, rather than a reduction in the level of debt. Total debt, net of sinking fund, increased from $4.8 billion in 1996 to $5.5 billion in

2002, while retained earnings increased from $354 million in 1996 to $1.15 billion in 2002, due primarily to increased operating profits over that forecasted in IFF 95-2.

In its credit rating report dated October 21, 2001, Dominion Bond Rating Services stated, “Hydro continues to generate sufficient cash flows to finance capital expenditures, but there’s little surplus available for debt reduction. … The challenge is that high debt levels weaken most financial ratios.”

Hydro attributed the high-debt level to its significant capital program and that internally generated funds first pay operating costs and then are allocated towards the capital construction program. Furthermore, the acquisition of Centra Gas Manitoba Inc. (“Centra”) and the construction of the Brandon combustion turbine increased debt by $748 million during this period.

Hydro has achieved and exceeded the debt equity ratio forecasted in IFF 95-2 as illustrated in the following table:

	Actual						**Forecast**				
Fiscal Year	**1996**	**1997**	**1998**	**1999**	**2000**	**2001**	**2002**	**2003**	**2004**	**2005**	**2006**
Actual/IFF MH 01-1	91:09	88:12	86:14	84:16	83:17	80:20	77:23	78:22	78:22	77:23	77:23
IFF 95-1	91:09	91:09	90:10	89:11	88:12	87:13	86:14	85:15	82:18	80:20	79:21

In IFF MH 01-1, Hydro originally forecasted to achieve its target debt equity ratio of 75:25 by fiscal 2006 with a 74:26 debt equity ratio. After reflecting the $288 million special payment to be made to the Province, the debt equity ratio in fiscal 2006 is now forecasted to be 77:23, and Hydro will not achieve a 75:25 ratio until 2008. Hydro stated that the current target is not attainable and that there would likely be a recommendation presented to its Board of Directors to establish a new target when the IFF is updated in the fall of 2002.

8.4 Interest Coverage

The Hydro Board of Directors revised the interest coverage target in 2001 from "a range of 1.20 to 1.35" to "maintaining a minimum gross interest coverage level greater than 1.20." Hydro stated that it was important that it operated with a gross interest coverage ratio of 1.20, noting that if it operated at break even, with no margin for adverse events, losses or unexpected costs, Hydro would be required to undertake additional borrowing for interest payments. According to Hydro, capital markets would not have a positive view of an interest coverage lower than 1.20, and operating at a break-even could have a negative impact on rate stability.

Hydro achieved its interest coverage ratio target of 1.20 in fiscal years 1997 to 2000, and exceeded the target in 2001 with an interest coverage ratio of 1.66. The actual results for fiscal 1996 to fiscal 2001 were significantly better than that projected in IFF 95-2 as illustrated in the table below:

	Actual						Forecast				
Fiscal Year	**1996**	**1997**	**1998**	**1999**	**2000**	**2001**	**2002**	**2003**	**2004**	**2005**	**2006**
Actual IFF MH 01-1	1.16	1.23	1.25	1.23	1.35	1.66	1.41	1.21	1.18	1.12	1.13
IFF 95-2	1.13	1.10	1.06	1.02	1.08	1.08	1.12	1.18	1.27	1.27	1.14

The interest coverage ratio is projected to fall below the 1.2 target in 2004 for the remainder of the forecast period as a result of the additional financing costs related to the $288 million special payment to the Province. The gross interest coverage ratio over the 11-year period 2002 to 2012 in IFF MH 01-1 ranges from a high of 1.41 forecast for fiscal 2002 to a low of 1.12 in fiscal 2005, ending at 1.13 in fiscal 2012.

8.5 Capital Coverage

Hydro's target is to fund all capital construction requirements from internal cash resources, except during periods when major new generation or major transmission facilities are being added to the system.

Since 1996, Hydro has funded all capital expenditure from internally generated funds. However, at the end of fiscal 2001, its overall debt had increased by approximately $750 million. Hydro noted that its goal was to fund all capital construction, except major generation and transmission, from internally generated funds. However, there were other expenditures that fall outside the definition of capital construction expenditures that required financing such as inventory, mitigation expenses, vehicle purchases and the acquisition of Centra.

9.0 Capital Expenditures

9.1 Comparison of CEF 01-1 to CEF 95-1

Hydro's Capital Expenditure Forecast CEF 01-1 summarizes an eleven-year program of capital expenditures totalling $3.75 billion, ranging from $425 million in 2002 and declining to $239 million in 2012. This compares with CEF 95-1 total program forecast expenditures of $2.7 billion over the eleven-year period from 1996 to 2006. Over the same eleven-year period, Hydro's actual capital expenditures for 1996 to 2001 and projected expenditures for 2002 through 2006 is $3.6 billion, approximately $848 million greater than that forecast in CEF 95-1, as illustrated in the following table:

Capital Expenditures ($ millions)	**Actual**						**Forecast/Projected**					
For the years ended March 31	**1996**	**1997**	**1998**	**1999**	**2000**	**2001**	**2002**	**2003**	**2004**	**2005**	**2006**	**Total**
Actual/ CEF 01-1 Capital Expenditures	256	297	252	308	310	335	425	367	376	338	330	3,594
CEF 95-1	314	297	285	239	222	207	204	207	220	229	322	2,746
Difference	(58)	0	(33)	69	88	128	221	160	156	109	8	848

At the 1996 GRA, capital expenditures averaged approximately $250 million per year. In CEF 01-1, capital expenditures average approximately $350 million per year.

In CEF 01-1 capital expenditure estimates in later years are less than in earlier years since future capital projects have not yet been identified. Hydro believes that in the absence of fortuitous events, capital expenditures in the later years of the forecast period will be significantly higher than forecast since new projects will be identified. According to Hydro, the higher level of annual expenditures has been, and will continue to be driven, in large part, by distribution system expansions and upgrades, and the repair and replacement of an ageing distribution system.

The capital expenditures forecast in CEF 01-1 do not include Wuskwatim, Gull or Notigi generating stations which are expected to come into service over the next 8-20 years. Hydro has already incurred approximately $367 million in expenditures related to these future capital projects. These expenditures and related financing costs are deferred and will not be depreciated or amortized until the plant or facility is put into service.

9.2 Major Expenditures

Included in Hydro's current capital forecast are the following major projects:

Project	**Total Costs ($ million)**
Brandon Combustion Turbine	183
Brandon Unit #5 Life Extension for Coal	23
Selkirk Conversion to Natural Gas	32
Selkirk Life Extension	29
Interconnection to Rugby ND	25
Radisson-Riel HVDC Line	352
Riel Station	98
Microwave Radio Replacements	141
Planning Studies (2002-2012)	130

Hydro has installed a new 260 MW natural gas combustion turbine at the existing Brandon generating station site. Hydro also plans to upgrade the coal-fired generator to extend its useful life to 2019, beyond its scheduled closing date. Whereas the coal facilities will assist in servicing the domestic load in Southwestern Manitoba, the new natural gas combustion turbines are largely to provide necessary reserve power to facilitate extra provincial sales. The investment in the Brandon combustion turbine is primarily based on increasing the value of Hydro's surplus hydraulic energy that would have otherwise been exported into the short-term opportunity market as interruptible power. After firming up this energy, it can be sold into the more lucrative forward market. The primary benefit of the Brandon combustion turbine is to provide backup power when hydraulic generating capability is reduced during drought or equipment outages. It is expected to operate only 10-16% of the time, while hydraulic generation operates 65-80% of the time.

Citing environmental reasons, Hydro is converting the Selkirk generating station from a coal-fired to a natural gas-fired source of generation, in addition to extending its operating life. Selkirk is also scheduled to operate approximately 16% of the time.

Hydro is also embarking upon an ambitious transmission project which, when totally completed, will result in an additional HVDC line and converter stations on the east side of Lake Winnipeg. The new HVDC line ($352 million) will stretch from the Radisson Converter Station to the proposed Riel Station ($98 million) located outside Winnipeg. An HVDC paralleling line will be constructed to the existing Dorsey HVDC converter station. This will increase reliability and provide an additional 78 MW of capacity due to decreased line losses. This additional power may be sold on the export market. Ultimately two new converter stations will be added at an estimated costs of $400-$500 million each. These are not included in CEF 01-1 since their in-service date is beyond 2012. The total estimated costs for Bipole III are approximately $1.35 billion.

Hydro has forecast spending $130 million from 2002 to 2012 on planning studies for major new generation and transmission projects. In cross-examination, Hydro acknowledged paying for planning study costs commissioned by First Nations communities which will have an equity interest in the future generating stations. Planning studies are capitalized and attract carrying costs that may be significant since these studies are typically undertaken several years in advance of the planned in-service date of the project.

Costs associated with mitigation of environmental and social impacts are not included in the capital forecasts, but are included as a separate expense line item. To ameliorate the adverse effects of hydro-electric projects on the Churchill River Diversion and the Lake Winnipeg Regulation, Hydro has incurred approximately $471 million in mitigation costs. Four of the five First Nations have signed final agreements for compensation under the Northern Flood Agreement, and negotiations for settlement with Cross Lake First Nation are ongoing.

9.3 Justification and Prioritization

Hydro justified its capital expenditures within the following categories:

Justification Category	% of Capital Costs
Capacity	3.5
Load/Reliability	26.5
Safety	0.5
Reliability/Rehabilitation	10.0
Service	2.0
Efficiency	4.5
Other	4.0
Domestic Items*	48.7
	100.0

* Domestic items are non-specific domestic consumer-related expenditures.

Hydro has not attempted to specifically allocate capital costs associated with servicing the export market. Many of the existing capacity and load reliability items (i.e., connection to Rugby, North Dakota) may have an export component and future new generation may be built primarily for the export market. To date however, only the Brandon Combustion Turbine has specifically been justified solely for export purposes. Hydro stated that the majority of capital expenditures in CEF 01-1 have benefits associated with both export and domestic markets.

10.0 Extra-Provincial Revenues

10.1 Industry Changes Impact on Hydro

Over the past six years the North American electricity industry has changed significantly with the introduction of competition at the wholesale level. In response to the issuance of Orders 888 and 889 by the US Federal Energy Regulatory Commission ("FERC") in 1996, open access conditions were made mandatory for transmission carriers, along with a non-discriminatory wholesale tariff, which enabled wholesale competition in the electric industry in the US. By Order 2000, FERC mandated utilities to join Regional Transmission Operators ("RTOs").

The restructuring of the electricity industry in the US resulted in significant opportunities for Hydro, which prompted changes in Hydro's operations to better respond to increased deregulation. In 1996 Hydro reorganized its operations into three business units (Power Supply, Transmission and Distribution, and Customer Service and Marketing) and two support groups (Finance and Administration, and Corporate.)

Hydro's governing legislation was also changed by statutory amendments in 1997, expanding the mandate to include the marketing and supply of power outside the Province. Previously, Hydro's mandate was limited to supplying power adequate for the needs of the Province and promoting economy and efficiency in the generation, distribution, supply and use of electricity.

In response to the new opportunities, Hydro became an active member of the Mid-Continent Area Power Pool ("MAPP"), an electric reliability region and power marketing pool based in St. Paul, Minnesota. With MAPP unable to successfully transform into an RTO, Hydro then joined the Midwest Independent System Operator ("MISO"), which has become an RTO, serving 35 states.

The main consequences to Hydro resulting from electricity restructuring in the US include the following:

- Hydro now sells its transmission service under an open access transmission tariff;
- Significant increases in both the price and quantity of electricity exported;
- Annual export revenues have increased significantly;
- US customers have increased to more than 50 from 5;
- The operation of the main transmission grid is under the oversight of MISO which is responsible for operational reliability; and
- Standards of conduct limit the free flow of transmission information between the transmission operations with Hydro and the wholesale marketers within Hydro.

10.2 Extra-Provincial Revenues - 1996 to 2001

For the fiscal year ended 1996, extra-provincial revenues accounted for $246 million or 25% of total revenues. For the fiscal year ended 2001, extra-provincial revenues were $480 million representing over 40% of total revenue. The major increase in extra-provincial revenues since 1996 was primarily due to the changes in the electric industry with the evolution of competitive wholesale electricity markets discussed above. In addition, the shortage of generation supply caused spikes in prices during the high demand summer periods. This created the opportunity for Hydro to enter into forward contracts for export sales at higher prices. High natural gas prices also added to the volatility of the electricity prices.

Hydro maintains a mixed portfolio of export sales to reduce risk. These export products include long-term firm contracts and short-term opportunity sales. The opportunity sales are dependant upon water flows and can vary greatly from year-to-year.

The table below summarizes export revenues from 1996 to 2001:

Year	Opportunity Export Revenues	Long-Term Firm Export Revenues	Total Export Revenues
	Export Revenues ($ Millions)		
1996	105	141	246
1997	126	142	268
1998	149	148	297
1999	146	180	326
2000	146	230	376
2001	219	261	480

The export revenues, GW.h exported and average sales price per kW.h for the years 1996 to 2001 are as follows:

For the years ended March 31	1996	1997	1998	1999	2000	2001
Revenue $ million(s)	246	268	297	326	376	480
GW.h	10,496	12,531	14,341	10,694	10,776	12,082
Average sale price ¢/kW.h	2.34	2.14	2.07	3.05	3.49	3.97

10.3 Extra-Provincial Revenues - Future Outlook

Hydro stated that price volatility in the MAPP marketplace decreased significantly in 2001 due to the addition of new generation. In addition, the spike in natural gas prices subsided as a result of a downturn in the US economy. With much of the new electricity generated by natural gas combustion turbines, the resulting forward price of electricity decreased significantly in the last months of fiscal 2002. Hydro noted that with a continuance of the downturn in the US economy and lower natural gas prices, it is expected export prices will remain at lower levels in the near term. However, export prices are expected to increase gradually in the long term because of the greater reliance on generation from natural gas-fired combustion turbines in MAPP, rather than generation from coal fired plants with lower fuel costs. In addition, the price of natural gas is forecast to increase in the long term due to high projected demand for natural gas, particularly in the electricity generation sector.

Extra-provincial revenues are forecast to increase to $628 million in fiscal 2002. The major increase forecast for 2002 over 2001 was due primarily to a change in the exchange rate used for translating US extra-provincial revenues, discussed later in this Order. Of the $148 million increase in 2002 over 2001, approximately $110 million relates to the change in the accounting for US export sales. The remainder, approximately $38 million, is due to forecast increases in volumes.

Longer-term sales volumes are forecasted at average levels with revenues of $400 to $500 million/year. Hydro did not provide a breakdown of its future export revenues forecast nor GW.h information for fiscal years 2002 through 2012, since it considers the information to be commercially sensitive.

11.0 Payments to the Province

As a Crown Corporation, Hydro does not pay income tax, provincial sales tax or the Goods and Services Tax. Hydro does, however, pay the Provincial Corporations Capital Tax, similar to other privately held corporations employing capital in the Province. The Province of Manitoba also levies a number of other fees to be paid by Hydro. At the 1996 GRA, annual payments made to the Province from Hydro were in the range of $96 million. Payments to the Province have now increased to $128 million in 2001 and are forecasted to be $354 million in 2002.

The total payments to the Province from 1996 through 2004 are summarized as follows:

	Actual ($ millions)						Forecast ($ millions)		
For the year ended March 31	**1996**	**1997**	**1998**	**1999**	**2000**	**2001**	**2002**	**2003**	**2004**
Debt Guarantee Fee	25	26	29	31	40	49	65	62*	61*
Water Rental Rates	46	50	53	46	46	50	107	96	92
Corporations' Capital Tax	25	26	26	27	29	29	31	31	32
Sinking Fund Service Charge	0	0	0	0	0	0	1	1	1
Special Export Profit Payment ($288 million)	0	0	0	0	0	0	150**	75**	63**
Total	96	102	108	104	115	128	354	265	249

* The impact of the required borrowings related to $288 million special payment to the Province is not reflected.

**Subsequent to the hearing, Hydro's 2002 financial statements indicated that the special export profit payment will be paid out in 2003 and 2004. The first instalment will be $150 million plus an additional amount not to exceed 75% of net income for 2003. The remaining instalment in 2004 will not exceed 75% of net income for that year. In accordance with the legislation, the total distribution to the Province of Manitoba over the two-year period will not exceed $288 million.

11.1 Special Export Profit Payment

In the April 2002 Provincial budget, the Province announced a special export profit payment by Hydro to the Province of $288 million, payable in the amount of $150 million in 2002, $75 million in 2003 and $63 million in 2004. These payments are to be funded from the high export profits Hydro is experiencing and is forecast to continue experiencing. Hydro indicated that general rates would not increase as a result of these payments.

Hydro intends to finance the $288 million payment to the Province since its cash on hand is insufficient to make the payments. The interest costs to finance the payments are estimated to be an additional $276 million during the eleven-year forecast period from 2002 to 2012. As a result of the special payment and additional finance charges, retained earnings is forecast to be over $534 million less in 2012 than that originally forecast prior to the payment. When questioned as to whether Hydro had considered alternatives to financing these payments, Hydro responded it had only considered removing monies from its sinking fund. Hydro had not considered reductions to its capital expenditures nor revisions to its operations, maintenance and administration budgets.

The effect of the special export profit payment on the financial targets is to delay achieving the 75:25 debt equity ratio from 2006 to 2010, and to not achieve the interest coverage ratio target of 1.20 after fiscal 2003 through the remainder of the forecast period to 2012. Subsequent to the completion of the hearing the Hydro annual report for fiscal 2002 indicates that the $288 million will now be taken out in fiscal 2003 and 2004. The first instalment will be $150 million plus an additional amount not to exceed 75% of net income for 2003. The remaining instalment in 2004 will not exceed 75% of net income. Total distributions to the Province are limited to $288 million, under the legislation.

11.2 Water Rental Payment

Hydro pays water rental rates to the Province for the use of water resources in the operation of its hydroelectric generating stations. Under *The Water Power Act* water rental rates increased by over 105% from $1.6285/MW.h to $3.34/MW.h effective April 1, 2001. The effect of this increase was to more than double the water rental fees from $50 million in 2001 to $107 million in 2002.

Hydro had previously negotiated an agreement with the Province whereby water rental rates would be frozen from 1989 to 2001 in exchange for Hydro undertaking a number of northern development initiatives. The total costs to Hydro of such initiatives were $154 million over the 12 years. While Hydro noted the freezing of water rental rates was beneficial to Hydro, it did not plan to negotiate a similar agreement in the future.

11.3 Debt Guarantee Fee

Hydro pays the Province a debt guarantee fee in return for the Province guaranteeing Hydro's long-term debt. Previously set at 0.5% of the outstanding debt guaranteed by the Province, the fee was increased to 0.65% effective April 1, 2000 and 0.95% effective April 1, 2001. This increases the debt guarantee fee from $25 million in 1996 at the last GRA to $65 million in 2002.

Hydro stated that it receives a benefit of 15 basis points in Canadian capital markets and 75 basis points in US capital markets by financing with the backing of the provincial guarantee. All credit rating agency reports point to the provincial debt guarantee as a favourable factor in the credit rating of Hydro.

11.4 Sinking Fund

A sinking fund service charge of 0.075% of the sinking fund is paid to the Province for managing and servicing Hydro's sinking fund balance. This amounts to approximately $1 million per year.

12.0 Finance Expenses

Finance expenses were $426 million in 1996 representing over 46% of total operating expenses. Finance expenses declined to $387 million in fiscal 2001. For the fiscal years 1996 through 2001 actual finance expenses were over $226 million lower than that forecast in IFF 95-2 a result of declining long-term interest rates during the period.

Hydro has forecast finance expenses to increase in fiscal 2002 by $109 million to $496 million or 41% of annual operating expenses. The increase is attributable to an accounting policy change related to the Exposure Management Program ("EMP"), discussed below, additional debt related to the payment of the special payment to the Province, as well as an increase in the debt guarantee fee paid to the Province.

12.1 Exposure Management Program ("EMP")

Hydro employs an EMP which acts as a hedging program intended to limit the Corporation's net US dollar exposure within defined policy limits. Debt denominated in US currency is not subject to foreign exchange fluctuations as the exchange rate used has been fixed in accordance with the EMP. The program is necessary since $2.9 billion or 45% of the Corporation's $6.5 billion in long-term debt at March 31, 2001 is payable in US dollars.

As a result of the EMP, Hydro does not recognize gains or losses related to changes in the US currency exchange rate on its long-term debt or sinking fund. The EMP limits Hydro's exposure to foreign currency changes, and the sinking fund and export revenues act as a natural hedge for the retirement of the US denominated debt. Hydro has estimated that its US cash inflows will exceed the cumulative US cash outflows for interest, thermal fuel and sinking fund payments and will be sufficient to retire the existing US debt by March 31, 2023.

As a result of the program, the long-term debt and sinking fund were recorded at a designated exchange rate of ($1.00 US = $1.17 Cdn), rather than a year-end rate of ($1.00 US = $1.56 Cdn) at March 31,2001. If long-term debt had been recorded at the year-end rate it would have been approximately $1 billion greater than that reflected in Hydro's financial statements. The balance of the sinking fund would have been approximately $200 million greater. US extra-provincial revenues and finance expenses were also recorded at the lower designated rate rather than current exchange rates.

Hydro revised its EMP to reflect a new accounting policy whereby revenues and expenditures resulting from transactions in foreign currencies are translated into Canadian dollar equivalents at exchange rates in effect at the transaction dates except to the extent revenues are used to hedge future long-term foreign debt obligations. Revenues used as formal hedges are firm US revenues which are translated at the embedded exchange rates of the respective US debt obligations to which the firm revenues are linked and for which they, together, form an effective hedge.

Previously, the US based transactions including net export revenues, interest revenues on US sinking fund investments, finance expenses on US debt and fuel purchases were translated at a designated exchange rate of $1.00 US to $1.17 Cdn, an exchange rate significantly lower than the rate of exchange prevailing during the year.

As a result of these changes, Hydro's export revenues increased from $480 million in 2001 to $628 million in 2002. Approximately $110 million of the $148 million increase was due to the change in accounting policy and the remainder, $38 million was due to a forecast increase in the volume of extra provincial sales. In addition, net long-term debt increased by over $403 million in 2003 and finance expenses also increased during the forecast period.

13.0 Operating and Administration Expenses

Operating and administration expenses include the costs associated with operating, maintaining and administering Hydro. Over 72% of these costs relate to labour costs including employee benefits. Hydro reorganized its operations into a business unit structure effective April 1, 1997, resulting in no practical means of comparing individual operating and administrative expense items for fiscal 1996 and 1997 to current expenses. The operating and administrative expenses for fiscal years 1998 to 2002 are as follows:

Operating & Administrative Expenses
($ thousands)

For the years ending March 31,	**1998**	**1999**	**2000**	**2001**	**2002**
Wages, salaries and overtime	205,299	213,732	219,702	259,162	274,079
Employee benefits	46,516	46,782	44,145	49,664	53,963
	251,815	260,514	263,847	308,826	328,042
Travel	18,301	19,992	20,327	22,146	23,302
Material & tools	18,089	18,280	18,674	22,135	22,212
Building and property services	13,967	13,393	13,410	17,221	17,493
Motor vehicle	11,045	12,050	13,048	15,052	12,785
Office and administration	8,358	9,299	9,858	13,604	12,624
Consulting and professional fees	8,151	9,515	8,413	9,229	9,290
Construction and maintenance services	7,765	10,691	8,482	10,242	10,797
Computer services	5,868	5,471	3,920	4,513	4,234
Purchased services	3,897	4,176	6,321	6,794	6,588
Customer and public relations	3,211	4,731	2,436	2,970	3,272
Equipment maintenance	2,761	2,870	3,730	5,096	5,760
Communication systems	1,545	1,586	2,133	2,211	2,242
Consumer services	1,109	1,203	1,339	5,533	5,656
Collections	1,054	1,329	1,445	3,260	2,757
Contingency	-	-	-	-	(1,632)
Operating expense recovery	(11,833)	(5,722)	(7,723)	(11,415)	(11,583)
	345,103	369,378	369,660	437,417	453,839
Less: Capital order activities	(87,280)	(91,617)	(88,065)	(99,660)	(107,814)
Centra costs of operations	-	-	-	(44,000)	(44,900)
Electric costs of operations	257,823	277,761	281,595	293,757	301,125
Less: Capitalized overhead	(45,209)	(54,846)	(53,373)	(50,758)	(46,805)
Total	212,614	222,915	228,222	242,999	254,320

Total operating and administration expenses have increased from $213 million in 1998 to $254 million in 2002. Over the same period of time, Hydro's workforce has increased by 911 equivalent full-time ("EFT") employees, and labour costs have increased by $76 million. This increase in staffing levels and related gross labour costs was largely due to the acquisition of Centra by Hydro and the integration of Centra's employees into Hydro's operations.

13.1 Operating and Administration Costs Per Customer

In the 2002 Corporate Strategic Plan, one of Hydro's stated goals is to improve corporate financial strength. One measure of this goal is to achieve an operating and administration cost per customer (electric) of $600 by March 2003. Hydro stated that the target is a stretch target, calculated based on the average costs per customer in the proceeding five years. By relying on the average of the proceeding five years in calculating the target, productivity increases are automatically built in and accounted for in the target.

IFF MH 01-1 indicates that over the eleven-year forecast period 2002 to 2012, operating and administration expenses per customer are projected to increase from $584/customer to $664/customer. Hydro has stated that to meet the target set out in the 2002 Corporate Strategic Plan, the operating budgets of the various divisions will be scrutinized on an overall basis to ensure the target is met.

13.2 Staffing Levels

Hydro indicated that between 1998 through 2003, staffing levels are projected to increase by 887 effective full time ("EFT") employees, from 4,030 to 4,917 EFT employees. The largest increase in EFT employees occurred in 2001 when staffing levels increased by 704 EFT employees, largely attributable to the acquisition of Centra and the integration of approximately 650 Centra employees.

According to Hydro, the projected level of EFT employees in 2002 and 2003 is optimistic and the actual increase projected for these years may be less. Hydro indicated that the number of EFT positions is closely monitored to maximize efficiency within the Corporation. Hydro stated that any new position has to be approved by the President and is subject to a rigorous process to make sure the position is justified.

13.3 Cost Control Process

According to Hydro, cost control measures are continuous through the utilization of a formalized cost control process that includes planning, budgeting, monthly reporting and variance analyses, which ensures costs and resource allocations are consistent and in line with operating and capital plans. Hydro uses this process to allow management to prioritize programs and projects; manage changing conditions; provide changes in corporate direction; establish communication regarding performance; and react to unforeseen conditions on a timely basis.

13.4 Capitalization of Operating and Administration Expenditures

Hydro segregates costs between operating activities, which are a direct charge against the operating income for the year, and capital activities, which are charged to future periods and amortized over the future life of a respective project. Hydro indicated that employees timecard their activities to specific capital projects. This amount, combined with other related costs, is charged to a capital order. In addition, Hydro also capitalizes overhead by applying the predetermined overhead rates to all capital projects.

Operating and administrative expenses were approximately $454 million in 2002 before capitalized activities and overhead. Hydro indicated that approximately 25% or $107 million would be charged to capital order activities and approximately 10% or $46 million to capitalized overhead. Hydro stated that capitalizing approximately 35% of the total operating and administration expenses was reasonable and was the norm within the industry.

14.0 Transmission Tariffs

14.1 Hydro Transmission Tariff

To ensure access to the lucrative American export market, Hydro complies with certain FERC initiated demands, including reciprocity. Just as Hydro is able to obtain open access to other utilities' transmission systems in the US, Hydro now offers an open access transmission service and levies a transmission tariff to provide for the movement of electricity through Manitoba on its transmission grid. Offered as a service since 1997, the Transmission Tariff has been utilized, on occasion, by other entities and Hydro itself. Under Hydro's standards of conduct, the transmission function is separated from other functions and bills the other business units for use of the transmission facilities. Revenues have been received from use of this Transmission Tariff.

Hydro's Open Access Transmission Tariff has never been submitted for approval by the Board or the National Energy Board, but its associated rate schedules have been filed with FERC in the US. This tariff is based on the FERC pro forma Open Access Transmission Tariff. Approval of this tariff varies across other jurisdictions. Some provincial regulators, such as the British Columbia Utilities Commission, have approved open access transmission tariffs. In the restructured Alberta and Ontario marketplaces, provincial regulators approve provincial based open access transmission tariffs.

14.2 MISO Transmission Tariff

MISO also has its own open access transmission tariff to provide for the movement of electricity from Manitoba into, through, and from a MISO destination. Based on licence plate pricing, whereby the rate charged is that of the destination load zone, this tariff is also a FERC pro forma tariff. The MISO tariff does not apply to the Hydro transmission facilities – rather, it applies south of the border.

This MISO tariff has been approved by FERC, but has not been filed with either the Board or National Energy Board for approval.

14.3 Hydro's Position on Jurisdiction

Hydro noted the legislation is silent as to explicit approvals of transmission tariffs. Hydro argued the MISO tariff was beyond the provincial realm of constitutional division of powers. With respect to the Hydro Open Access Transmission Tariff, the only users are Hydro and parties outside of Manitoba. To retain the flexibility Hydro stated it must respond to rapid changes in the US markets, therefore the tariff should not be subject to direct PUB approval. Instead, the Board would review the tariff at a GRA to the extent that the tariff may affect domestic rates.

15.0 Load Forecasts and Power Resources

15.1 System Load

Hydro's domestic system load forecast is estimated at approximately 3,700 MW net peak demand, and 21,000 GW.h energy for 2003. This is forecast to increase to approximately 4,100 MW peak demand and 24,000 GW.h energy for 2012. Hydro's system load forecast has projected an increase of approximately 18% for energy and 13% for demand for the next 10 years. Over the last 16 years, actual domestic loads have been significantly below base forecasts in 13 of the last 16 years. In the other three years, actual loads have marginally exceeded base forecasts.

With relatively low generating costs and favourable export markets, Hydro is in a relatively advantageous situation to compete on the open market for the sale of power. Therefore, firm contracts negotiated by Hydro provide additional system load demands over and above domestic loads. Available power not required by domestic or firm contract export customers can also potentially be sold in the export market as opportunity sales.

15.2 System Capacity

Hydro currently has approximately 5,400 MW (winter demand) and 25,000 GW.h (annual energy) capability within its hydraulic generation and thermal plants. Hydro has sufficient resources to supply domestic loads and existing firm export sales to the year 2019 under expected load growth conditions.

The capacity criterion for the Hydro system requires that planned generation capacity must not be less than forecast annual firm peak demand plus a reserve requirement of 12% of forecast firm loads. The energy criterion requires that the Hydro system be capable of a dependable supply of energy to meet forecast firm load demands. Specifically, there must be sufficient firm energy sources to meet firm energy demand in the event of a repeat of the lowest historic water flows.

Even with a 12% demand reserve requirement, the demand capability will not be exceeded until after 2020 for domestic load and energy capability will not be exceeded until 2014. Firm exports impose only a modest (100 to 200 MW in demand and 500 to 1,000 GW.h in energy) addition to system capacity and energy demand because the nature of Hydro's firm export contracts (often involving an off-setting import commitment).

15.3 New Power Resources

In accordance with its mandate to pursue sales in the export market, Hydro is bringing new capacity online in 2003 including the Brandon Combustion Turbine. This facility will provide a total installed capacity of 260 MW.

As mentioned in the capital expenditures section of this Order, Hydro intends to embark upon an ambitious construction program over the next two decades with construction of several new generating stations: Wuskwatim (200 MW), Gull (650 MW), Notigi (100 MW), and possibly Conawapa (1,230 MW) which Hydro indicates will be subject to a separate hearing. It is Hydro's contention that new hydraulic generation should be viewed as "green" energy since it produces little or no greenhouse gases. As such, their new hydraulic facilities will contribute significantly to greenhouse gas reductions as contemplated in the Kyoto Protocol. Hydro is committed to maintaining the cumulative average net greenhouse gas emissions since 1990 at 6% below 1990 levels.

Hydro did not distribute its Power Resource Plan citing confidentiality due to the increased competitive nature of electricity trading in the US. Hydro has no wind generation in its current power resources nor plans to install any over the next decade. Witnesses for Hydro agreed the efficiencies and reliability of wind generation have increased substantially while costs have dropped simultaneously over the past few years. However, as yet, wind generation is more costly than Hydro's hydraulic generation, although there may be some other additional environmental and social benefits.

16.0 Revenue Requirement and Current Rates

16.1 Current Level of Rates

Hydro believes holding rates constant is a more prudent course of action than offering rate reductions because the robust export markets and favourable water conditions, which underpinned the strong financial performance, may not continue at present levels. Rates at or near their current levels will assist Hydro in achieving its financial objectives.

Hydro also believes domestic rates are less than market prices in nearby interconnected markets. Current rates are, on average, the lowest of any utility in North America. Lower rates may encourage more domestic consumption, which would reduce revenue as profitable export sales are foregone. Hydro agreed, however, that lower rates could attract more energy intensive industry to the Province.

In IFF 01-1 Hydro has forecast a 2% rate increases in 2004 and each year thereafter until 2009. Hydro indicated these future actual rate increases are at risk of being higher than those projected in the long range forecast in the absence of fortuitous events, such as higher export revenues or higher water flows. Furthermore, according to Hydro, a short-term decrease in rates may simply have to be recovered in future years, potentially leading to rate instability for customers. As rate stability was one of the overriding parameters, reducing and then subsequently increasing rates was not desirable. In response to the suggestion that rates should be set at a break-even level, Hydro stated domestic rates would have followed a widely fluctuating pattern with large rate decreases in 2001 during the windfall years followed by huge rate increases in the subsequent years. As such, it would be neither stable nor predictable.

17.0 Cost of Service Study

17.1 Purpose of a Cost of Service Study

A cost of service or cost allocation study is a tool used to assist in setting appropriate rates to be charged to each class of customer. The Cost of Service Study analyzes the components of Hydro's costs and assigns them to the various customer classes. The purpose of this analysis is to compare assigned costs to revenue by customer classes. The relationship of the revenues from a particular customer class to the assigned costs for that class is the revenue to cost ratio. A customer class where the revenues are equal to the assigned costs, would have a revenue to cost ratio of one. In Order 51/96, the Board stated in part that Hydro "should assume a revised zone of reasonableness target of 0.95 to 1.05" for all class revenue to cost coverage ratios. The results are used to provide guidance in establishing the rate levels and designing the rate structures for each customer class so that each customer class pays its fair share of costs incurred by Hydro to deliver service.

17.2 Methodology

Fully embedded cost of service studies generally employ a three-step process of cost analysis as follows:

(a) <u>Functionalization</u> of costs according to services (or functions) performed by the utility. The major functions by which costs are assigned are generation, transmission, distribution and ancillary services.

(b) Classification of each function's costs according to the system design or operating characteristics that caused those costs to be incurred. In the case of electric utilities, costs are generally classified as one of the following:

- Demand-related costs - Allocated among the customer classes on the basis of demand imposed on the system during specific peak hours, and the maximum size (capacity) of facilities required to service the demand of customers.
- Energy-related costs - Allocated among the customer classes on the basis of energy which the system must supply to serve the customers.

- Customer-related costs – Allocated among the customer classes on the basis of the number of customers, the weighted number of customers, or costs per customer.

(c) Allocation of each functional and classified cost component to specific customer classes based on each class's contribution to the specific cost driver selected.

17.3 1997 Cost of Service Study

Hydro's 1997 Cost of Service Study generally follows the standard three-step process of functionalization, classification and allocation of costs to customer classes. The methodology was last reviewed in conjunction with Hydro's Application for 1996 and 1997 rates. In the resulting Order 51/96, the Board directed Hydro to make some methodology changes, to review a number of other matters, and to report to the Board by no later than the next GRA on a number of issues including the following:

(a) An alternate method of solving the persistent problem of certain subclasses (e.g. Zone 3 Residential and General Service Large ("GSL") being outside of the zone of reasonableness.

(b) The merit of considering GSL customers (over 100 kV) as a separate customer class for cost of service purposes.

(c) An actual cost of service study for 1996/97 on Area and Roadway Lighting to determine actual conditions including the real coincident peak ("CP") factor.

(d) The implications of using incremental versus embedded costs as they would apply to Hydro's rate design, including the impact on various customer classes.

(e) Directly assign DSM costs for General Service Small ("GSS") and General Service Medium ("GSM") customers in future cost of service studies.

(f) Continue with the present net export revenue allocation for cost of service purposes.

(g) Develop a comprehensive rate policy which gives full consideration to all issues related to implementing time of use rates, including off-peak and seasonable rates. The study was also to include the implication of the phase out of the winter ratchet.

17.4 November 2001 Cost of Service Study

Hydro revised its cost of service methodology in the Cost of Service Study filed in November 2001 to:

- Recognize the changes in export energy markets that have taken place in the last several years;
- Recognize the significance of Hydro's participation in these markets to the pricing of its energy and transmission resources;
- Recognize the unique circumstances of Hydro's wholesale customer – The City of Winnipeg; and
- Address issues arising out of Orders 51/96 and 91/00.

17.5 March 2002 Cost of Service Study

Prior to the commencement of the hearing, Hydro indicated it was unable, for reasons of commercial sensitivity, to provide the information necessary to support its November 2001 proposed cost of service methodology. Also, subsequent to the original filing, Hydro and the City of Winnipeg entered into negotiations for Hydro to purchase the net assets of Winnipeg Hydro. Completion of this transaction would eliminate Winnipeg Hydro as a separate customer class and impact the cost of service analysis. As result, on March 27, 2002, and in accordance with Order 52/02, Hydro filed a revised cost of service study that included a number of modifications to its November 2001 filing. The Revenue Cost Average Analysis is attached as Appendix C and the Revenue Cost Variance Analysis is attached as Appendix D.

17.6 Functional Changes

17.6.1 Transmission Assets

In Hydro's 1996 cost of service methodology, all transmission lines and stations (including HVDC facilities) were included in the transmission function and, subsequently, allocated on the basis of both demand and energy. In the March 2002 Cost of Service Study, Hydro proposed a number of changes in the functionalization of transmission assets:

- Hydro's HVDC facilities (with the exception of the Dorsey Converter Station which is considered transmission) are functionalized as generation;
- Only transmission facilities recognized for inclusion in Hydro's Transmission Tariff are included in the transmission function;
- Four sets of AC transmission lines that serve as part of the HVDC collection system in the north to bring the power to the converter stations at Henday and Radisson are functionalized as generation;
- Radial (one way) transmission facilities, including those with voltages greater than 100 kV, are treated as sub transmission and included as part of distribution assets; and
- Local power lines and stations are treated as distribution.

The transmission lines and stations excluded from the transmission function continue to be treated as generation.

17.6.2 Ancillary Services

In its proposed cost of service methodology, Hydro has introduced a new function to capture the facilities and costs associated with providing the following ancillary services:

- Scheduling, System Control and Dispatch
- Reactive Supply and Voltage Control from Generation Sources
- Regulation and Frequency Response
- Energy Imbalance
- Operating Reserve-Spinning Reserve
- Operating Reserve-Supplemental Reserve

In previous studies the costs associated with these services were "bundled" as part of generation and transmission costs. To determine the costs of ancillary function, the assets and expenses associated with providing each of the above services were identified.

17.7 Classification Changes

17.7.1 Generation

Hydro's pre-2001 cost of service methodology classified generation and transmission between energy and demand on the basis of system load factor. The methodology proposed in Hydro's November 2001 study classified generation, transmission and ancillary service separately. Generation costs were classified into four categories: winter energy, winter capacity, summer energy and summer capacity. The classification ratios were to be derived by multiplying the domestic energy and demand forecast by a five-year levelized forecast of Hydro's marginal costs, which, in turn, reflected the export value of capacity and energy.

In its March 2002 revised cost of service methodology, Hydro generally returned to the pre-2001 approach and classified total generation and transmission (along with ancillary services) costs on the basis of system load factor. However, in the revised Cost of Service Study, transmission and ancillary services are classified wholly as demand-related. The balance of the demand-related costs is assigned to generation and all other generation costs are classified as energy related. The result is that 21.2% of generation costs are classified as demand-related.

17.7.2 Transmission

Both the November 2001 and March 2002 cost of service studies classified all transmission costs as demand-related as opposed to classifying then on the basis of system load factor, as previously done by Hydro.

17.7.3 Ancillary Services

Hydro proposes to classify these costs on the same basis as transmission function costs - entirely demand-related.

17.8 Allocation Changes

17.8.1 Generation, Transmission and Ancillary Services Costs

Hydro's pre-2001 cost of service methodology allocated energy-related generation and transmission costs on the basis of annual energy use, including losses between the meter and the generators. Demand-related generation and transmission costs were allocated on the basis of each customer class' contribution to the coincident peak (where coincident peak was defined as the average load during the highest 50 hours of the year). Ancillary services were not separately identified in the previous Cost of Service Study.

In Hydro's March 2002 cost of service methodology:

- Energy-related generation costs are allocated to customer classes based on their share of the overall annual energy requirements (Non-Coincident Peak Methodology);
- Demand-related generation costs are allocated to customer classes on the basis of each customer class' share of the average of the top 50 coincident load hours during the months of December, January and February and June, July and August (2 Coincident Peak Methodology);
- Transmission costs are all classified as demand-related and allocated to customer classes based upon their monthly demands at the time of the system's monthly peaks, with all months given an equal weighting (12 Coincident Peak Methodology);
- Ancillary services costs (all considered to be demand-related) are allocated on the same basis as transmission costs (12 Coincident Peak Methodology).

17.8.2 Export Revenues

Hydro's net export revenues have grown from 17% of total revenues in 1993 to 43% of total revenues as forecast for 2002. As a result, the Cost of Service Study treatment of net export revenues now plays a significant role in the determination of revenue to cost coverage ratios for the various customer classes. For example, the revenue to cost ratio of the "GSL" customer class, based on the proposed methodology in the March 2002 Cost of Service Study, is 1.00, and allocated export revenues are approximately 39% of allocated costs. Alternatively, if export revenues are allocated to the GSL customer class using the methodology consistent with the Board's decision in Order 51/96, the revenue to cost ratio is approximately 1.12, and the allocated export revenues are approximately 49% of allocated costs. Different methodologies for allocation of export revenues can significantly impact customer class revenue to cost coverage ratios.

The previous cost of service methodology employed by Hydro in 1996, and approved by this Board, allocated export revenues as a credit to the various customer classes, based on the generation and transmission costs allocated to each customer class. The previous methodology was based on the premise that it was only the generation and transmission functions which support the export of Hydro's surplus capacity and energy. The revised cost allocation study proposed by Hydro allocates net export revenues on the basis of each class of customer's share of all allocated costs (generation, transmission and distribution).

There was much discussion and debate during the hearing concerning the merits or otherwise of creating a separate export revenue customer class. While acknowledging that creation of an "Export Class" is theoretically possible, Hydro has not fully studied the matter and indicated there were issues, such as the identification of embedded costs, that would need to be determined and whether it is appropriate to include only long-term sales, all firm sales or all export sales in an "Export Class".

Hydro suggests its proposed change in the allocation of net export revenue yields results that:

- Are less distorting of the economic price signals for generation and transmission; and
- Address the Board's concerns as expressed in Order 51/96, including the concerns about class revenue to cost ratios falling outside of the "zone of reasonableness."

17.8.3 Winnipeg Hydro

The November 2001 cost of service filing by Hydro had proposed a number of modifications to the way generation and transmission costs were allocated to Winnipeg Hydro. However, as a result of the acquisition of Winnipeg Hydro, the revised cost of service methodology filed with the Board in March 2002 resulted in the following changes:

- Removal of Winnipeg Hydro as a class of service from the Cost of Service Study;
- Allocation of the costs formerly allocated to Winnipeg Hydro to all the retail classes on the basis of the appropriate allocators; and
- Allocation of the revenues anticipated from Winnipeg Hydro to all the retail classes on the same basis as export revenues.

Hydro's interim adjustment, to the Cost of Service Methodology, for costs and revenues associated with Winnipeg Hydro, was in recognition that the retail customers of Winnipeg Hydro will be incorporated into Hydro's retail classes in future cost of service studies. However, the load and cost data from Winnipeg Hydro was not available to permit such treatment in the March 27, 2002 amended methodology.

Both CAC/MSOS's and MIPUG's pre-filed evidence criticized Hydro's March 27, 2002 amended methodology for the treatment of Winnipeg Hydro as being inconsistent in its treatment of costs and revenues.

In its rebuttal evidence, Hydro acknowledged the inconsistency and suggested that a more appropriate interim cost of service methodology to exclude Winnipeg Hydro as a customer class, would be to subtract all costs expected to have been billed directly by Hydro to Winnipeg Hydro, from generation and transmission costs. Hydro also suggests it would be consistent with the balance of all costs incurred by Hydro's current customer classes.

Hydro has indicated that there is sufficient information available to revise the most recent Cost of Service Study and roughly assign Winnipeg Hydro data to the appropriate classes with a view to illustrating, on a directional basis, the impacts of the Winnipeg Hydro acquisition. A more precise prospective cost of service study for 2003/04 will be prepared.

17.8.4 Implications of Proposed Cost of Service Methodology

The March 2002 proposed Cost of Service Study includes the above-mentioned methodology changes. The results are at considerable variance from the results obtained under the methodology previously approved by the Board. The Revenue to Cost Coverage ("RCC") results under the proposed methodology are significantly affected by the proposed treatment of export revenues and the acquisition of Winnipeg Hydro. The RCC results by overall major customer class are shown in the following table:

Class	RCC Using Previous Methodology (51/96) For Year Ended March 31, 2002	RCC Using Proposed Methodology (March 2002) For Year Ended March 31, 2002
Residential	.884	.965
General Service Small (non-demand)	1.058	1.095
General Service Small (demand)	1.061	1.047
General Service Medium	1.073	1.044
Winnipeg Hydro	1.173	not applicable
Area and Roadway Lighting	.976	1.019
General Service Large	1.108	1.000

17.8.5 Zone of Reasonableness

One product of a cost of service study is a revenue to cost ratio by customer class, where unity, or revenue to cost ratio of 1, indicates that the costs allocated to a class is equal to the revenue earned from that class. The "zone of reasonableness" refers to the revenue to cost ratio range above and below unity that is acceptable. That is, the degree to which each customer class either underpays or overpays their share of allocated costs. Prior to 1996, the zone of reasonableness target was initially 0.85 to 1.15, then 0.90 to 1.10. In Order 51/96, the Board Findings stated in part that Hydro "should assume a revised zone of reasonableness target of 0.95 to 1.05."

The attached table summarizes revenue to cost ratios by major customer classes over the ten year period 1992 to 2002, and highlights certain customer subclasses that have consistently been outside of the zone of reasonableness for a considerable period of time.

Revenue to Cost Coverage – Various Customer Classes
1992 to 2002

PCOSS	1992	1993	1994	1995	1996	1997	1999	2000	2001	*2002

* Hydro's March 2002 proposed Cost of Service Study includes some methodologies, which have not been accepted by the Board.

18.0 Rate Design

18.1 Background

As part of its Status Update filing, Hydro is not seeking any change to firm rates currently charged to customers. Hydro's position is that any Board directed changes and modifications to the Cost of Service Study may impact rate design, and accordingly, the issue of rates should be deferred for future discussions at another hearing. However, Hydro agreed that this regulatory review was a good time to examine rate design issues on a purely principled basis, because Hydro was not requesting any rate changes.

In Order 51/96 the Board directed Hydro to "undertake a study and report to the Board by no later than the next GRA to develop a comprehensive rate policy which gives full consideration to all issues related to implementing time of use rates, including off peak and seasonal rates. This study should include consultation with interested parties and consideration of implications of the phase out of the winter ratchet." It was Hydro's position that matters relating to the problems of subclasses being outside the zone of reasonableness requires regulatory resolution before any other issues related to rate policy and strategy are considered. Hydro also indicated it has no intention of planning any major rate design changes over the next five years.

18.2 Uniform Rates

With the introduction of uniform rates by way of legislation in November 2001, rate zone distinctions for customers on the inter-connected grid were eliminated and all rates in the previous zones 2 and 3 were reduced to be the same as the rate charged in zone 1, which includes the City of Winnipeg. The financial impact of uniform rates is a decrease in revenues of approximately $14.8 million in 2003, the first full year of implementation.

18.3 Residential Rates

The residential rate has a declining block structure which includes a higher energy charge for the initial 175 kW.h and a lower charge for the remaining block. Additionally a basic monthly charge of $6.25 is intended to partially recover costs which do not vary with either demand or energy but which are incurred merely by being a customer on the system. These costs include those associated with billing, customer service, metering, meter service reading, and some portion of the distribution system. Currently the basic monthly charge recovers less than half of these actual costs, the balance of such costs being recovered by way of the energy charge.

18.4 General Service Small Demand and Non-Demand

These customers are the least homogenous of all rate groups. GSS customers are generally small retail and commercial operations. The basic monthly charge of $14.00 for single-phase power or $20.86 for three-phase power recovers substantially more customer related costs than does the residential basic monthly charge. The energy charge is also a declining block rate structure. GSS customers that exceed 50 kV.A are also subject to a demand charge.

18.5 General Service Medium

These rates contain a basic monthly charge, in addition to both demand and energy charges.

18.6 General Service Large

This customer class is broken into three different rate groups, depending upon consumption levels. There are no basic monthly charges for customers in this class. Those customers with the highest consumption levels are charged the lowest rates, because the largest consumers are served off the main transmission system, thereby not using sub-transmission or distribution facilities.

18.7 Time of Use Rates

A time of use rate varies according to the time in which the consumption occurs. During peak periods, customers are charged higher rates and are charged lower rates during off-peak periods. Time of use rates vary seasonally, weekly, daily, or hourly, and even extend to real time pricing. These rates provide a signal to customers of the variable costs of power.

In Order 51/96 the Board directed Hydro to undertake a comprehensive rate design study and include consideration of time of use rates, amongst other things. No such report has been prepared and no movement towards time of use rates is planned by Hydro in the near future. Hydro indicated it is planning to attach specialized meter reading equipment on more customers below the 1,000 kV.A threshold, namely the 250-1,000 kV.A level, of GSL and GSM, which will enable these customers to access time of use rates should Hydro develop such rates in the future. In doing so, this will remove a practical impediment to implementing time of use rates.

18.8 Winter Ratchet

As part of the demand billing process, the monthly billing demand for general service customers is based on actual demand, with a minimum demand equal to 80% of maximum previous winter monthly demand measured in December, January or February. The rationale for the winter ratchet is to signal to customers the high costs of winter capacity and to ensure full winter demand costs are recovered. This issue is problematic for those customers with low off-peak energy usage relative to maximum demand.

The Board is aware that certain customers have been pressing Hydro for a waiver of demand charges during scheduled maintenance shutdowns. Their argument focuses on Hydro's ability to sell this available power on the opportunity export market. Under appropriate constraints with respect to timing and pricing, there could be merit in Hydro offering such a waiver to certain customers.

A report prepared by Hydro investigated alternatives to the winter ratchet including:

- Elimination or substantial reduction of the winter ratchet;
- Gradual reduction of the winter ratchet;
- Replacement of the winter ratchet with higher seasonal and/or peak prices; and
- Waive of the winter ratchet during selected periods.

If the winter ratchet were to be eliminated, the financial consequences would be approximately $3-4 million less revenue annually for Hydro.

18.9 Limited Use Billing Demand

In seeking to address some issues with the winter ratchet, Hydro introduced the Limited Use Billing Demand ("LUBD") rate option in 2000. This allows eligible customers with low energy use relative to demand use to choose an alternate billing process. Under the LUBD program, customers may opt for a lower demand charge in exchange for a higher energy charge. The energy rate for a GSM firm customer is 2.12¢/kW.h whereas a LUBD customer pays 6.92¢/kW.h. The demand rate for that same firm customer is 8.32¢/kV.A whereas a LUBD customer pays 2.08¢/kV.A.

Originally approved for two years commencing June 30, 2000, Order 118/02 extended the LUBD on an interim ex parte basis so it could be considered in this hearing before the Board. Hydro is seeking final approval of Order 118/02 and to make the LUBD rate option a permanent rate offering.

The LUBD rate option is utilized by approximately 120 customers.

18.10 Surplus Energy Program

The Surplus Energy Program ("SEP") replaced the Dual Fuel Heating ("DFH") and Industrial Surplus Energy Programs ("ISE") in 2000. The rationale for those programs was that as a predominantly hydraulic utility, Hydro must plan to have sufficient energy capability to meet the demand of firm customers under the most adverse water conditions. As droughts occur intermittently, Hydro normally has surplus energy available most years. Hydro markets this surplus energy to Manitoba eligible consumers at rates comparable to export prices for similar energy services to enhance pricing options.

The ISE program permitted customers to obtain an alternate supply of energy through spot market energy when Hydro interrupted their supply. The spot market price was based on market conditions considering such factors as import and thermal costs, foregoing export revenues, transmission losses, a margin to account for overhead and administration, and a contribution to retained earnings. A minimum spot market replacement energy rate was in place, in addition to a varying weekly Energy Cost Adjustment and when the Energy Cost Adjustment was required Hydro would file such an application with the Board, on a weekly basis for interim ex parte approval.

The prices for the SEP are based on a forecast of the expected source of energy and associated costs. These are submitted to the Board on a weekly basis for interim ex parte approval, with rates broken into peak, shoulder, and off-peak hours.

At the time of closing arguments, a total of 116 interim ex parte weekly orders had been approved for the DFH and ISE programs, and 96 orders had been approved on an interim ex parte basis for the SEP. Hydro requested final approval of all orders issued on an interim ex parte basis prior to the Board issuing this order. No Intervenors addressed these orders in the hearing. A list of all ex parte orders relating to these programs is attached as Appendix E to this Order.

18.11 Curtailable Rates

Hydro has applied for approval of a new Curtailable Rate Program ("CRP") to supercede the existing Curtailable Service Program ("CSP"). The existing program, originally set to expire November 30, 2001, was extended to February 28, 2002 by Order 150/01 and then again by ex parte Order 55/02, until this Order was released. Hydro proposes the new CRP have a relatively short duration of until November 30, 2003 because the unknown impact of MISO's requirement for and value of reserves.

The CRP allows Hydro to curtail a portion of a large industrial customer's peak load in exchange for reduced rates on that same portion of the load when it was not curtailed. The objective of the CRP is to cut back on the electrical loads during specific periods when the overall electrical system was being taxed to its maximum capacity. As part of the Demand Side Management Program, the CRP reduces Hydro's peak load and assists in maintaining the essential power capacity reserves required for domestic and export operations.

Currently, nine curtailable rate options exist for customers, based on duration and notice for curtailment, in addition to price. Three customers now subscribe to the program, with a total subscribed load of approximately 100 MW. In 2001, the two customers who subscribed to the curtailable rates program saved $1.96 million and $380,000 respectively. Under the proposed CRP, five curtailable rates options will be offered to customers.

Under the proposed CRP, the rationale for curtailments will be altered to only instances required to meet reliability of the system and obligations to maintain operating reserves. There will be no curtailments to enable Hydro to make a high value opportunity sale; curtailments may, however, be made for firm export sales. Additionally, curtailments could occur for forecast errors, loss of facility, and restoring the operating reserve. Curtailments will not be conducted for peak shaving. In 2001, the overwhelming majority of curtailments (26 of 29) were for peak shaving and reducing imports. Since neither of those will be reasons for curtailment in the future, Hydro expects only two to three curtailments per year under the new program, although there will be a maximum ceiling of 3 to 18 curtailments per year depending upon the option chosen.

The financial case for the CRP is based upon an expectation of 150 MW subscribed annually, for a $4.3 million revenue savings to customers. With approximately $1 million attributable to benefits easily quantifiable, the remaining $3.3 million is attributable to reliability benefits not easily quantifiable according to Hydro witnesses. In 1998 (Order 153/98) Hydro presented an application to the Board to alter and extend the Curtailable Service Program. At that time, Hydro indicated there would be $10.4 million in savings to ratepayers if the CRP were extended for a decade. With compounding effects, this would increase to $26 million over that 10 year period. At this hearing, Hydro was unable to provide any tangible evidence whether part of this benefit had been achieved since 1998, noting that by their very nature, these benefits are difficult to quantify and reconstructing decisions made based upon existing circumstances at that time is nearly impossible with intervening events.

The proposed CRP has a reference discount which varies by percentage for each program option. Previously, the benefits had been calculated using the marginal cost values of capacity. The benefit of capacity curtailed over the winter peak was estimated to result from the ability to improve reliability and thus defer the timing of resource requirements. For summer, the benefit of capacity curtailed was estimated to result in increased revenues corresponding to short-term firm capacity sales. Previously the reference discount varied monthly, based on the US – Canadian dollar exchange rate.

In this application, Hydro has applied for a fixed reference discount of $2.75/kW per month, to be adjusted annually for the Consumer Price Index. Hydro has also changed the calculation of the reference discount since Hydro now believes marginal costs are commercially sensitive information and the determination of a value was difficult. Now, Hydro is attempting to use reasonable judgment to balance the lowest value Hydro judges to be necessary to attract sufficient curtailable load to make the CRP work, with the expectation that the load will be available in the long term where the capacity values to Hydro are expected to be higher. Accordingly, Hydro proposes the reference discount be ascribed a value of a reasonable relationship to an alternative least cost resource of capacity, namely a natural gas combustion turbine. In this instance, at $2.75/kW, it is approximately 42% of the levelized cost of the combustion turbine.

With the reference discount previously subject to monthly fluctuations in currency exchange rates, Hydro had filed a number of interim ex parte applications for the CSP. In this application Hydro seeks final approval of the ex parte Orders listed in Appendix E of this Order.

18.12 Diesel Rates

There are approximately 800 customers in the four remote communities of Shamattawa, Tadoule Lake, Brochet and Lac Brochet, who are provided electrical service by diesel generation. These customers are not connected to the main grid due to remoteness of location. In 1997 nine other remote communities previously on diesel service were connected to the main grid. Recent upgrades have permitted the four remaining diesel communities to have similar residential service to those on the main grid with the exception of a prohibition of space and hot water heating.

The current full cost rate for providing diesel service was estimated at 35.9¢/kW.h. Residential diesel customers are charged the same rates as residential grid customers, thereby creating a shortfall of approximately 29¢/kW.h sold. Non-government General Service customers are charged the same rate as grid customers for the first 3,000 kW.h consumed per month and the full cost rate thereafter. Government customers pay the full cost rate. In addition to these full cost rates, all government customers pay a government surcharge intended to recover the deficit incurred by providing grid based rates to non-government diesel customers. The surcharge has been in effect since 1984 and has escalated dramatically to 44.8¢/kW.h. This surcharge is in addition to the full cost rate of 35.9¢/kW.h.

Notwithstanding the government surcharge, a shortfall of $250,000/month is accumulating since the costs of providing service greatly exceed the revenues generated. Up until 2001, the total revenue shortfall was $7.4 million, with a $3.2 million shortfall in 2001 alone.

Since November 2000, in response to a request by MKO, Hydro has billed all First Nations accounts, including government surcharges, directly to Indian and Northern Affairs Canada. In response, Indian and Northern Affairs Canada maintains it provides funding through a formula to the Bands to assist in paying their electricity bills, and returned the unpaid bills to Hydro.

Hydro filed an application for rates for diesel service dated December 2, 2002 and a public hearing is scheduled to commence on March 3, 2003.

19.0 Intervenors' Positions

19.1 CAC/MSOS

19.1.1 Financial Targets

CAC/MSOS questioned the need for Hydro to attain a 75:25 debt equity target to acquire capital at reasonable rates. CAC/MSOS stated the evidence presented by its witnesses, Mr. Todd and Mr. Harper, had confirmed that neither the debt equity ratio nor interest coverage ratios are determinative of Hydro's ability to access capital at reasonable rates. Rather, the key factor in establishing the credit rating is the health of the Provincial finances coupled with the sufficiency of the actual potential revenue streams. Mr. Todd stated neither the interest coverage ratio nor the debt equity ratio should impact Hydro's debt rating nor change Hydro's ability to issue debt, since Hydro's rating is primarily based on the existing Provincial debt guarantee. Mr. Todd noted Hydro's capacity to raise rates, if circumstances warrant, is the key indicator of its ability to meet its obligations in the event of a catastrophe, without posing a burden on the Province.

Further, as confirmed by Standard & Poors, "the existence of a strong and supportive Government and regulatory environment, including a debt guarantee fee, can outweigh somewhat weaker financial indicators." CAC/MSOS noted this was supported by the fact that Hydro's debt rating had remained unchanged, while its debt equity ratio has consistently improved, noting Manitoba still benefits from the same "A" rating now as in 1995 when its debt equity ratio was substantially weaker at 92:8.

Mr. Todd stated there was an inconsistency in Hydro setting an interest coverage ratio of 1.20 to collect an additional $100 million cushion each year, when current reserves of over $1 billion give Hydro sufficient financial protection from a drought. Mr. Todd further stated Hydro need not keep earning net income of $100 million or more annually to be fiscally responsible and that instead of maintaining an interest coverage ratio of 1.20, building reserves even further, Hydro could establish an interest coverage ratio of 1.0, resulting in lower rates set roughly in line with break even over the long run.

19.1.2 Risks

Mr. Todd stated that with more than $1 billion in retained earnings, and 400,000 customers, each customer on average had contributed $2,500 towards that retained earning. As a form of rate stabilization insurance, this was rather expensive according to Mr. Todd, and Hydro is seeking to increase the amount by another 50% to $1.5 billion by fiscal 2008.

Mr. Todd stated it was not sufficient to justify seeking reserves of over $1.5 billion on the basis of a cursory listing of risks. To determine analytically the extent to which it is appropriate to build financial reserves by setting rates that recover more than the normally allowed costs, it is necessary to define clearly the risks being mitigated. Defining the risks involves not only identifying them, but also quantifying the range of possible financial impacts of the relevant risk factors and the likelihood of different possible outcomes. In addition, it is necessary to understand clearly the purpose of mitigating the risk, so an assessment can be made of the appropriate risk tolerance to be adopted for purposes of establishing appropriate financial targets. According to Mr. Todd, risks which cannot be anticipated and built into the forecast should be the only risks requiring reserves.

CAC/MSOS suggested that Hydro's risk analysis consisted of identifying the financial impact of drought at $1.3 billion and then merely listing other risks with no indication as to their impact or likelihood of occurring. Accordingly, such a superficial approach should be rejected in favour of a more vigorous quantitative risk analysis. CAC/MSOS supported its witnesses' recommendations on examining the risks to set an adequate reserve provision by undertaking the following:

1. Determine which risks require reserves – namely unanticipated and therefore not built into the forecast;

2. Consider the magnitude and probability of that risk occurring and recognize the relationship between the risks;

3. Consider the tolerable rate increase should the risks be realized; and

4. Ensure the risk analysis can justify the reserve provision.

19.1.3 Capital Expenditures

CAC/MSOS further suggested the current levels of reserves encourage higher than necessary capital expenditures and that Hydro could operate with a 5% lower capital budget without seriously impacting system capacity and reliability. Furthermore, Hydro's response to a worsening financial situation should be a decrease in capital expenditures rather than merely a requested rate increase.

19.1.4 Operating and Administrative Expenses

The evidence of Mr. Harper, on behalf of CAC/MSOS, suggested Hydro be encouraged to pursue aggressive cost control through productivity improvements to control operating and administration expenses. CAC/MSOS adopted the position of Mr. Harper in closing argument and advocated that Hydro should be evaluated on whether it could achieve annual productivity improvements of 1.5%. CAC/MSOS also suggested there exists opportunities for Hydro to reduce the operating and administration costs per customer.

Mr. Todd and Mr. Harper stated in their evidence that the target level for operating and administration cost per customer for rate setting purposes for the years 2000 to 2012 should be set at $620/customer. Mr. Harper stated the $620 benchmark would reflect a level of productivity typically expected of other regulated activities. Mr. Harper acknowledged Hydro has built in a productivity factor in setting the operating and administration cost per customer target, but suggested that the bar be set higher, more in line with general industry expectations.

CAC/MSOS witnesses stated Hydro's performance in terms of operating costs per customer was in the middle to upper end of the cost range when compared to Hydro Quebec and BC Hydro. They also examined the operating and administration costs in IFF MH 99-1 and IFF MH 01-1, and suggested Hydro has room for improvement.

19.1.5 Load Forecast and Power Resources

CAC/MSOS witnesses highlighted that Hydro has adopted as an energy supply planning criteria that its system be capable of supplying sufficient energy from its thermal and hydraulic stations, under low flow conditions, to meet firm load demands (including firm exports). CAC/MSOS noted forecast export prices should be reflective of the price of natural gas. The cost of gas-fired generation is expected to increase with resulting increased opportunities for Hydro to export power, according to CAC/MSOS witnesses.

19.1.6 Revenue Requirement and Rates

CAC/MSOS argued that although a rate decrease would have been justified prior to the announcement of the special export profit payment, it would now be difficult to recommend one taking into consideration the impact of the payment on the net income of Hydro. CAC/MSOS suggested the Board consider a modest one-time only dividend of approximately 4% to reduce the net income forecasted for 2003.

19.1.7 Cost of Service

CAC/MSOS argued that one of the key questions in the proceedings is whether the Board should accept the narrow view of cost causation supported by MIPUG, or a broader view adopted by Hydro and supported by CAC/MSOS and CCEP. CAC/MSOS pointed out that historically, export revenues were small relative to domestic revenues and costs, and at that time, export prices were less than domestic rates. Under that scenario, applying the principle of cost causality, efficiency, stability and public acceptability made some sense, as did the allocation of export revenues to generation and transmission only. Given the relatively low level of export revenues, this methodology was not distorting and was reasonably reflective of total costs.

CAC/MSOS pointed out that in the recent past, the export market has changed considerably, both in terms of the magnitude of sales, access to the market and Hydro's planning perspective. Net export revenues now offset over 52% of total generation and transmission costs. Mr. Harper stated the costs of generation and transmission allocated to customers have been increasingly underwritten by export revenues, causing an increasing disparity between costs allocated to high-voltage customers served off the transmission system and lower-voltage customers served off distribution.

Export sales now play a more prominent role in the planning and installation of generation and transmission resources, and rates from export sales are now higher than domestic rates in terms of dollars per megawatt hour. As a consequence, all things being equal, an increase in domestic loads will result in required increases in rates to the extent that export sales are reduced. This change in circumstance raises a fundamental question as to the fairness of the cost allocation process, and in the view of CAC/MSOS, a cost allocation methodology conceived in a far different time cannot endure. Mr. Harper stated since all customer classes contribute to the costs of covering risks associated with export revenues, it would be appropriate that all customer classes share in the benefit from net export revenues. Mr. Harper further noted Hydro's proposed methodology accomplishes this and eliminates the significant distortion the previous methodology created between the costs of generation and transmission versus distribution.

CAC/MSOS recommended not pursuing a separate export class at this point of time, suggesting two fundamental problems. The first problem was an analytical weakness, being that the export rates are set by the market, and since the Board has no jurisdiction over these rates, there is a disconnect between the purpose of cost allocation, which is ultimately connected to the setting of rates based on embedded costs. The second problem was a technical weakness, being the difficulties and issues around the question of how to identify and allocate costs between export and domestic customers. This issue is further complicated by issues around commercial sensitivity of certain data related to export revenues and costs. CAC/MSOS acknowledged that although the concept of an export class of customer did not appear feasible or analytically defensible at the present time, that may change when future generation is built for export purposes.

Mr. Harper agreed with Hydro that capacity is the primary factor in determining the overall investment in transmission facilities and agreed that it was appropriate to classify transmission costs as 100% demand related.

CAC/MSOS also supported the allocation of demand related generation costs on a two CP method, which, in their view, is a major improvement in terms of cost causality. Given concerns regarding confidentiality to eliminate the need to rely on marginal costs and export prices to support the Cost of Service Study, Mr. Harper stated that it might also be appropriate to consider using the 12 CP method to allocate demand related generation costs.

CAC/MSOS also supported its witnesses recommendations for the Board to:

- Approve separating the costs of ancillary services from those associated with generation and transmission;
- Direct Hydro to study and report on whether these are alternative approaches to classifying and allocating generation costs that are more reflective of cost causation; and
- Accept the classification of ancillary services as 100% demand related and their allocation on the basis of 12 CP.

Mr. Harper further stated given the materiality of generation in the overall Cost of Service Study and the changes required with the integration of Winnipeg Hydro, it would be appropriate for Hydro to address the allocation of generation before the next GRA. Mr. Harper urged the Board to direct Hydro to study and report whether there are alternative approaches to classifying and allocating generation that are more reflective of cost causation. Mr. Harper further noted it would be inadvisable to adjust the relative rates of the retail customers based on the RCC results presented in the current Cost of Service Study.

19.1.8 Rate Design

With respect to the Curtailable Rates Program, CAC/MSOS adopted the four concerns of its witness:

1. The current reference discount price cannot be justified over the short, intermediate or long term, in terms of net benefit to firm customers;

2. The process for studying the reference discount price is excessively judgmental, which leads to issues of transparency;

3. The application of the load factor is overly generous and overcompensates customers, especially in light of the potential for new customers whose current patterns of usage may differ and diverge materially from the current customers; and

4. Given the uncertainty with MISO, it would be a more prudent regulatory course to continue with the current program until the position of MISO is more apparent.

CAC/MSOS recommended that the reference discount level be set such that it provides real financial benefits to firm customers over a defined period of not more than 10 years, that the reference discount should be benchmarked relative to a publicly available cross-reference that allows the continuing value of the program to be objectively monitored. Mr. Harper urged the Board to direct Hydro change its methodology for calculating the load factor adjustment basing it strictly on the load factor of the curtailable load. Mr. Harper further urged the Board to direct

Hydro to clarify the implications its association with MISO will have on the value of reserves and required terms and conditions, and file a proposal that reflects the anticipated value of the CRP program. CAC/MSOS further recommended that the current CRP should be extended to November 30, 2003, and no further.

On the subject of Uniform Rates, CAC/MSOS recommended that subclasses within the residential and general service categories be maintained, and there be a specific allocation of export revenues to the residential and general service classes to address the class revenue shortfalls arising from the implementation of uniform rates, sufficient to equate the revenue to cost ratios for zone 2 and zone 3 to zone 1.

Dealing with inverted rates, CAC/MSOS acknowledged that although an interesting concept whose time might come, the debate for inverted rates raises more questions than it resolves, and the time for inverted rates has not come yet. CAC/MSOS therefore recommended that the Board should direct Hydro to report back on the feasibility of adopting alternative rate designs, including inverted rates, for all customer classes that would encourage the efficient use of electrical energy, including an implementation plan for those alternatives considered appropriate.

19.2 CCEP

19.2.1 Capital Expenditures

CCEP agreed with the evidence of witnesses of CAC/MSOS that there appears to be less discipline being exercised over the level of capital expenditure as the overall financial position of Hydro improves. CCEP argued that when constrained by increased payments to the province and wanting to maintain financial targets, one option Hydro could explore, other than increasing rates, would be to control the level of capital expenditures. CCEP argued Hydro's capital budgetary requirements could be lowered if targets for export revenues were lowered and environmental initiatives such as the Selkirk fuel switching to natural gas project were deferred until required by legislation. The justification for certain projects was not rigorous enough and as such, some other justifiable projects might be dropped.

Given the potential savings in operating and administrative expenses and capital expenditures and the potential for better than forecast export revenues, CCEP stated there is a possibility that there would be more funds available to provide rate relief to ratepayers.

19.2.2 Extra Provincial Revenues/Operating and Administrative Expenses

CCEP stated Hydro, since the last GRA, consistently underestimated export revenues citing evidence of CAC/MSOS that export revenue projections are likely conservative and Hydro will likely outperform its current financial forecast. CCEP also stated that Hydro could fare better than forecast and realize some $100 million in savings if operating and administrative expenses were held to a benchmark of target $620 per customer in 2012 as proposed by the witness for CAC/MSOS, rather than $664 per customer currently forecast by Hydro.

19.2.3 Payments to the Province

Although outside the Board's jurisdiction, CCEP urged the Board to consider the financial effects of the increased payments to the Province. At $354 million, just over 25% of Hydro's gross revenues are paid to the Province of Manitoba – amongst the highest in Canada. CCEP further stated the Province, as the shareholder of Hydro, has a role to play in assisting Hydro in reaching its appropriate targets without unduly or adversely affecting ratepayers.

19.2.4 Revenue Requirement And Rates

CCEP argued if the Province and Hydro are confident increased payments to the Province are sustainable, then a modest rate decrease of 1% to 2% to the benefit of ratepayers should also be included. This small rate reduction will still provide Hydro with sufficient reserves to face its greatest risk, the possibility of a five-year drought.

19.2.5 Transmission Tariff

In assessing the Board's jurisdiction over the wholesale Transmission Tariff, CCEP urged the Board to view the legislation broadly, and argued that the provision of power should include a transmission tariff as a necessary component of electrical power.

19.2.6 Cost of Service

CCEP stated that they have taken on the mandate of representing the interests of the GSS customer class, a non-residential customer class, whose demand and energy profiles are often similar to residential customers. CCEP also has a mandate to promote better energy policy and understanding of relevant energy issues. Accordingly, although CCEP advocated on behalf of the GSS customer class, it does not do so to the exclusion of improved energy policy.

In CCEP's view, the principles of equity and improved energy policy, in particular the principle that customer classes should pay rates in accordance with the costs of serving that class, require some redress at the earliest opportunity in favour of the GSS class. CCEP pointed out that the revenue to cost "zone of reasonableness" for Hydro customers has been established by the Board between 0.95 and 1.05, and the different cost of service studies reviewed show the GSS customers to be above the zone of reasonableness. The revenue to cost ratio for the GSS customer class, as a whole, is 1.07, and the non-demand sub-class, representing in excess of 40,000 customers, is 1.09. Since the GSS customer class has been outside the zone of reasonableness for some time, and is the only major customer class that remains outside the zone of reasonableness in accordance with the March 2002 study, CCEP strongly advocates immediate redress.

CCEP accepted Hydro's position that the entire Hydro system, including those portions of the system built to support export sales, are built at the risk of all Hydro domestic customers. It is therefore appropriate to allocate export revenues to all functions of the Cost of Service Study, even though the position of the GSS class is nearly unaffected by the methodological change. Accordingly, CCEP disagrees with the MIPUG argument that the GSL customer class pays rates which are even greater than the GSS class, relative to cost of service, since this argument by MIPUG is based on the former methodology of allocating export revenues. CCEP also discounted the argument by certain MIPUG members that electricity costs comprises a large portion of their costs, arguing that issues of economic development and employment policy should not be an issue for cost of service and rate design proceedings.

CCEP argued that if the Board accepts the position of Hydro, supported by CAC/MSOS and CCEP, that Hydro's proposed COS methodology changes, including allocation of export revenues, are appropriate, then the only class continuing to pay more than their cost of service is the GSS class. CCEP further argued that Hydro's proposal to rebalance rates at the next GRA was unacceptable because the ultimate timing of that application was uncertain. Therefore, CCEP requested the Board to direct Hydro to institute a rate decrease to the GSS class at the conclusion of this proceeding of $5.3 million, or 3.8%, in order to bring the GSS class to the top of the zone of reasonableness of 1.05. Alternatively, a rate reduction in the range of $17.7 million or 12.5% would be required to bring the GSS class to unity. CCEP argued that such a rate decrease could be implemented without changing the rates of other customer classes, and with no adverse effects on other revenue to cost ratios.

19.3 MIPUG

19.3.1 Financial Targets

In MIPUG's view, achieving a 75:25 debt to equity ratio and an interest coverage target of 1.20 were laudable goals from an internal corporate perspective. However, they were not appropriate from a cost of service regulatory perspective. The issue to be considered is whether domestic ratepayers should contribute towards achieving Hydro's internal goals beyond that required to enable Hydro to provide safe and reliable electrical service. MIPUG further noted although existing reserves exceed $1 billion, the debt equity ratio would be impacted by the additional debt related to the purchase of Centra, and as a result, rate increases may be required to maintain the debt equity target.

19.3.2 Risks

MIPUG argued that evidence presented by its witnesses demonstrated the existing reserves are more than adequate to achieve the regulatory goals of running the utility and providing a safe and reliable electrical service, and agreed with the witnesses of CAC/MSOS that the existing reserves are beyond what is necessary to protect against the material risks faced by Hydro and are now more than adequate to deal with the risk of drought.

19.3.3 Capital Expenditures

MIPUG argued Hydro's capital program mirrors the rise in export revenues, and capital expenditures increase when export profits are high. MIPUG stated Hydro's capital expenditures have exceeded their 1996 forecast and are now expected to result in $1 billion more in capital assets by 2006 than was expected at the time of the last GRA. MIPUG argued that given the strong export markets, the trend towards acquiring more and more capital assets is likely to continue, and there is not the same level of restraint in controlling capital expenditures that would be required in lean years. MIPUG stated Hydro's decisions about the amount of capital spending increases the burden on domestic ratepayers due to increased interest costs and depreciation in future years.

19.3.4 Operating and Administrative Expenses

The witnesses for MIPUG noted Hydro has been diligent in operating cost control through most of the period under review and that there have not been any increased operating costs, with the exception of fuel expenses, to parallel the increases in revenues. Mr. Osler and Mr. Bowman indicated throughout most of the period since the last GRA, Hydro has functioned with less operating expenses than in the IFF H 95-2 forecast. The witnesses indicated the forecast future increase in fuel expenses is related to exports because the large amount of fuel to be used by the Brandon Combustion Turbine and the Selkirk Generating Station is used to produce power for export purposes.

19.3.5 Load Forecasts and Power Resources

MIPUG expressed concerned about the potential shift in prioritization within Hydro from a domestic supply-oriented utility to an export sales-oriented utility, which discourages domestic use. MIPUG further stated Hydro is first and foremost here to serve Manitobans and low electrical rates can have the benefit of attracting more industry and associated job opportunities to Manitoba. MIPUG urged the Board to be vigilant, noting Hydro has signalled a shift away from a domestic focus, discouraging the use of power in Manitoba in favour of selling into the more lucrative extra-Provincial markets.

19.3.6 Payments to the Province

MIPUG agreed with CAC/MSOS that Hydro's risks are somewhat overstated and Hydro likely will continue to exceed its current revenue targets. MIPUG noted Hydro is nowhere near becoming a risk to the Province. Mr. Osler, who presented evidence on behalf MIPUG, stated that there has been a substantial improvement in Hydro's forecast revenues and financial situation, compared to the forecasts that were provided in the last GRA. Hydro had exceeded its 1996 forecast export revenues over the 10-year period 1996 to 2006 by some $1.63 billion. MIPUG noted the biggest beneficiary from this improved financial position continues to be the Government of Manitoba rather than domestic ratepayers. MIPUG noted that payments to the Province have increased by $800 million over the 10-year period 1996 to 2006, approximately half of the additional $1.6 billion in export revenues, of which only 11% had actually gone to the general benefit of customers through foregone rate increases.

MIPUG suggested increasing payments to the Province is another risk faced by Hydro and that given the increased payments, the Province does not appear overly concerned with the current progress Hydro makes towards reaching its financial targets. MIPUG is satisfied Hydro could adequately address its risks, even with these increased payments to the Province, and further noted that increased equity levels would likely benefit the Province and not the ratepayers - something MIPUG urged the Board to consider in setting rates that may contribute to increased equity levels.

19.3.7 Revenue Requirement and Rates

MIPUG argued when forecasts are scrutinized, it is apparent that rates should not be increased. In addition, MIPUG argued there is some room for a rate decrease based on the fact that the future outlook suggests that the financial expectations of Hydro will be surpassed and that the current reserves are sufficient to protect customers without requiring them to contribute unnecessarily to the achievement of financial targets. Further, MIPUG argued Hydro has not discharged their onus of establishing that the overall level of rates are just and reasonable.

MIPUG argued that the revenue requirement was overstated by Hydro, the existing level of reserves are more than adequate, and rate decrease in the amount of approximately $15 million could be achieved without increasing rates to other customer classes.

19.3.8 Transmission Tariff

MIPUG argued that since power was not part of the transmission service, the Board's jurisdiction over the tariff did not exist because the Board's jurisdiction was confined to reviewing rates for service for the provision of power.

19.3.9 Cost of Service

MIPUG asserted that Hydro's sales rates have long been set based on the principle of cost causation, and the Board, in fulfilling its responsibility to determine whether the rates charged by Hydro are just and reasonable, must consider the evidence in support of Hydro's revenue requirement and Cost of Service Study. MIPUG further stated that the principle of cost causation has long been used in this jurisdiction because it works, and because it satisfies the ratemaking principles of rate stability, predictability, transparency and public acceptability. MIPUG further argued that the cost causation principle has been refined over the years, has stood the test of time, and there is no reason to depart from that principle today.

With historic revenue to cost ratios generally exceeding 1.05, MIPUG argued for a rate reduction of $15 million to comply with Order 51/96 and to bring the "GSL greater than 100 kV sub-class into the zone of reasonableness. MIPUG argued that a rate freeze does not address the problem of a sub-class paying rates that chronically exceed costs. The witnesses for MIPUG stated there is a demonstrable need and opportunity to provide substantive rate relief to industrial customers who have been paying rates above costs for more than a decade. MIPUG believes the time for solution is now, not only because rate relief for the sub-class is overdue, but also because Hydro's favourable financial situation at the present time creates an opportunity to make progress in bringing the sub-class towards the zone of reasonableness without negatively impacting other customer classes. MIPUG argued that there should be no further delay in rate relief.

MIPUG supported its witnesses' position that some changes to Hydro's Cost of Service Study have departed from cost causation, most notably the treatment of export revenues. The change in the methodology to allocate export revenues is also based on the premise that domestic rates in Manitoba are already as low as they need be, which in MIPUG's view, is a premise that has not been tested or accepted by the Board. MIPUG further argued that no other regulated jurisdiction sets rates other than on cost based principles, and that cost based principles are resilient enough to apply to a range of changing circumstances, including a large increase or decrease in export revenues, and the future construction of Wuskwatim for export purposes. The witnesses for MIPUG stated that it is apparent that the revised methodology has mathematically achieved what Hydro has been unable to achieve through rate revisions over the past decade. MIPUG believes that a primary motivation for Hydro to depart from a cost based allocation methodology is Hydro's desire to bring the revenue to cost ratios for all subclasses closer to unity without having to reduce rates.

In MIPUG's view, the established practice of allocating net export revenues to generation and transmission is consistent with the costs of getting those export sales in the first place. Since generation and transmission are the only functions responsible for supplying the power to the export market, the revenues earned from the export market should be used to offset those costs. In addition, since all Hydro customers use the generation and transmission assets, all customers do receive a benefit from the export revenue allocation, in proportion to each customer classes use of those assets.

MIPUG stated that the non export revenues related changes to Hydro's cost of service methodologies have a relatively minimal impact on the revenue to cost ratios of the subclasses in comparison to the changes in allocation of the net export revenues. The witnesses for MIPUG stated the proposed changes to the Cost of Service Study methodology dramatically redefines the measurement of costs to service customer classes and serves to shift material net costs away from residential customer classes onto industrial customer classes.

MIPUG does not support the creation of a separate export customer class, noting the difficulty in identifying the embedded costs associated with earning the export revenues. MIPUG suggested that the Board could direct Hydro to study further the issue of embedded costs for export revenues, but noted that Hydro was directed to do this in 1999 and did not do so. MIPUG requested that the Boards decision on this matter should not delay the issue of immediate rate relief.

The witnesses for MIPUG noted there is a minimum basis to adopt any of the proposed changes to the Cost of Service Study methodology and that the past cost of service practice remains suitable for the present domestic situation, and therefore recommended retaining the previously approved cost of service approach. The witnesses further stated that the classification of transmission costs on a basis of 100% demand (based on a continued allocation using a 1 CP methodology) may have merit. In addition, they recommended the assignment of some level of "system dividends" to all customers limited to net export revenues net of all embedded costs to serve these loads. However, MIPUG stated the proposed changes to not functionalising HVDC to generation, changes are perhaps not necessary, they can be supported by cost causation, and therefore, MIPUG is not opposing the proposed change. MIPUG also believes that the previous method of classifying each of transmission and generation on the basis of system load factor is preferable over the complicated and unprecedented two-step classification approach proposed by Hydro.

MIPUG also argued that there is only one key time of the year which drives the costs on the Manitoba system, and that is winter. Therefore, under the cost causation principle, the only approach that relies on established principled rationale is the retention of the 1 CP method, based on winter peak load, for both transmission and generation.

With respect to the treatment of Winnipeg Hydro costs and revenues as export sales, MIPUG's witnesses stated this ignores that Winnipeg Hydro's costs and revenues are matched with both entirely related to generation and transmission. Instead, Hydro's proposal results in the costs previously allocated to Winnipeg Hydro's being reallocated back to other customers on the basis of generation and transmission, while the revenues are reallocated back to other customers on the basis of generation, transmission and distribution. This fails to maintain the matching of costs and revenues and fails to reflect cost causation. Accordingly, there is no basis to adopting this interim approach.

19.3.10 Rate Design

With respect to the CRP, the witnesses for MIPUG stated the CRP continues to be the most substantial capacity related Demand Side Management program offered by Hydro and continues to provide value to the utility and its customers in terms of reliability and support of increased high-value firm export sales. MIPUG argued that although the program is relatively small program compared to Hydro's firm rate offerings, it is none the less an important program for certain large industrial customers and strongly supported approval of the Curtailable Rates Program on a permanent basis, subject to the reference discount being adjusted to remove the 12% reduction, to revert to an 80% equivalency factor, and to re-introduce the U.S. exchange rate for the summer generation portion of the benefits.

19.4 TREE/RCM

19.4.1 Capital Expenditures

TREE/RCM argued that Hydro's capital requirements could be lowered if appropriate incentives for reduced energy usage were put in place. With enhanced energy efficiency major new transmission and generation would be unnecessary.

19.4.2 Extra Provincial Revenues

TREE/RCM commended Hydro for its efforts in expanding export sales and stated Hydro had been successful in exploiting opportunities in the North American energy market through their initiative and would like to see Hydro apply such similar talents and skills to an aggressive demand side management policy. TREE/RCM noted that an aggressive demand side management policy and the inverted rate structure may be unduly harsh on the 35% of households in Manitoba reliant on electric heat and that some revenues would be required to mitigate these effects in the short run. Accordingly, some revenues from the export market should be used to enhance energy efficient installations in Manitoba homes.

19.4.3 Load Forecast and Power Resources/Revenue Requirement and Rates

TREE/RCM argued the Board should consider the conservation interest and sustainable development in its rate-setting, and realize that low rates are not necessarily the only or even prime consideration in determining rates. TREE/RCM argued for an overall rate increase to enhance the revenue requirement such that the additional monies could be used for conservation purposes, to enhance DSM programs for residential customers, and, in particular, to finance the transition to the inverted rate structure, especially for residential customers reliant upon electric heat.

19.4.4 Rate Design

The intervention by TREE and RCM was to examine Hydro's operations and rates for their impact on energy conservation and consequent impacts on local and global eco-systems. TREE/RCM stated that Hydro has sales rates that are amongst the lowest in the world, and generally speaking, low rates have a negative impact on energy efficiency because it is affordable to waste energy. Peter Miller, a witness appearing on behalf of TREE/RCM, noted because of the low rates, it is more cost effective, or at least affordable, for the consumer to waste energy than to spend money on energy conservation. TREE/RCM's objective is to get Hydro to adopt policies that better promote principles of sustainability, emphasizing energy conservation and environmental impact reduction and mitigation. Peter Miller, on behalf of TREE/RCM, stated in setting rates Hydro should interpret its mandate as being to secure the best possible "triple-bottom-line" including social, environmental and economic outcomes in its operations. TREE/RCM argued that despite well-expressed intentions, Hydro has not been aggressive in their DSM efforts and in promoting conservation and efficiency.

TREE/RCM brought forward Mr. James Lazar, a regulatory consulting economist, as a witness to address the benefits of adopting an inverted rate structure for residential customers. This would have an initial rate inversion based on the low cost power on the older Winnipeg River System which has no high cost lengthy HVDC transmission lines. It would then be enhanced by an additional rate inversion based on the relative load factors of different size residential customers, which consumes higher cost more modern Northern generation with associated lengthy transmission facilities.

Mr. Lazar, appearing on behalf of TREE/RCM, proposed the adoption of an inverted rate structure. The structure provides each customer a limited amount of power at one lower price per kilowatt hour and additional usage provided at a higher price per kilowatt hour. This contrasts with the current rate structure utilized by Hydro; a declining block structure, where larger customers pay a lower rate per kilowatt hour than smaller customers. Mr. Lazar noted that an inverted rate structure would be appropriate in Manitoba because it communicates the fact that the utility has only a limited supply of low-cost power and distributes the benefit of low-cost hydro resources uniformly among customers while the current declining block rate structure gives the largest users the largest share of the benefit.

Mr. Lazar further stated the inverted rate structure was most appropriate for Hydro, because it has two very different sources of power supply, including the older system on the Winnipeg River that provided a limited supply of low-cost power that could be recovered by the lower block rate and newer more expensive facilities in the north which provide a larger supply of power at higher debt service costs on dams and transmission, that could be recovered at a higher block rate.

Mr. Lazar recommended the following changes be made to implement an inverted rate structure:

- Flatten the customer demand charge to $6.25/month regardless of the connected average.
- Provide each customer an initial block of 250 kW.h/month at a rate of $0.02/kW.h lower than the rate for additional usage. Any further revision could await cost studies on the amount of low cost power and how to distribute export profit.
- Hydro undertake a stratified load research study of its customers and their respective end use electricity to determine if large use customers have a diversified load factor that is different from small customers to develop de-averaged distribution rates.

Mr. Lazar stated the impact on residential customers would result in those using less than 250 kW.h/month realizing a rate decrease of 32%. Large use residential customers (3,000 kW.h/month) would receive an increase of 8% noting further that very few customers would see large changes to their bills. However, as a result, all consumers would have a greater incentive to conserve electricity. Mr. Lazar stated the benefit of such a structure would be approximately a 4-5% less usage per customer than the current residential rate design.

Citing the principles of the Sustainable Development Act which TREE/RCM argued was applicable to Board decisions, TREE/RCM made nine recommendations as follows:

1. An explicit goal be added to the Power Smart program to increase the eco-efficiency of the energy supplied by Hydro.
2. Adopt methods for measuring absolute and relative efficiency performance for different customers and end use classes.
3. Consider for adoption comparative efficiency performance measures.
4. Adopt a more aggressive conservation program for the residential sector.
5. Create a rate regime in which each customer faces tail-block rates that are much closer to the marginal costs of electrical demand and energy.

6. Hydro be directed to file an inverted rate for residential customers holding the customer charge to $6.25, providing the first 250 kW.h block of power at a rate of $0.038/kW.h and additional power at the level needed to make Hydro revenue neutral, estimated to be approximately $0.059/kW.h. Alternatively, the Board could direct Hydro to file an inverted rate structure to give a larger low-cost block to all electric residential customers. A third alternative would be to have a minimum bill to replace the basic charge.

7. Hydro be directed to prepare load research on the relative load shape and load factor of large versus small use residential customers on the generation, transmission and distribution system.

8. Hydro be directed to study options for general service rate design changes to improve the efficiency of pricing information to customers.

9. Hydro be directed to implement an energy efficiency grant program funded from initially up to one quarter of the net export revenues.

TREE/RCM believes that adoption of their recommendations will strengthen the economy of Manitoba and reduce the adverse environmental impacts of energy production and consumption in the region and globally.

19.5 MKO

19.5.1 Rate Design

MKO stated that with the exception of the hydroelectric operations on the Winnipeg River, all of the existing and planned hydroelectric stations of Hydro are within the MKO region and directly affect the rights, interests, communities and traditional territories of the 12 MKO First Nations. MKO generally supports the basic principle of uniform rates established by legislation effective November 1, 2001. MKO further stated that, in respect of the rate rebalancing proposed by some interveners, as long as rates are less than those approved to be effective November 1, 2001, it appears doubtful the Board can alter the rates that went into effect after November 1, 2001 until Hydro applies by way of a GRA to change rates.

With respect to diesel rates, MKO argued that the First Nations communities do not have the financial resources to pay their electricity bills that are being assessed, which creates a circumstance that must be addressed. Although all residential customers in the diesel communities do pay the equivalent zone 1 rate, all consumption over 3,000 kW.h for non-government customers and First Nations facilities are assessed a surcharge, which in the view of MKO, is not consistent with the legislation. Therefore, the intent of uniform rates should be extended to all remaining customers in the diesel communities and all ratepayers, regardless of geography to pay the same rates. MKO further argued that Hydro has not exercised its duty to diesel community customers to promote economy and efficiency in the use of electricity. On that basis, customers have been exposed to substantial costs, and Hydro should assume the costs to the remaining customers in the diesel communities, and provide benefits to those customers that are being shared by other Manitobans.

MKO also suggested that Hydro should aggressively promote demand side management initiatives in the diesel communities, as well as seek alternative sources of supply to serve the communities in a more cost effective way.

MKO issued a subpoena to Mr. Fred Mills of Indian and Northern Affairs Canada to discuss the nature of the funding provided by Indian and Northern Affairs Canada to First Nations in respect of electricity costs. Mr. Mills testified that a formula pays for what is, in essence, a nominal amount of the electricity bills incurred by all First Nations government accounts, which could include schools, police stations, band offices, social services offices, etc. Mr. Mills also testified that Hydro and Indian and Northern Affairs Canada are really not involved in trying to resolve issues arising out of diesel rates.

19.6 PCW

19.6.1 Rate Design

PCW did not speak to the specifics of the status update, but expressed particular interest in the future regulation and public accountability of Hydro. PCW expressed concern for the increasing instances where the Government of Manitoba has denied Manitobans the opportunity for public scrutiny, and referred specifically to the implementation of Uniform Rates, the increases in government charges to Hydro, and the acquisition of Winnipeg Hydro, all done outside of the scrutiny and review of the Board. PCW argued that by far the most effective oversight of Hydro is by public process directed by the Board, and expressed concern that it took over six years for Hydro to apply to the Board for this Status Update hearing. PCW also expressed concern as to what future legislation the government might introduce to further diminish the Board's oversight role.

PCW endorsed the Board's role as a proxy for competition, and stated that Manitobans need regular review of Hydro by an informed watchdog, looking out for the public interest. PCW requested the Board to consider the timing of future reviews of Hydro.

20.0 Presenters' Positions

20.1 HBMS

HBMS is a base metal mining, smelting, and refining business in northern Manitoba. Together with the Mining Association of Manitoba, in 1999 HBMS proposed a variable rate structure that would strengthen its operation in low price periods and share the benefit of high price periods with Hydro. Applying this approach to multiple industries would diversify the utility's risk while ensuring continued strength of the Province's major economic drivers and Hydro customers.

HBMS argued that large power users in this Province have paid a disproportionate portion of the rates charged to Hydro customers over the last decade Hydro's industrial rates should more closely reflect the costs of producing and delivering electricity. A 10% reduction of GSL (over 100 kV) rates, to reflect more closely Hydro's actual cost of service, would have significant beneficial effect on any decision for future energy-intensive capital projects and improve the allocation of rates in the Province and enhance the long-term strength of significant customers and economic drivers of the Manitoba economy.

20.2 Inco

Inco, is a nickel mining company in Thompson. Inco stated increased debt guarantee charges, water use rates, and other cash extractions have resulted in a net transfer to the Manitoba Government. Inco stated that short-term export profits or long-term direct employment in Manitoba is a government policy choice. The 1,400 direct jobs, the support services jobs, and the revenues that they create for Hydro, as well as the taxes this employment generates affects Inco's competitive position. Inco believes that leveraging electricity rates to create and maintain jobs is paramount to protect the ratepayers from volatile energy markets.

Inco pays a demand charge winter ratchet for unused electricity in their scheduled summer shutdown. However, this electricity is sold again on the spot market. Inco suggested that Hydro stop charging twice for the same products.

20.3 Simplot

Simplot is an integrated fertilizer plant which manufactures nitrogen and sulphur based fertilizers as well as a limited range of industrial nitrogen products. Simplot submitted that Hydro costs and rates must remain subject to rigorous examination by the Board. Simplot is concerned that, while Hydro is not requesting a rate increase with this submission, it appears to be positioning itself for a series of rate increases over the immediate future. Simplot was disturbed that the provincial government continues to increase its revenues through special levies on Hydro.

The apparent shift in Hydro's priorities, away from its domestic customers to its export sales is of concern to Simplot. This shift has resulted in Hydro's stated position, in this filing, that domestic electricity rates are "as low as they need to be", and the further assertion that failure to recognize the real value of electricity (i.e., export value) could result in the diversion of energy from profitable export sales to energy intensive domestic industries.

Simplot, together with other members of MIPUG, have maintained that Hydro's rate structures impose an unfair burden on the GSL (over 100 kV) rate class. Hydro's response to the Board's Order, as evidenced by its Prospective Cost of Service Study, has been to develop a new method of service calculation to bring all rate classes with the zone of reasonableness, rather than to adjust the rate structure itself. Reducing firm power costs by 11% would significantly improve the competitive position of all large industrial power users in Manitoba.

Simplot optimistic that Hydro will be able to agree on a proposal that would provide Simplot and other large industrial customers some relief from the demand charge winter ratchet during scheduled plant maintenance shutdowns.

20.4 Nexen

Nexen uses an electrolytic process to produce sodium chlorate, which is used to bleach wood pulp. Nexen requested that the Board consider the presentations made by MIPUG in light of the competitive challenges faced by Nexen, and other energy intensive industries in Manitoba, and help them retain their competitive positions Nexen is currently a curtailable rate program customer. In 1998-2000, Nexen participated in the Industrial Surplus Energy program. However, as export power prices continued to rise, Nexen could not justify participating in the program. The introduction of Curtailable and Industrial Surplus Energy programs in the latter years has also been a positive factor in convincing Nexen's Board of Directors that expansions should occur in Manitoba. Dedication to providing reliable firm power at fair and reasonable rates that reflect cost of service and commitment to innovative rate options that benefit both industry and Hydro are important for the future growth of large industry in Manitoba.

Competitive power rates encourage new growth in the industrial sector. In 1994, the Board's direction to move firm industrial rates as close to cost as possible, and the subsequent 1994 reductions in provincial taxes on manufacturing energy purchases have both had significant positive impacts on Nexen's production in Manitoba, and in Nexen's commitments to capital expansion in this province.

20.5 Presentation of C. Nicolaou

Dr. Nicolaou, a Professor of Economics at the University of Manitoba, stated that the GSS class needs serious attention by the Board. Rates for the GSS class require modification to relieve the sector from a long-term burden.

Growth prospects of the Province rest squarely upon the small business sector. The typical small business is often, by its nature, ill-prepared to deal with adverse conditions. Without pressure from the unrepresented small business sector, and without representations to the Board, the small business sector has the highest revenue cost coverage above the Board's zone of reasonableness. Small business over pays $15-17 million annually.

The simplest, most direct and immediate redress of this long-term disadvantage imposed on small business is for Hydro to be ordered to lower rates for GSS, to bring the RCC to unity. The current and long-standing overpayment by the small business sector must end immediately. However, even this measure would not return past overpayments. Relief should be given to the class which is not only crucial for Manitoba's economic development but is also in need for even the smallest amount of assistance.

21.0 Board Findings

21.1 Operating Results and Financial Forecasts

The Board notes that for the fiscal years 1996 to 2001, Hydro has experienced actual financial results that are dramatically better than the results forecasted in IFF 95-2. The improvement in Hydro's financial results is due primarily to favourable water levels and market conditions, and the successful implementation of a strategy to develop extra-provincial sales opportunities. The Board commends Hydro for its proactive approach and effective execution of a strategy to capitalize on and adapt to the changes in the export market, brought on in part by the introduction of competition in the wholesale export market. Through membership and participation in MAPP, MISO and other key committees and organizations, and proactive marketing efforts, Hydro has been able to represent its interests and more than double the revenues related to extra-provincial sales since 1996. This has resulted in record profits, improved financial strength and stable rate levels for Manitoba consumers. The Board encourages Hydro to continue its active participation in MAPP and MISO and marketing efforts, which have resulted in benefits to Manitoba ratepayers.

Extra-provincial revenues now have a greater prominence within Hydro than in 1996, representing an increasingly significant portion of Hydro's total revenues. Risks related to losing those revenues have also increased substantially since 1996.

The Board notes that IFF MH 01-1 is based upon many assumptions which are beyond the control of Hydro. In the Board's view, IFF MH 01-1 represents a conservative forecast using reasonable assumptions. The IFF assumes a decline in export revenues through 2010 with a subsequent increase in 2011 and 2012. The Board believes Hydro has been conservative in its planning and its projection of future export revenues given historical increases in extra-provincial revenues, the current export market and Hydro's competitive hydraulic power advantage. The Board however recognizes the level of export revenues depends on a number of factors including available water flow, market prices, and a proper balance between demand and supply. Conservative assumptions are, in the Board's view, an appropriate and prudent strategy given the nature and magnitude of the risks involved.

The Board accepts IFF MH 01-1 is a general indication of Hydro's long-term financial direction for decision-making purposes. The Board notes that the IFF does not reflect any future major generation projects within the planning period, nor the impact of the acquisition of Winnipeg Hydro, both of which may significantly impact the financial forecast and plans of Hydro. The Board will direct Hydro to file an updated IFF reflecting new generation in-service dates within the planning period, and the financial consequences of the integration of Winnipeg Hydro's operations by no later than December 31, 2003.

21.2 Financial Targets

The Board has previously stated a debt equity ratio of 85:15 is a reasonable short to medium term financial target and agrees with Hydro that a long-term target ratio of 75:25 is appropriate. The Board notes that the achievement of the 75:25 debt equity target should include a strategy for the reduction of the level of its debt.

The Board remains concerned with the current high level of debt and the additional risk posed to Hydro of incurring higher finance charges due to increases in interest rates and fluctuations in the US exchange rate on its US denominated debt. The Board is particularly concerned with the dramatic increase in long-term debt from $5.17 billion in 1997 to $6.43 billion in 2002, especially during a period of limited major capital expansions in generation or transmission. The Board encourages Hydro to consider appropriate debt minimization strategies. The Board notes the Corporate Strategic Plan includes a reference to reducing debt and improving equity to meet this target. Accordingly, the Board will direct Hydro to file a detailed debt management strategy with the Board by no later than December 31, 2003. This strategy should include the implications of major new generation contemplated within the planning period, and the related financing implications.

The Board is of the view that a gross interest coverage target ratio of 1.20 and the capital coverage target of funding the capital program (with the exception of new generation) from internally generated funds are appropriate financial targets which assist Hydro in achieving its long-term target of 75:25 debt equity ratio. However, the Board is also of the view that once the debt equity target has been reached, the current interest coverage target may, at that time, no longer be required or appropriate, and a lower target should then be considered.

21.3 Risks

In the Board's view a five-year drought represents the greatest threat to Hydro's financial position. It has been estimated that retained earnings reserves of approximately $1.3 billion may be required to withstand the financial impact of such an event. Although the actual amount might be mitigated somewhat by certain strategies, Hydro's net revenues are nevertheless subject to the vagaries of weather and water flows. Establishing an adequate reserve level is an appropriate strategy to mitigate the financial impact of a drought.

If Hydro experiences a drought, most opportunity sales will be foregone, thereby reducing export revenues. The Board generally supports Hydro's conservative approach to forecasting export revenues. The Board notes that although high export revenues have brought positive financial impacts, it has also increased the risk to Hydro. Continued high export revenues may permit Hydro to offset the need for rate increases in the future.

While there may be some risk of an export market collapse due to US legislation, regulatory changes or energy subsidies, amongst other things, there is also a probability of increased market prices, and therefore, increased export revenues. Export revenues on average over the last seven years have been 15% higher than forecast under the mean flow scenario. If this trend continues over the next few years, Hydro will achieve its targeted debt equity ratio earlier than forecasted and a retained earnings level in excess of $1.5 billion. According to Hydro this level of retained earnings should be sufficient to deal with identified risks. As another risk, the Board would agree that higher interest rates could have a modest negative impact on Hydro's financial position, as could higher inflation rate than forecast. Similarly, major system outages could negatively impact Hydro's finances.

21.4 Risk Analysis and Reserve Levels

The Board understands the difficulty of preparing a comprehensive quantitative analysis of all risks facing Hydro, as recommended by Mr. Todd. The Board believes, however, there is merit in quantifying specific reserve provisions required to cover the major contingencies Hydro faces. The specific amounts should be based on a process that identifies and quantifies at least the major risks at a high level. To do otherwise would be tantamount to establishing a reserve provision at an arbitrary amount. Defining specific reserve amounts for contingencies may also help prevent reserve provisions from being depleted for other purposes.

Although each risk has its own financial quantification, one cannot simply consider all risks together as additive, since many of the risks are inter-related. In reviewing risks, Hydro is urged to further examine their inter-relationships.

The Board believes that Hydro should develop a policy to identify a reserve provision amount and, in particular, to set the circumstances under which it can be drawn down or increased, keeping in mind the statutory limitations in *The Manitoba Hydro Act*. The Board expects that Hydro has most, if not all, of the required data in one form or another as part of its ongoing planning and risk management. The Board will therefore direct Hydro to prepare a document to quantify specific reserve provisions required to cover the major risks and contingencies faced by Hydro, and file that document with the Board by no later than December 31, 2003. A more disciplined approach to risk quantification can only be beneficial to the financial planning of

Hydro and assist the Board in its rate setting obligations, particularly with regard to the objective of determining an appropriate rate reserve level.

21.5 Capital Expenditures

Order 51/96 recommended that Hydro "stringently limit its capital expenditures where safety and reliability constraints allow and apply itself to reducing long-term debt with urgency." The Board remains concerned with the progressive growth in capital expenditures, and notes the dramatic increase in capital expenditures from $250 million in 1996 to $425 million in 2002. The Board reiterates its concerns expressed in Order 51/96.

The Board is particularly concerned with planned future capital expenditures that are justified primarily by export revenue opportunities. While very few projects are now justified exclusively for export, many projects nevertheless have a substantial export component. Hydro has indicated that certain future major capital projects will initially be for export purposes. The Board directs Hydro to appropriately identify and specifically account for all export-related capital expenditures in their capital forecasts. This information is required to ensure that export revenues are appropriately matched against the full costs of production and to ensure that Hydro's domestic ratepayers do not subsidize export market costs in the future.

Planning studies attracted substantial review in this hearing. Not only was the total amount spent of some $130 million of concern to the Board, but also the amount spent on particular projects (i.e., $34.1 million on Gull, $22.3 million on Wuskwatim). Hydro has agreed to pay for certain costs of the First Nations' participation in planning for new generation stations. Of concern to the Board is the very real likelihood of Hydro paying for what are, in essence, duplicate studies, by undertaking their own studies on aspects of new generating facilities and then paying for the First Nation partner to conduct a similar study. Given that such payments in 2002 are in the range of $1 million per month for the Wuskwatim generating station, and nearly $2 million per month for Gull, the Board urges Hydro to be diligent in how the ratepayers' monies are being spent and minimize such duplication.

21.6 Payments to the Province of Manitoba

Payments to the Province of Manitoba have increased dramatically, which impacts Hydro's revenue requirements. As many of the increases are legislatively enacted, Hydro has no choice but to make such payments. Nevertheless, such dramatic increases in payments have a negative effect on the ability of Hydro to achieve its financial targets, and may ultimately affect the level of rates paid for electricity. That having been said, the Board recognizes that dividend payments similar to the special export profit payments are not uncommon in publicly owned utilities.

Hydro does not intend to increase its sales rates as a result of the special export profit payment, or the increases in water rental rates or the debt guarantee fee. Hydro will be financing its payments to the Province of Manitoba. The costs of borrowing the $288 million for the special export profit payment over the next ten years is $276 million. Therefore, the total impact of that payment alone is $564 million over the next 10 years. Ultimately, future ratepayers will pay the financing costs. The Board encourages Hydro to pursue short-term financing options to pay down this debt expeditiously and reduce the impact of such charges to future domestic ratepayers.

21.7 Finance Expenses

The Board notes that a significant dollar value of transactions are conducted in US dollars including US extra-provincial sales, US sinking fund investment income and finance expenses. In addition, over $2.9 billion or 45% of the Corporation's debt is denominated in US currency, which exposes Hydro to risks related to the change in US exchange rate. The Board further notes that the exposure management program is in place to act as a hedge in protecting Hydro from the significant foreign currency risk related to the change in the US currency. As a result of the program, prior to the change in accounting policy, Hydro had reflected the balance of the US debt, and sinking fund at a designated US exchange rate, which has been significantly below the rates currently experienced. As a result of this policy, the debt of Hydro at March 31, 2001 was valued at approximately $1 billion less in the financial statements than it would have been if the year-end exchange rate had been used to translate the US denominated debt into Canadian dollar equivalent.

The Board notes that as a result of the accounting policy change, US denominated transactions and balances will better reflect the true economic costs and benefits and more clearly reflect the risks faced by Hydro to US denominated transactions and balances, which in the Board's view, are significant.

21.8 Operating Expenses

Although Hydro's operating and administration expenses appear reasonable, the Board encourages Hydro to continue to control these expenses through aggressive cost control initiatives and management of the labour force. The Board appreciates that some operating and administration expenses, particularly payments to the Province, are beyond Hydro's control. However, it remains necessary for Hydro to continue to be diligent in taking steps to control all such costs and improve efficiencies.

Corporate performance measures such as the operating and administration costs per customer or per kW.h targets are of great assistance in assessing the performance of Hydro's cost control initiatives compared to other utilities. The Board recommends Hydro aggressively pursue meeting its operating and administration costs per customer target while finding ways to increase productivity. The Board also encourages Hydro to continue to participate in benchmarking initiatives to help identify and implement further efficiencies and enhancements in its operations as compared to other utilities. Hydro should actively pursue all possible synergy savings in operating and administration expenses as a result of Hydro's recent acquisition of Winnipeg Hydro.

21.9 Transmission Tariffs

The jurisdiction of the Board over transmission tariffs is an area of concern to the Board and parties were requested to address this issue in their closing argument.

The MISO tariff does not apply to the Hydro transmission grid, but only outside the Province. Therefore, there is no provincial authority over the MISO tariff, and accordingly, no role for the Board.

The Board receives its jurisdiction and obligations for Hydro rates mainly from *The Crown Corporations Public Review and Accountability Act*. Rates for services provided by Hydro shall be approved by the Board, which rates for service means the provision of electrical power. Even though Hydro can issue its own tariff under s. 15 of *The Manitoba Hydro Act*, Hydro is still obligated to have such a tariff as a rate for service for the provision of electrical power approved by the Board. Whether the provision of power is bundled or unbundled between generation, transmission and distribution, the Board retains the jurisdiction to approve rates for service if offered in this province.

Accordingly, the Board will direct Hydro to make a separate application to the Board for approval of the Hydro Open Access Transmission Tariff. Hydro is ordered to file such an application by no later than June 30, 2003. Such an application should contain tariff and rate schedules, and a comprehensive explanation of the pricing and costs included in designing the rates.

21.10 Power Resources

Hydro stated that any periodic failure to meet base domestic plus firm export load is unacceptable. Base domestic load growth and firm export load growth are the primary drivers for new and additional power resources. Therefore a strategy to avoid brown-outs under all normal circumstances will result in substantial energy surpluses in most years. This surplus can then be sold as an opportunity sale on the export market.

If Hydro were to employ a median water flow scenario, instead of mean flow, in its energy forecasts, the amount currently available for export could be increased. By employing relatively conservative forecasting processes for supply and demand, Hydro will continue to enjoy more favourable financial results than forecast, except when droughts actually happen. From 1997 to 2001 there was an additional 10,000 GW.h of export energy due to hydraulic generation being above-median water supply, resulting in incremental annual revenues of approximately $200 million. Nevertheless, the Board considers it appropriate for Hydro to continue employing the conservative mean water flow scenario.

The Board notes the concerns expressed by Intervenors that Hydro may be paying less attention to creating competitive opportunities and developing energy conservation initiatives in the domestic market. While the Board encourages Hydro to pursue export markets and the corresponding revenue opportunities, Hydro's primary purpose continues to be the supply power adequate for the domestic needs of the Province.

The Board urges Hydro to explore ways to diversify and supplement its hydraulic generation capabilities by applying an appropriate mix of other forms of energy, including wind turbines, solar panels, ground source heat exchange, and hydrogen cells. Hydro should give particular consideration to exploring alternatives such as wind turbines for the four remaining diesel generation communities. Here, the back-up diesel power generator is already in place and an alternative energy supply may be justified on either an environmental or cost basis.

Hydro no longer supplies copies of its Power Resource Plan, citing confidentiality due to the increased competitive nature of electricity trading in the US. Should the Board be seized with a needs and justification hearing for major new generating stations, arrangements may need to be made to examine the Power Resource Plan.

21.11 Cost of Service Study

21.11.1 General

A cost of service study is one of the fundamental tools used by utilities in the overall rate design process. Much judgment is applied in completing a cost of service study. The results of a cost of service study are used in designing rates that are fair and equitable to customer classes. Generally, fairness is attained when revenues from each customer class approximates the net allocated costs of serving that class.

Hydro has made numerous changes to its proposed Cost of Service Study since it was last reviewed by the Board in Order 51/96. The Board will direct Hydro to file two cost of service studies; an actual cost of service study for the fiscal year ended March 31, 2003 by no later than September 30, 2003 and a prospective cost of service study for the fiscal year ending March 31, 2004 by no later than September 30, 2003. The following sections contain the Board's comments and directives with respect to changes proposed by Hydro, and requirements for the Cost of Service Studies to be filed with the Board in the future.

21.11.2 Winnipeg Hydro

Hydro has acknowledged that adjustments will be required to the proposed Cost of Service Study to accommodate the recent purchase of Winnipeg Hydro assets by Hydro. Hydro has stated it will have a better understanding of Winnipeg Hydro costs by late 2002. Achieving a precise understanding of detailed customer load and revenue cost information may take longer. Hydro did not rule out that methodological changes to the Cost of Service Study may be required. The

Board expects that the acquisition of Winnipeg Hydro may have a dramatic impact on the RCC's of the various customer classes. The Board also does not accept the methodology applied to Winnipeg Hydro matters in the March 2002 Cost of Service Study. The Board will therefore direct Hydro to treat Winnipeg Hydro customers in the same fashion as current Hydro customers in the March 2003 Actual Cost of Service Study and the March 31, 2004 prospective Cost of Service Study. It is important to know the impact of Winnipeg Hydro on the Cost of Service Study as soon as possible.

21.11.3 Allocation of Export Revenues

A major change to the Cost of Service Study methodology proposed by Hydro is to allocate net export revenues to customer classes on the basis of total allocated costs, being each class's share of generation, transmission and distribution costs.

The Cost of Service methodology approved in Order 51/96 allocates net export revenues to rate classes in proportion to class responsibility for generation and transmission costs. Distribution costs, of which a large percentage is allocated to residential customers, were not part of the allocation formula. It has long been argued by Hydro that it is primarily the generation and transmission assets that create the opportunity for export sales. Therefore, based on accepted cost causation principles, the benefits from export sales in the past were shared by the rate classes in proportion to each rate class' responsibility for generation and transmission costs.

In the public hearing related to Hydro's 1994 GRA, CAC/MSOS submitted that allocation of net export revenues on the basis of total cost responsibility (i.e., generation, transmission and distribution costs) would be more beneficial to the residential class. In 1994 Hydro opposed the CAC/MSOS cost of service methodology that Hydro now proposes in 2002. Hydro's position in 1994 was that export revenues are derived from generation and transmission capacity built to provide firm service to domestic loads, and since the costs of these facilities are allocated totally to domestic rate classes, it is proper to share the export revenues derived from this capacity in proportion to cost responsibility of such classes.

In Order 64/94, the Board stated at page 33, "…Hydro's method of allocating net export revenues is appropriate for Hydro's system, because it proceeds from the principle of cost responsibility rather than mere judgment." The Board further stated "… that it would be inappropriate to allocate any portion of export revenues as an offset to distribution costs within the central system or to costs in the Diesel Zone."

The Board has heard no new evidence at the current hearing to support or justify a departure from the principles of cost causation previously adopted for allocating net export revenues. Because export revenues arise from generation and transmission capacity, the Board believes that it continues to be appropriate to allocate the net export revenues derived from that capacity in proportion to class responsibility for generation and transmission costs.

In the Board's view, many direct and indirect costs related to export power sales are currently not included in Hydro's calculation of net export revenues. The Board notes that this matter was the subject of a recommendation in its March 31, 1988 Report to the Minister, at page 51 and 52, where the Board stated:

> "The Board recommends that revenues and costs related to export sales should be segregated in Hydro's accounting records. Costs include direct costs as well as indirect or allocated costs. The purpose of this segregation is to ensure that the Manitoba ratepayer is not subsidizing export sales.
>
> A possible method would be to treat export sales as a separate customer class in the Cost of Service Study. The result would not be used in designing rates for export sales because of the fact that such sales are open market negotiated sales. The only relevance to the resulting export class revenue/cost ratio would be to ensure that Manitoba customers are not allocated costs related to export."

This Board believes these comments remain appropriate today, and accordingly will direct Hydro to file an actual cost of service study for 2003 and a prospective cost of service study for 2004, that reflects:

(a) The creation of a Firm Export Class. This class should include long-term firm export sales and one-year firm export sales, with costs allocated on a fully embedded basis using a 2 CP allocation as employed for general service customers; and

(b) The creation of an Opportunity Export Class. This class should allocate costs using a similar basis to the domestic interruptible GSL customer class.

These Cost of Service Studies should include the impact of allocating net export revenues determined in accordance with the above directives on the basis of transmission and generation costs. Once these submissions have been filed, the allocation methodologies may require further consideration by the Board.

21.11.4 Functional Changes to the Cost of Service Study

Previously, all transmission lines and stations, including HVDC facilities, were included in the transmission function. In the March 2002 Cost of Service Study, all HVDC assets, with the exception of the Dorsey Converter station, were assigned to the generation function. The Board accepts this methodology and Hydro's reasoning that the primary function of the HVDC facilities is to move energy from the remote generation sites into the backbone transmission system and therefore serve as an extension of the generating facilities.

The Board, however, has some concerns about the exclusion of the Dorsey Converter Station from the HVDC assets assigned to the generation function. While the assignment of the Dorsey Station to the transmission function has relatively minor impacts to revenue cost coverage ratios under current operating circumstances, the Board has concerns this may change as additional generation and transmission facilities are constructed in the future. The Board will expect Hydro to re-evaluate the continued appropriateness of this treatment in the future.

Hydro has also assigned the AC transmission lines that provide power to the northern converter stations as generation. The Board accepts this methodology since these lines are required to bring generated power to the HVDC converter stations in the north.

The Board also accepts Hydro's proposed assignment of only those transmission facilities, which would be recognized for inclusion in Hydro's Transmission Tariff, to the transmission function. Radial transmission facilities, including those with voltages greater than 100 kV, are included in the sub-transmission function.

The Board accepts Hydro's creation of a new ancillary services function necessary to support the transmission of capacity and energy to the load.

21.11.5 Classification Changes to the Cost of Service Study

Hydro's November 2001 Prospective Cost of Service Study used marginal costing to classify generation costs to energy and demand. For reasons of commercial sensitivity, Hydro was unable to provide information supporting its determination of relative marginal costs. Hydro therefore proposed to revert back to the previous methodology. The Board accepts this approach given the commercial sensitivity of marginal cost information.

In the March 2002 revised Cost of Service Study, Hydro returned to the pre 2001 approach and classified total generation and transmission costs (including ancillary services) on the basis of the system load factor. However, in the March 2002 approach, transmission and ancillary services are classified as 100% demand related. The balance of demand related costs are then assigned to generation. This results in a demand to energy classification division of transmission and generation costs of approximately 36% to 64% respectively. If, however, transmission costs are classified as 100% demand and the system load factor is applied to generation costs only, this approach would result in a demand to energy classification division of generation and transmission costs of approximately 48% to 52%.

The Board accepts the classification of transmission assets at 100% demand related, however, the methodology used to classify generation costs is of concern to the Board. Hydro has stated it is prepared to undertake a further review with respect to the appropriate classification of generation costs. The Board will therefore direct Hydro to complete this review of generation cost classification methodologies by December 31, 2003. This review should critically examine the impacts of the various methods of classifying generation costs, and describe how such classification methods would impact the overall rate design process in terms of setting demand and energy charges.

The Board accepts Hydro's proposed methodology with respect to classifying ancillary services as 100% demand.

21.11.6 Allocation Changes to the Cost of Service Study

The process of allocation takes functionalized and classified costs and assigns the costs to the various customer rate classes and subclasses. Hydro has proposed a number of changes in cost allocation methodologies.

In the November 2001 allocation methodology, energy related generation costs were allocated to each customer class according to the class contribution of the highest integrated 50 hour load during the winter and summer seasons. This treatment was changed in the March 2002 where energy related costs of generation were allocated to customer classes on the basis of their share of overall annual energy requirements, the same methodology used in the Cost of Service Study approved in Order 51/96.

The March 2002 Cost of Service Study proposed to allocate generation demand costs on the basis of each class of customer's share of the average of the top 50 coincident load hours during the months of June, July and August and the top 50 coincident load hours during the months of December, January and February (2 CP Methodology). Hydro stated this treatment recognized the value of energy and capacity during the summer and winter seasons. Although the domestic peak continues to occur in winter, loads can be as high as other times of the year, particularly the summer months. With a strong export market during the summer months, transmission and generation assets can be fully utilized at the time of summer peaks. Based on this reasoning, the Board accepts Hydro's methodology to allocate demand related costs of generation on the basis of the 2 CP method.

Hydro has proposed to allocate transmission and ancillary services related costs to customer classes on the basis of the 12 CP method with each month being given equal weight. Hydro argued that this approach is consistent with the treatment in the Transmission Tariff in which transmission pricing in the open access market is based on the 12 CP method. The Board is of the view that allocation of costs on a 2 CP basis would be a stronger correlation to cost causation. Participation in MISO does not oblige Hydro to adopt similar pricing structures for the domestic market. The Board therefore rejects the allocation of transmission and ancillary service costs on the basis of the 12 CP and directs Hydro to allocate these costs on a 2 CP basis similar to that used for the generation demand costs.

The Board also supports the continued practice to allocating DSM costs to the customer classes that receive the benefit.

21.11.7 Future Cost of Service Studies

Given the above comments, the Board has fundamental concerns with both the November and March Cost of Service Study submissions. Therefore, the Board will direct Hydro to file an actual cost of service study for year ending March 31, 2003 by September 30, 2003 and a prospective cost of service study for the fiscal year ending March 31, 2004 by September 30, 2003 reflecting the following:

(a) The former Winnipeg Hydro revenues and costs are appropriately assigned to the various customer classes in the same fashion as current Hydro customers.

(b) Net export revenues are allocated on the basis of generation and transmission costs only in accordance with Order 51/96.

(c) Transmission costs, including Dorsey, are classified as 100% demand.

(d) Transmission and ancillary services costs are allocated on the basis of the 2 CP.

(e) Generation demand costs are allocated on the basis of the 2 CP.

(f) Energy related costs of generation are allocated on the basis of class annual energy (Non-Coincident Peak).

(g) HVDC costs (other than Dorsey) are functionalized as generation.

(h) Only transmission facilities recognized for inclusion in Hydro's Transmission Tariff are included in the transmission function.

(i) The creation of a Firm Export Class. This class should include long-term firm export sales and one-year firm export sales, with costs allocated on a fully embedded basis using a 2 CP allocation as employed for general service customers; and

(j) The creation of an Opportunity Export Class. This class should allocate costs using a similar basis to the domestic interruptible GSL customer class.

21.12 Rate Design

21.12.1 General

Although Hydro did not apply for any changes in rate design, the Board and the Intervenors considered the issues of rate design to be of considerable importance in this status update filing. As part of the Board's review as to whether the rates charged remain just and reasonable, the Board not only examined the overall revenue requirement, but also the cost of service methodology, and the rate structure itself.

The Board is disappointed with the inaction of Hydro to comply with the spirit of Order 51/96 with regard to undertaking a study and reporting to the Board by no later than the next GRA to develop a comprehensive rate design policy. More than six years have elapsed since that directive was issued, and Hydro stated at this hearing that it has no intention of preparing such a study in the near future. Such inaction is a disservice to the many Hydro customers, particularly those who might benefit from such a comprehensive rate design policy.

Having reviewed rate design issues as part of this status update, the Board believes that certain rates require adjustment.

21.12.2 Rates

After examining the overall revenue requirement of Hydro, the Board finds that there is no need for an overall rate adjustment for all customer classes. However, the Board is of the view that rates for certain customer classes should be adjusted.

Much time was spent at the hearing reviewing the Cost of Service Study. A revenue to cost ratio of 1.0 indicates that costs allocated to a customer class equal the revenues earned from that customer class. While unity may be the desired goal, Order 51/96 sets a zone of reasonableness target at 0.95 to 1.05 for revenue to cost coverage ratios. The Board is of the view that this zone of reasonableness of 0.95 to 1.05 continues to be an appropriate target for rate setting purposes.

As demonstrated in the table in Section 17.8.5, certain customer classes and subclasses have consistently remained outside of this zone of reasonableness for long periods of time, in some cases more than 10 years. Therefore, the Board is convinced that directional rate adjustments are appropriate now to address these inequities. Accordingly, the Board will order a 1% decrease in rates for GSS customers and a 2% decrease in rates for GSL customers in subclasses greater than 30 kV. Such rate decreases are to be effective April 1, 2003. The Board will direct Hydro to file new rate schedules for Board approval reflecting these rate adjustments.

The Board will also eliminate the winter ratchet over the next two years, which will reduce revenues to Hydro by approximately $3 to 4 million. The Board understands that this change will likely bring the GSM class and GSL subclass less than 30 kV closer to unity. Therefore, no further rate adjustment will be ordered for the GSM or GSL less than 30 kV subclass at this time.

The Board is confident that these rate adjustments will not impact the overall financial strength of Hydro, or its ability to achieve its financial targets.

21.12.3 Inverted Rates and Rate Structure

The declining block structure is largely the result of the historical circumstances of electrification throughout the Province and the construction of major generating plants on the Northern rivers. While the Board is not prepared at this time to support an inverted rate structure, the Board accepts that certain concepts of an inverted rate structure for residential customers may have merit for consideration in the future. The Board compliments both Mr. Lazar and Hydro for preparing thoughtful evidence on this matter and raising interesting new approaches. The Board believes that more study is required before an inverted rate structure can be considered for any customer class. The Board will direct Hydro to prepare a study on the merits of an inverted rate structure across all rate classes including transition and implementation issues. As part of this study, Hydro should evaluate the impact of an inverted rate structure on electric heat customers and residential customers with higher than average loads. This study should be filed with the Board by no later than December 31, 2003.

While the issue of inverted rates was largely confined to residential rates, the Board investigated demand and energy charges levied on larger General Service customers as part of the overall rate design. In the Board's opinion, some of Hydro's demand charges are in the mid to high range as compared to other jurisdictions in Canada, while the energy charges are amongst the lowest in Canada.

The Board is of the belief a lower demand charge and higher energy charge may serve as an impetus to further conservation of electricity since the users may become more aware of their consumption and hence, may attempt to minimize usage. Accordingly, the Board will direct Hydro to prepare a study on the impact of decreasing the demand charge and increasing the tail block of the energy charge and include recommendations and a timetable for possible implementation. The study should be filed with the Board by no later than December 31, 2003.

21.12.4 Winter Ratchet and Limited Use Billing Demand

In the 1996 GRA, Hydro sought to eliminate the winter ratchet with the implementation of seasonal rates. However, with little actual evidence and no customer consultation, the Board did not support the implementation of seasonal rates, and directed further study by Hydro. Since then, the LUBD program was introduced to alleviate some irritants posed by the winter ratchet. The Board is of the view that winter ratchet continues to pose problems for customers unable to benefit from the LUBD program.

The traditional rationale for the winter ratchet is that additional winter capacity to meet peak demand requires significant and costly capital expansions. The winter ratchet is designed to recover capacity costs incurred to meet this peak demand. The current system load runs nearly at capacity throughout the year as any additional capacity beyond domestic use is sold on the export market. Therefore, the Board finds that the use of the winter ratchet is not valid in the current circumstances. Accordingly, the Board will order Hydro to phase out the winter ratchet in two steps. On April 1, 2003, the winter ratchet is to be decreased to 70% of the maximum previous winter demand measured in December 2002, and January and February 2003. On April 1, 2004, the winter ratchet is to be eliminated. The Board will order Hydro to file the resulting rate schedules, for Board approval, prior to the above dates.

The Board will order the LUBD be eliminated on April 1, 2004. All LUBD customers will then revert to the billing rate of their appropriate class. Until April 1, 2004 the LUBD rate option will be considered a temporary rate offering. The Board also expects Hydro to inform all LUBD customers of this decision and its implication. The Board will grant final approval of Order 118/02 which extended the LUBD rate option on an interim ex parte basis.

21.12.5 Time of Use Rates

In Order 51/96 the Board directed Hydro to prepare a comprehensive rate policy including time of use rates which remains outstanding. The Board heard testimony that Hydro continues to install specialized metering equipment for certain general service customers with time of use capability. Accordingly, the Board considers it important to proceed with the development of time of use rates and directs Hydro to prepare a study, including a timetable and a plan for implementation, for a time of use rate program. Such study should also consider time of use rates for general service classes based on a seasonal, weekly, daily and hourly basis, including an evaluation of each alternative. The study should be filed with the Board by no later than December 31, 2003.

21.12.6 Diesel Rates

Any determination of whether rates are just and reasonable must include an examination of rates charged to those customers serviced by Hydro's diesel generation. The Board cannot make a determination on which customer should be included in a specific rate class of government versus non-government or whether a customer has sufficient resources to pay the bill, or funding formulas are appropriate.

During the hearing, Hydro stated it would be filing a separate application for diesel rates in December 2002. Such an application has now been filed and the Board will consider diesel rate issues at a future public hearing to review this filing.

21.12.7 Curtailable Rates

Hydro applied for a new CRP which included only minor variations from the existing curtailable service program. The rationale for curtailments has changed and, as stated by Hydro witnesses, the number of curtailments will likely decrease sharply. However, the Board is reasonably satisfied with the rationale used in the calculation of the Reference Discount.

Hydro has applied for the CRP to be a temporary program with an expiry date of November 30, 2003, given the unknown impact of MISO's requirement and the value of reserves. In the interest of rate stability, the Board will approve the CRP on a permanent basis.

21.12.8 Surplus Energy Program and Interim Ex Parte Orders

The Board will approve, on a final basis, all interim ex parte Orders relating to the DFH, ISE, SEP and CSP programs as attached in Appendix E.

21.12.9 Demand Side Management - Energy Conservation

The Board acknowledges that Hydro's initiatives on DSM since 1989 have achieved approximately 50% of targets set for 2012 of 356 MW and 1,272 GW.h. However, it is the Board's view the new DSM programs may not be effective for achieving DSM targets for 2012.

In this period of potential generation expansion the Board is concerned that Hydro may reduce efforts for DSM. It would appear that other utilities are more proactive in pursuing energy conservation measures. A program target for energy use reduction of 3% does not seem to be sufficiently aggressive.

The Board is of the view that, at present, Hydro provides few incentives for either residential or general service customer energy conservation. Financial incentives such as a movement toward lower demand and higher energy charges could encourage more efficient energy usage. Greater energy conservation within Manitoba opens the door for increased power exports with good financial returns. The Board views this as a positive process, particularly if the exported energy displaces coal or other greenhouse gas producing generation within other jurisdictions.

Therefore, the Board directs Hydro to re-examine the current level of DSM programs and pricing strategies to encourage conservation and develop a program with more aggressive targets to be filed with the Board by December 31, 2003.

Wind power offers potential fuel consumption reductions where the primary source of power is coal, natural gas, propane, or diesel. It can be a lower cost supplier of electricity where a primary fuel-based generator already exists and is available as a full back-up when the wind velocities are too low. The Board directs Hydro to consider the use of wind power in remote diesel electric communities where energy costs are high and file a report with the Board by December 31, 2003.

21.12.10 Future Regulation

The Board recognizes the many parties who expressed frustration with Hydro's absence from public review for over six years. The Board reiterates the statement made in Order 208/02 that Hydro establish a more regular schedule, not exceeding three years, for periodic rate reviews. This regular schedule should improve the efficiency, effectiveness and timeliness of the regulatory process, even if no rate changes are requested. Subject to other specific directives contained herein, the Board will approve Hydro's existing rate schedules to be in effect until March 31, 2006 or until otherwise amended by a further Order of the Board. The Board will direct Hydro to file a GRA for rates to be effective April 1, 2006 whether or not rate adjustments are sought. This directive does not preclude Hydro from filing applications for rate adjustments prior to this date.

22.0 It Is Therefore Recommended That:

1. Hydro limit its capital expenditures not related to new major generation and transmission, where safety and reliability constraints allow, and apply itself to reducing its long-term debt.

2. Hydro be diligent in ensuring it does not pay for duplicate planning studies for new generation projects.

3. Hydro pursue short-term financing options to expeditiously pay down the debt incurred for the special export profit payment to the Province of Manitoba, and thereby reduce the impact of such financing charges to future domestic ratepayers.

4. In respect of operating and administration expenses:

   (a) Hydro pursue with vigour meeting the operating and administration cost per customer target of $600 by increasing productivity.

   (b) Hydro continue to participate in benchmarking initiatives.

   (c) Hydro actively pursue all possible synergy savings in operating and administrative expenses as a result of its recent acquisition of Winnipeg Hydro.

5. Hydro consider ways to diversify and supplement its hydraulic generation with an appropriate mix of other forms of energy, including wind turbines, solar panels, ground source heat exchange and hydrogen cells.

23.0 It Is Therefore Ordered That:

1. The interim ex parte Orders listed in Appendix E of this Order BE AND ARE HEREBY CONFIRMED AS FINAL.

2. The Curtailable Rates Program as applied for by Hydro BE AND IS HEREBY APPROVED.

3. Hydro file for Board approval a revised schedule of rates to be effective April 1, 2003 including revenue impacts that reflect:
   (a) A 1% rate decrease for General Service Small customers;
   (b) A 2% rate decrease for General Service Large customers in subclasses greater than 30 kV; and
   (c) A decrease in the winter ratchet to 70% and the subsequent elimination of the winter ratchet effective April 1, 2004.

4. Hydro eliminate the Limited Use Billing Demand Rate option on April 1, 2004 and inform all affected customers of the changes to the winter ratchet and the Limited Use Billing Demand Rate option.

5. Hydro file an application with the Board by no later than June 30, 2003, for approval of Hydro's Open Access Transmission Tariff.

6. Hydro file the following information with the Board by no later than December 31, 2003:
   (a) An updated Integrated Financial Forecast reflecting the integration of Winnipeg Hydro and the in-service dates of all new generation within the eleven-year planning period;
   (b) A detailed debt management strategy;
   (c) A study to quantify specific reserve provisions required to cover the major risks and contingencies faced by Hydro;
   (d) A study on the merits of implementing an inverted rate structure for all customer classes;
   (e) A study on the impact of decreasing the demand charge and increasing the tail block of the energy charge;

(f) A study which considers time of use rates for GS classes based on a seasonable, weekly, daily, and hourly basis;

(g) A review of generation cost classification methodology options;

(h) Re-examine the current level of DSM programs and pricing strategies to encourage conservation, develop a program with more aggressive targets, and report to the Board; and

(i) Consider the use of wind power in remote diesel electric communities and file a report with the Board.

7. Hydro's proposed Cost of Service Study dated March 2002, which includes a number of methodology changes including allocating net export revenues to customer classes on the basis of total allocated costs BE AND IS HEREBY DENIED.

8. Hydro file an actual cost of service study for the year ended March 31, 2003 by no later than September 30, 2003 and a prospective cost of service study for the year ended March 31, 2004 by no later than September 30, 2003 which reflects the following:

(a) The former Winnipeg Hydro revenues and costs are appropriately assigned to the various customer classes in the same fashion as current Hydro customers.

(b) Net export revenues are allocated on the basis of generation and transmission costs only in accordance with Order 51/96.

(c) The creation of a Firm Export Class. This class should include long-term firm export sales and one-year firm export sales, with costs allocated on a fully embedded basis using a 2 CP allocation as is proposed for general service customers; and

(d) The creation of an Opportunity Export Class. This class should allocate costs using a similar basis to the domestic interruptible GSL customer class.

(e) Transmission costs, including Dorsey are classified as 100% demand.

(f) Transmission and ancillary services costs are allocated on the basis of the 2 CP method.

(g) Generation demand costs are allocated on the basis of the 2 CP method.

(h) Energy related generation costs are allocated to customer classes based on their share of the overall annual energy requirements (Non-Coincident Peak).

(i) HVDC costs (other than Dorsey) are functionalized as generation.

(j) Only transmission facilities recognized for inclusion in Hydro's Transmission Tariff are included in the transmission function.

9. Hydro appropriately identify and specifically account for all export-related capital expenditures in their capital forecasts to ensure that export revenues are appropriately matched against the full costs of production.

10. Hydro establish a more regular schedule for periodic rate reviews, not exceeding three years between hearings.

11. Subject to other specific rate directives contained herein, Hydro's existing rate schedules BE AND ARE HEREBY CONFIRMED, to be in effect until March 31, 2006, or until otherwise amended by a further Order of the Board.

12. Hydro file a General Rate Application for rates to be effective no later than April 1, 2006.

Executive Summary

Manitoba Hydro's (MH, the Corporation or the Utility) 2008/09 General Rate Application (GRA) was heard by the Public Utilities Board (Board) in the spring of 2008, with Board Order 90/08 released on June 30, 2008 to take effect July 1.

The Board further advised that Order 90/08 would be followed by another Order, one that would provide further direction on a number of other significant matters, and, as well, provide necessary background information and detailed rationale for the rate changes provided by Order 90/08.

Order 90/08 provided certain rate and other directions to the Corporation, as indicated elsewhere in this Order. Order 90/08 is available through the Board's office or by viewing its website, www.pub.gov.mb.ca.

With respect to "further direction", this Order contains various directives to provide new and revised information to the Board in respect of MH's:

- Integrated Financial Forecasts;
- Capital Expenditure Forecasts;
- Load Forecast and Power Resource Plan;
- Export Program;
- International Financial Reporting Standards Implementation;
- Benchmarking Study of Key Performance Metrics;
- Asset Condition Assessment Study;
- Terms of Reference for a Review of MH's Capital Program;
- Quantified Risk Analysis;
- Demand Side Management ("Power Smart" program enhancements);
- Green House Gas Reduction Strategy;
- Low-Income Programs, including a Bill Assistance Program;
- Cost of Service Study (COSS) Revisions;
- Rate Design Revisions;
- MH Diesel Rate Zone; and
- Energy Intensive Industry Rate Proposal.

Executive Summary

Detailed directives and recommendations are found in the last sections of this Order.

For all the reasons referred to in this Order and Order 90/08, the Board approved a 5% across-the-board rate increase as of July 1, 2008 that was larger than the Corporation sought, and, as well, indicated that a further 4% increase may be granted as of April 1, 2009 following the Board's review of additional information requested in this Order. As well, the Board accepted MH's forecast that its net income for the fiscal year 2007/08 will exceed $300 million, and that water conditions into fiscal 2008/09 were excellent, suggesting that another reasonably good net income result may be expected for fiscal 2008/09.

Order 90/08 also advised of the Board's concern with the scale of capital expenditures and new debt now planned over the next 15 years. There is a risk that the Corporation may not be able to meet domestic and export requirements and commitments without having to resort to high-priced imported power or other higher-cost generation in years of lower than median water conditions. The risk of lower than median water conditions, (including a drought), creates a financial risk. The other financial risks include the potential for future interest rate increases, currency fluctuations, capital cost escalations, new accounting standards (IFRS) and other operational factors, some or all of which may well challenge the Corporation's future financial strength.

The Board will direct MH to propose to the Board by January 15, 2009 terms of reference for a regulatory review of the impact that MH's planned Capital program may have on consumer rates. The Board will also direct MH to quantify its risks in an effort to determine the appropriateness of the current financial stability targets.

Executive Summary

The Board also expresses concern with the Corporation's withholding of information related to its export transactions and projections, for stated confidentiality reasons, as that withholding made it difficult if not impossible for the Board to arrive at findings with respect to such matters as to what constitutes the Corporation's marginal cost rate, a final determination of the rules to govern the allocation of costs and revenues to customer classes, the weight to be given to marginal and environmental factors in future differentiation of customer class rates, and, perhaps most importantly, the likelihood of profitability with respect to its export commitments and the risk that these commitments will lead to years of either additional imports of power or thermal generation to avoid supply shortfalls. Accordingly, the Board has requested additional information related to MH's export forecasts.

In this Order, the Board notes that there are approximately 100,000 low-income households that are customers of MH (many, also being customers of Centra Gas), and the particular affordability pressures on these households arising from energy price increases (gasoline, diesel, natural gas and, though much more modest, electricity).

The Board has recently approved issuance of a single bill for consumers of electricity and natural gas and provided MH an ability to maintain natural gas and electricity services, when financial delinquency conditions exist. These efforts avoid disconnections through the availability of an electricity load-limiter and will assist with the health and safety of consumers through the coming winter. However, the Board seeks further actions by the Corporation to address the varied problems of low-income households, problems exacerbated by rising energy costs.

Accordingly, by this Order the Board directs MH to increase its efforts to conserve domestic energy through far more aggressive DSM measures, including those particularly targeted at low-income households lacking the means to invest in energy efficiency measures without assistance from the Corporation.

The reduced consumption benefits expected to arise out of more successful DSM programs will assist low-income households in meeting their utility bills. It will also provide the Corporation with a higher level of supply security to meet future demand requirements.

There is a risk that if natural gas customers move in any significant way to electricity as the sole or supplementary space-heating source for their residences, (a growing risk given recent natural gas commodity price increases and volatility), MH will have less energy to export and may have to import power in some years to meet its commitments. MH's low rates for all of its customers, excluding "government accounts" in the diesel zone, are maintainable in part due to export profits.

Finally, herein, the Board suggests to government that it consider establishing a separate entity to manage the Corporation's DSM and low-income initiatives. The Board concludes that MH's full energies and focus should be placed on the effective implementation of its long-term expansion plans, towards meeting the demand for electricity and natural gas. The Board can envision MH establishing aggressive goals for the reduction of domestic energy consumption for such a new entity to target, together with providing funding to meet those targets. MH will benefit by being able to export the energy that is conserved.

1.0 Overview

1.1 History

Manitoba Hydro's last General Rate Application (GRA) was held in the spring of 2004, following a drought that contributed to a record loss of $428 million for the Corporation's electric operations. That 2004 GRA led to Board Orders 101/04 and 143/04, and those Orders approved a 5% average rate increase, effective August 1, 2004, and two additional average rate increases of 2.25% each, to be effective April 1, 2005 and October 1, 2005 – the latter two increases conditional on MH filing additional information and justification.

Subsequently, by Order 34/05 the Board confirmed the first of the two conditional 2.25% average rate increases, the first one taking effect April 1, 2005. However, due to a reported "dramatic" rebound in water conditions following the drought that contributed to rate increases in Order 101/04, and a favourable financial forecast for MH's fiscal year 2005/06, the Board was advised by MH (on July 5, 2005) that the Corporation would not seek the second conditionally approved rate increase, tentatively scheduled for October 1, 2005.

Water conditions ebb and flow, and subsequently, due to a return to poor water conditions during most of MH's fiscal 2006/07 (not anticipated by MH when it decided to forego the last of the two conditional rate increases), MH applied to the Board to reinstate that foregone average rate increase of 2.25%. After a thorough review of information submitted by MH, and by way of Order 21/07, the Board granted MH's application, effective March 1, 2007, on an interim basis. Final approval of that rate increase was later sought by MH as part of its 2008 GRA, and provided by the Board by way of recent Order 90/08.

1.2 2008 General Rate Application

In the summer of 2007, and pursuant to *The Public Utilities Board Act* and *The Crown Corporation Public Review* and *Accountability Act*, MH applied to the Board for the following:

a) Approval of rate schedules incorporating an across the board 2.9% increase in General Consumers' rates effective April 1, 2008 (with the exception of Area & Roadway Lighting which would receive a 1% increase);

b) Final approval of General Consumers' interim rates approved in Order 21/07 effective March 1, 2007;

c) Surplus Energy Program: immediate interim approval to extend the program (currently set to expire October 31, 2007) to October 31, 2008 together with final approval to extend the program to March 31, 2013;

d) Final approval of all Surplus Energy Program (SEP) interim rate orders as set out in Appendix 10.6 of the GRA;

e) Approval of modifications to the Curtailable Rate Program (CRP) as discussed in Tab 10, Section 10.2 of the Application, and final approval of all interim Curtailable Rate Program orders as set out in Appendix 10.6;

f) Final approval of changes to the Limited Use of Billing Demand Rate (LUBD) as set out in Appendix 10.6;

g) Contingent on final execution of the settlement agreement between Indian and Northern Affairs Canada (INAC), Manitoba Keewatinook Ininew Okimowin (MKO) and Manitoba Hydro, approval of interim *ex parte* Orders related to electricity service in the Diesel Rate Zone as set out in Appendix 10.6; and

h) Approval of a new General Service Large rate for new or expanding loads as set out in Tab 10, Section 10.3 of the GRA.

By Order 90/08 and following a public hearing of MH's GRA, the Board established an across-the-board rate increase of 5% effective July 1, 2008 for all MH customers, except for Area and Roadway Lighting customers, whose rates are not to change.

In addition, the Board approved:

a) A further conditional across-the-board general rate increase of 4%, with the exception of Area and Roadway Lighting customers (for whom rates are again not to increase), provisionally to take effect April 1, 2009 (subject to the Board's further review, that, depending on developments, could result in the Board increasing or decreasing the 4% increase conditionally approved);

b) An increase in the Basic Monthly Charge (BMC) for all customers of 5%, as of both July 1, 2008 and April 1, 2009;

c) As indicated above, finalization of Order 21/07 which established an interim rate increase of 2.25% on March 1, 2007;

d) A modest introduction of inverted rates for the "residential" class (SGS), establishing a precedent and indicating an intention to widen the differential in the future;

e) As requested by MH, extension of the Surplus Energy Program (SEP), although only to October 31, 2008 ahead of conclusions yet to be reached and a possible further extension to follow this Order;

f) Modifications to the Curtailable Rate Program, as proposed by MH;

1.0 Overview

g) Changes to the Limited Use of Billing Demand Rate, as proposed by MH; and

h) Final approval for various interim SEP Orders through to the date of the close of the hearing that led to Order 90/08.

Order 90/08 was issued on June 30, 2008, and also indicated that final approval of several Interim *Ex-Parte* Orders related to electricity service in the Diesel Rate Zone would be deferred until final execution of a Settlement Agreement between INAC, MKO and MH had occurred.

The Order also advised MH to re-file, "with any adjustments it may deem appropriate, a revised proposal for a new industrial rate for new and expanding industrial load".

Although the Corporation had sought a 2.9% across-the-board increase, excepting for a proposed 1% increase for Area and Roadway Lighting customers, and had indicated a need for further 2.9% across-the-board increases for each year through to 2017/18, the Board concluded that higher increases were required, at least for 2008 and 2009.

In Order 90/08, the Board noted:

> "With MH's new export and construction commitments and plans, and with the increased risk that MH's Manitoba load forecasts may prove low given the large increase in the price of natural gas over the past year (yet to be fully reflected in natural gas bills), and providing the risk of energy switching, the Board is also concerned with the risk associated with advancing major new generation and transmission projects with industrial rates well below marginal cost."

And,

> "While the Board is now providing a 5% increase for 2008 and the prospect for a further 4% April 1, 2009, the latter subject to reconsideration following receipt and review of additional information, the electricity rate increases now set and contemplated pale in comparison to the increases being implemented or planned by other Canadian electricity utilities, and the cost increases now being experienced by consumers, businesses, institutions and governments with respect to other energy sources. "

And,

> "Notwithstanding the Board's appreciation of the negative implications of rate increases for MH's customers, and the Board's particular and on-going concern for low-income households, particularly, in this case, those relying on electricity for space heating, the Board will provide MH with a greater increase than the Corporation sought. This, because of a combination of concerns briefly cited below (to be) elaborate(d) on in more detail in a subsequent Order:

a) In its application, MH advised that its proposed series of 2.9% increases were required to maintain progress towards the eventual attainment of the Corporation's financial targets, primarily the achievement of the long-sought but not achieved target debt to equity ratio of 75:25. MH projected that notwithstanding its forecasts of annual rate increases and the assumption of continuing success with export markets, and taking into account forecast net income for 2007/09 to achieve or exceed $300 million, it still did not expect to achieve the debt:equity financial target of 75:25 by 2017/18 (let alone the current or previous earlier target dates);

b) MH's plans for capital expenditures may involve the expenditure of $18 billion or more over the next 15 years, expenditures predicated in part on what may or may not be overly optimistic export prices – this level of capital expenditure will result in significantly increased debt levels, export commitments and general business risks;

c) MH's reports and evidence of hyper-inflation with respect to construction and commodity costs, which are driving up the Utility's projected costs for new generation and transmission projects and have lowered its estimates of the return to be expected for the first of its new generation projects (Wuskwatim), a project that will likely be followed by further major construction (Pointe du Bois, Bipole III, and the Keeyask and Conawapa generation stations);

1.0 Overview

d) While the Board shares some Intervener concerns as to an apparent acceleration of MH's OM&A costs (Operating, Maintenance and Administration), which MH attributes to labour shortages as well as increased needs for system maintenance, (both factors cited to be beyond the direct control of the Utility), the Board does not have enough information on whether current and forecast OM&A expenditures are fully supported, since no formal and in-depth benchmarking has yet been undertaken;

e) The approaching adoption of International Financial Reporting Standards (IFRS), which will form the new Canadian Generally Accepted Accounting Principles (GAAP), with potentially materially significant and negative impacts for the Corporation's current forecasts of annual net income results through 2017/18;

f) There has been a significant increase in the value of the Canadian dollar relative to American currency, and it has had the effect of reducing the value of electricity exports as expressed in Canadian dollars. The Canadian dollar has climbed from just above 60 cents U.S. dollar (USD) to near parity with the U.S. currency. With MISO imports (MH's exports) priced in USD, this has affected MH's export revenues. While MH forecasts the Canadian dollar falling back about 15 cents from its current level, the Board is not confident with that forecast, and if near parity remains MH's export price forecasts are in jeopardy;

g) There appears to be a growing disconnect between electricity prices obtained from American markets and natural gas prices (in the past, when natural gas prices rose, the assumption and general experience was that MH's export prices rose as well); and

h) Continuing business risks related to interest rates (now at recent historic lows), the risk of further currency fluctuations, drought, inflation, market access problems, and other concerns: "

"Interest rates are at very low levels in both an absolute and relative to inflation sense – the current prime rate of the Bank of Canada is approximately only one percentage point higher than the current national rate of inflation – and with hyper-inflation present with respect to commodities (including energy) and processed products such as chemicals, steel and concrete, the Board is concerned that interest rates will increase at some point during MH's expansion phase, placing increased pressure on the cost of the Corporation's operations."

1.0 Overview

And,

> "MH has benefited from 12 of the last 16 years being of above or near median water flows; statistically, poorer water conditions can be expected to occur at some point in the future and a drought, which has been experienced regularly through the Corporation's history, could have a devastating impact on MH's financial situation, as it recently did in fiscal 2003/04."

And,

> "MH's export market is primarily American utilities within the MISO market, and transmission lines on both sides of the border are required to transport the power to MH's export customers and carry power back to Manitoba when imports are required, and there are risks involved with reliance on a significantly predominant market. While a national east-west grid remains a worthy objective, there is no present indication that MH's Canadian provincial customer list, particularly from a volume perspective, can be assured to strongly develop."

The Board concluded its overview of the Corporation's risks by stating in Order 90/08 that it "is focused on the risks that lie ahead and determined to ensure as reasonably as possible that MH has the financial strength to meet the risks".

> "The rate changes and comments of present and future risks associated with this Order should not be perceived as a challenge to the perspective that MH remains a tremendous asset for Manitoba, and that the Corporation continues to have and represent large growth opportunities. Even with the rate increases announced and forecast herein, Manitobans should continue to benefit from some of the lowest electricity rates in North America.
>
> The Board also finds it important to recognize a present and growing disconnect between relatively stable and low electricity rates (set by a regulatory body with particular attention to historic costs) and other competing energy prices, the latter set by largely unregulated market forces little affected by the actual cost of production and distribution.
>
> With respect to MH, while the costs of generation, transmission and distribution assets acquired decades ago have allowed for residential rates of 6 cents per kilowatt hour (kW.h) and 3.2 cents for major industry, the new generating stations and transmission facilities will demand much higher rates simply to break even, let alone produce the net income required to allow MH to move forward supported by a reasonable capital structure.

> As a comparison to electricity rates … Combining actual and projected natural gas bill increases for 2008, it would not be surprising if natural gas customers end up paying 30% more for their natural gas this winter as opposed to the last. With respect to fuel oil, propane, gasoline and diesel, increases experienced are even more severe.
>
> In 1999, when MH purchased Centra Gas, space heating by natural gas … could be expected to come at half or less than half the cost of an electrically-heated home; this is no longer the case. (Now) … space heating by electricity (is) cheaper than by natural gas for all residences other than those that heat by way of a high-efficiency gas furnace. If the trend continues more and more new and existing residences may select or convert to electric heating, driving up domestic electricity load and limiting export sales and profits."

The Board noted that Order 90/08 would be followed by a more detailed Order that would provide further direction, necessary background information and detailed rationale for the rate changes of Order 90/08. The Board also noted that the subsequent Order, which is this Order:

> "… will also summarize and encapsulate the positions of Interveners and MH, the comments of presenters, and the evidence of witnesses all appearing before the Board at the public hearing of MH's GRA, a hearing held over 19 days in the Board's offices in the months of March, April and May 2008."

1.3 Previous Board Directives

In addition to MH's specific requests for Board approval in the Utility's GRA, MH reported on the status of various responses to previous Board Directives that were issued in Orders:

117/06 - A review of Manitoba Hydro's Cost of Service Study Methodology and other matters.

Order 117/06 followed a comprehensive public hearing which reviewed in depth MH's Cost of Service Study Methodology, and provided various directives to modify and refine the methodologies to be used in subsequent Cost of Services Studies. In the recent GRA, the Board and Interveners had the opportunity to consider those modifications and refinements in MH's Prospective Cost of Service Study - 08 (PCOSS -08).

173/06 – Application by Manitoba Hydro for the extension of the approval of the Surplus Energy Program (SEP).

By 173/06, the Board approved the extension of SEP to the earlier of October 31, 2007 or a further application by MH, with the expectation that the SEP would be included for review in MH's 2008 GRA.

176/06 - An Interim ex parte Application by Manitoba Hydro for an Order approving new electricity rates in four communities served by diesel generation, to be effective January 1, 2007.

This was the fourth Order, in a series of Orders (17/04; 45/04; 159/04; and 176/06) that adjusted rates, each provided on an interim basis, in the four communities that Manitoba Hydro services by diesel generated electricity. The communities are:

Barrenlands First Nation (also known as Brochet)

Northlands Dene First Nation (also know as Lac Brochet)

Syisi Dene First Nation (also known as Tadoule Lake)

Shamattawa First Nation (also known as Shamattawa)

The interim rates approved in Order 176/06 (as well as the other interim orders) were predicated on MH filing an Application to finalize all outstanding Diesel Zone Interim Orders, as soon as the Settlement Agreement among MH, MKO, and INAC has been fully executed.

20/07 - Manitoba Hydro - Interim Rate Increase effective March 1, 2007.

1.0 Overview

This Order approved, on an interim basis, the 2.25% average rate increase that MH, in the most recent GRA sought to confirm, and which the Board has confirmed by way of Order 90/08.

By this Order, the Board also comments on MH's responses to previous directives and provides additional directives for the attention of the Utility.

1.4 Board Findings

As was the case with Order 90/08, this Order addresses many complex issues and provides detailed analysis, discussion and decisions (in other sections of this Order) in support of not only the directed rate approvals provided by Order 90/08 but also with respect to other matters deferred to this Order.

For all of the reasons set out both above and in the Board's Findings sections included herein, the fiscal health of MH, along with the affordability of energy for low-income households, remain the Board's greatest concerns. While the Board's concern over MH's financial situation lies largely with the $18 billion of capital expenditures likely to lie ahead, and the debt expected to be incurred to fund those expenditures, the Board's concern for low-income households is with their ability to pay seemingly "ever-increasing" energy bills (not just electricity, but also natural gas, gasoline, diesel, fuel oil and propane).

The Board also notes elsewhere in this Order, findings related to MH's OM&A expenses and the Corporation's efforts at expense control, and observes that the unprecedented planned increase in such capital expenditures are beyond the Board's statutory jurisdiction to approve or deny. Nonetheless, the impact on finance and depreciation expense arising from capital expenditures, along with the risks ever-present with a Corporation dependent in large part on weather and other matters not within its control – general inflation, interest rates, currency fluctuations, represent the largest component of the upward pressure on consumer rates.

In considering its directions and comments, the Board is mindful of past directions from the Manitoba Court of Appeal:

1.0 Overview

> "The Board's function is not only to protect consumers from unreasonable charges, but also to ensure the fiscal health of the corporation and fairness between different classes of consumer." [1]

1. Coalition of Manitoba Motorcycle Groups Inc. v. Manitoba (Public Utilities Board) [1995] M.J. No. 301 (C.A.).

Attention to the fiscal health of MH (as one factor in the Board's determination of the public interest), has been supported by the Manitoba Court of Appeal.

The intent of the legislation is for the Board to approve fair rates, taking into account such considerations as cost and policy, or other factors as the Board may deem appropriate. Rate approval involves balancing the interests of multiple consumer groups (residential, commercial, institutional and industrial) with those of the utility. In the end, the long-term interests of consumers and the utility should coincide.

The Board's decision in Order 90/08 to build retained earnings more rapidly than MH proposed, in order to better protect the utility and consumers from the potentially devastating financial impact of future drought and other identified risks, clearly meets the intent of the legislation and is within the jurisdiction afforded to the Board in s. 26 of *The Crown Corporations Public Review and Accountability Act*.

It should be clear for the reasons cited herein that the Board understood its role in this regard.

> "The (Board) has two primary concerns when dealing with a rate application; the interests of the utility's ratepayers and the financial health of the utility. Together, and in the broadest interpretation, these interests represent the general public interest." [2]

2 Consumers' Association of Canada (Man.) Inc. et al v. Manitoba Hydro Electric Board, 2005 MBCA 55

In arriving at its decision to grant MH rate increases as of July 1, 2008 and April 1, 2009 (the latter conditional), the Board took into account recent financial results and forecasts which, particularly if the forecasts are met, will contribute in a meaningful way to improving MH's financial strength in the near term.

Financial results for fiscal 2007 were $13 million better than projected and the current projection of $300 million (or more) of net income for fiscal 2007/08 represents a gain of at least $96 million over what had been anticipated given median water flows. The Board also understands that energy in storage (water in the reservoirs) was at record or near record levels going into 2008/09 and that water flow conditions remain favourable, both factors suggesting that the current forecasted net income of $156 million for 2008/09, (which was again based on median water flows), may be exceeded.

If these projections prove out, MH will have enjoyed 14 of the last 18 years of above or near median water flows. While such a result would be very good news indeed, history has a habit of repeating itself, particularly when it comes to weather, and years of water flow better than median may very likely be followed by years of below median water flows.

Then, there are the significant concerns expressed over the forecasted increase in capital spending, concerns expressed not only by the Board, but also MIPUG, the Coalition and MKO. The concern is of particular importance as the capital program increases now forecast are, at least initially, driven by export sales commitments.

Interveners suggest a capital justification hearing or, at least, a public dialogue on the appropriateness of the capital program, which brings risks as well as opportunities. The Board shares this view.

And, MH's intended capital program, unprecedented in the Corporation's history, and supported in large part by the expectation of large export sales, also has risks, the larger the commitments the larger the risks.

1.0 Overview

The Board would be remiss if it did not acknowledge that a primary driver of the Board's decision to increase 2008 rates by 5%, 2.1% more than MH sought, was the Board's perspective that attention should be paid to not only reaching but also maintaining the 75:25 debt to equity financial target.

It is not as if MH is already at its 75:25 debt:equity target, or that MH has projected to the Board that it expects to reach and maintain that target. In fact, due to the planned acceleration in capital spending, driven primarily by export considerations, the Corporation is not expected to meet its 75:25 debt to equity ratio target during the current forecast period, which extends to 2017/18, and those forecasts already assume annual average rate increases of about 3% each year.

In addition, major new contracts are being contemplated for export sales that will require new generation and transmission facilities costing over $6 billion, costs which have not yet been incorporated in the forecasts of the Corporation.

That said, the Board was reluctant to raise MH's rates by more than the Corporation sought. The Board is well aware that Manitoba's consumers are facing extraordinary increases in the cost of living caused largely by increases in petroleum prices. High petroleum costs are also translating into higher costs for staples: food, tires, gasoline and diesel prices, and heating oil, propane and natural gas heating costs.

For the Board, in meeting its mandate to serve the public interest, that interest includes the financial health of the Utility. A major capital program, combined with water, interest rate, accounting and currency risks, warrants larger rate increases than those sought by the Corporation, in order to improve the Utility's financial resilience.

1.0 Overview

The Board is encouraged by improved financial projections for fiscal 2008, noting that MH has indicated its financial results is likely to exceed $300 million, an improvement from the $264 million reflected in its previous forecast. The Board further notes that MH has indicated near record level energy in storage and favourable water flows at the outset of fiscal 2009, which bodes well for MH meeting if not exceeding its fiscal 2009 forecasted net income of $156 million. Such improved financial results would also assist in enhancing the financial strength of MH.

The Board notes that the improvement is very much linked to higher volumes of hydraulic generation and is not reflective of increasing export prices or demonstrated cost reductions from previous forecasts.

While MH's fiscal health has significantly improved from the financial impact of the 2003/04 drought, where the loss incurred was the largest in the Utility's history, a future drought, one that could extend over several years, would result in larger generation reductions than the 2003/04 drought brought about, and would result in greater financial loss.

The Board is of the view that further improving the financial strength of MH, regardless of current improved results, is important to the future of the Utility, and that Manitobans, already enjoying electricity rates well below the average found on the continent, and cognizant of the rapid and hyper-inflationary increases for commodities generally (and energy in particular), will accept that an increase of 5% is now necessary.

MH financial strength has a significant influence on the finances of the Province, and MH's financial strength is a major consideration in the evaluation of the credit rating of the Province. In fact, the interest rates MH now enjoys are far below what would be required if not for the guarantee of the Province. The Board further notes that MH has also indicated that the Corporations' debt to equity ratio would have to be similar to that of privately-owned utilities (i.e. 60:40) in order to borrow at rates comparable to the cost of funds received through the Province, without the Province's guarantee.

Any downward adjustment in the credit rating of the Province would likely result in higher borrowing costs for MH as well as the Province, and serve as a double blow against the interests of consumers and industry.

MH rates should gradually begin to recognize the rates required to support new generation and transmission. Given the economic benefits that flow to the current generation of Manitobans as a result of an extensive capital expenditure program and the maintenance of an efficient and effective electrical grid, it seems reasonable that (to some limited extent) the current generation should shoulder some of the rate burden possibly destined for future generations

Leaving aside the weather, maintenance and economic risks that the Corporation faces, there is also the matter of the adoption of IFRS and the consequences for the Corporation once IFRS becomes GAAP. The Board shares the concern expressed by MH's Vice President of Finance and Chief Financial Officer when he testified that IFRS accounting could reduce the Corporation's annual average forecast of net income through to 2017/18 by as much as $120 million a year.

In fact, the Board needs to have MH's risks fully quantified to provide guidance on future rate requirements. And, while revenue alone will not be sufficient to support projected capital spending, MH needs sustained and repeated annual rate increases to support its financial position. Furthermore, the Board is concerned that the recently-announced new export contracts have not yet been reflected in the Corporation's Capital and Resource Requirements analysis, and the Board needs to see an updated Integrated Financial Forecast (IFF), Capital

Expenditure Forecast (CEF), Load Forecast & Power Resource Plan going out to 2028, this beyond the regular forecast period of 2018 to better gauge fully what lies ahead for ratepayers.

For the reasons cited above, and given the overall situation and prospects for additional rate increases as well as borrowings in the future, the Board confirmed as final, by way of Order 90/08, the interim rate increase of 2.25% granted March 1, 2007 on an interim basis. The Board believes that the initial interim increase, which took effect in fiscal 2007/08, was an integral part of the improved financial results for the year just completed.

In light of all the pressures on MH, it is acutely important that the financial strength of MH be improved. In the past MH has been striving to achieve a debt to equity target of 75:25. Although the target was deferred to 2011/12, it now appears that it will not be achieved and held to until well beyond 2017/18.

MH is evaluated by credit rating agencies that are interested in seeing MH making progress toward its financial targets. It is vital that progress continues to be made to ensure no negative implications for the credit rating of the Province. A strong credit rating results in access to capital at reasonable costs. Any deterioration in the credit rating of the Province attributable to MH would likely lead to higher borrowing costs for both the Province and MH.

All this said, the Board does not believe ratepayers alone should shoulder the obligation to maintain the utility's financial health. The Board expects the Corporation to demonstrate and provide evidence of tangible results in the management of OM&A costs and the Capital program, as well as addressing other issues and meeting directives discussed in detail in other sections of this Order.

1.0 Overview

Approval of the conditional 4% increase now slated for April 1, 2009 is dependent on MH addressing (to the Board's satisfaction) certain directives set out in this Order and filing additional financial information to allow the Board to assess whether the conditional increase is justified. The Board will direct MH to file (before January 15, 2009), supporting information for Board review of the 4% April 1, 2009 conditional increase. In addition to the information to be filed with the Board by that date, MH is to include:

a) first, second and third quarter 2008/09 unaudited financial results and statements; and

b) an updated forecast of net income for 2008/09, reflecting existing water energy in storage conditions.

2.0 Operating Results and Financial Projections

2.1 MH's Forecasting Process

MH utilizes four main forecasting tools:

a) The integrated financial forecast (IFF) projects MH's financial results over an 11 year period and includes an income statement, balance sheet and statement of cash flow.

b) The System Load Forecast projects energy and capacity requirements for electricity in Manitoba over the next 20 years.

c) The Power Resource Plan forecasts MH's supply capabilities under dependable flow conditions.

c) The Capital Expenditure Forecast (CEF) includes the planned capital expenditures for a 10 year period including safety requirements, supply side enhancements major generation and transmission projects and investments in administrative assets.

2.2 Comparison of Actual Operating Results with Prior Forecast

The IFF reviewed at the last GRA was IFF03-1, presented at the Board's 2004 hearing of MH's GRA. At that time, MH had just endured a severe drought and was forecasting a loss of $355 million for fiscal 2004. At the 2004 hearing MH provided an update to the Board indicating that the forecasted drought loss would be greater than that reflected in IFF03-1, projecting a loss falling between $400 million and $430 million, which ultimately settled at $428 million.

As directed in Order 101/04, MH filed IFF MH04-1 to justify implementation of the first 2.25% conditional increase, which was granted by the Board effective April 1, 2005.

As a result of the increases granted by the Board, more favourable water levels in fiscal 2005, and higher export sales in fiscal 2006, MH's financial position improved in the order of $130 million over the forecasts of IFF03-1 and IFF04-1.

The favourable water conditions of 2005 and 2006 reversed in fiscal 2007. In January 2007, MH sought from the Board a 2.25% rate increase. In support of its application, MH filed IFF MH06-2, which forecast a $108 million net income for fiscal 2006/07. The Board granted that increase on an interim basis by Order 21/07, and it took effect March 1, 2007.

2.3 Integrated Financial Forecast (MH07-1)

At the most recent GRA, MH filed its most current IFF (IFF MH 07-1) for its electricity operations, as well as its most current capital expenditure forecast (CEF 07-1), both for the eleven-year period 2008 to 2018. The IFF provides an indication of MH's view of its long-term financial direction in both absolute terms and as to achieving its financial targets, and is for use in future planning. MH's operating results since its 2004 GRA are compared to actual and prior forecasts as follows:

2.0 Operating Results and Financial Projections

Statement of Operations & Retained Earnings ($ Millions)	**Actual**				**IFF07-1**	
Fiscal Year	**2004**	**2005**	**2006**	**2007**	**2008**	**2009**
Revenue

Requested Rate Increase	-	-	-	-	-	31
Export	351	554	827	592	582	468
Total Revenue	1,287	1,508	1,828	1,632	1,661	1,607
Expenses						
Finance	455	473	473	472	404	426
Depreciation	276	291	303	314	332	347
Operations & administrative	293	308	322	332	351	360
Water Rentals	71	111	131	112	121	112
Tax expense	51	52	54	55	57	64
Fuel & power purchases	569	135	125	226	132	143
Total Expenses	1,715	1,370	1,408	1,511	1,397	1,452
Net income [IFF 07 - 1]	(428)	138	420	121	264	155
Compared to Prior Forecasts						
Net income (loss) [IFF03-1]	(355)					
[IFF04-1]	-	147	208			
[IFF06-2]	-	-	-	108	174	127
Net income difference	(73)	(9)	212	13	90	28
Retained earnings Actual/IFF 07-1	707	845	1,265	1,386	1,650	1,805
Retained earnings from above IFF	759	854	1,061	1,398	1,572	1,699
Cumulative difference	(52)	(9)	204 -	12	78	106

Domestic electricity revenues are forecast to increase with load growth (usage) and approved rate increases. Export revenue forecasts are based on volumes and market prices, the former limited by water conditions and transmission capacity, the latter on demand and supply conditions in the MISO market (the marginal cost of the next unit of production).

MH's projected net income for the three-year period 2006/07 to 2008/09 is projected to be $131 million higher in IFF 07-1 than the aggregate result for that period forecast in the earlier IFF 06-2 forecast. Incorporating the changes from prior IFF's, as discussed above, MH's net income for the five year period 2003/04 to 2008/09 is now forecast to be over $261 million higher than was the case with the previous forecast.

IFF MH07-1 reflects both the interim increase of 2.25% granted March 1, 2007, finalized by Order 90/08, and MH's requested 2.9% increase as of April 1, 2008, varied to 5% from July 1, 2008 by Order 90/08. The forecast also assumes annual increases of 2.9% for the years 2009/10 through 2017/18. While the Board has already indicated consideration of a 4% increase for 2009/10, later rate forecasts will be the subject of future applications and processes.

MH's decision to file the most current GRA was based on IFF MH06-4, a forecast which projected net income for fiscal 2007/08 to be $249 million, with a further $163 million for fiscal 2008/09. During the GRA, MH provided an oral update to IFF07-1, suggesting that net income for fiscal 2007/08 will be higher by at least a further $36 million. Relative to IFF MH06-4, net income for 2007/08 was then expected to be at least $51 million higher than that forecast. The most recent anticipated improved operating results for fiscal 2007/08 are not reflected in IFF MH07-1, and despite the oral update, MH did not revise its request for a 2.9% increase as of April 1, 2008.

MH advised that its actual financial results for fiscal 2007/08 would not be made available to the Board until mid-June 2008, and, then, only in confidence pursuant to normal legislative reporting requirements.

MH's operating results and forecasts compared to the forecast of the 2004 GRA were as follows:

2.0 Operating Results and Financial Projections

Statement of Operations & Retained Earnings ($ Millions)	Actual				IFF07-1		
Fiscal Year	**2004**	**2005**	**2006**	**2007**	**2008**	**2009**	**Total 2004-2009**

Estimated PUB Approved Increases	-	21	72	75	94	94	356
Export	351	554	827	592	582	468	
Total Revenue	1,287	1,508	1,828	1,632	1,661	1,576	
Expenses	1,715	1,370	1,408	1,511	1,397	1,452	
Net income (loss) [IFF 07 - 1]	(428)	138	420	121	264	124	
Compared to 2004 GRA Forecast							
Net income (loss) [IFF03-1]	(355)	40	31	30	17	29	
Net income difference	(73)	98	389	91	247	95	847
Retained earnings Actual/IFF 07-1	707	845	1,265	1,386	1,650	1,774	
Retained earnings IFF03-1	759	799	830	860	877	906	
Cumulative Retained Earnings difference 2004 GRA vs. 2008 GRA	(52)	46	435	526	773	868	

Overall, since the 2004 GRA, MH's net income has been $847 million higher than that forecast at that time. The increase in net income is due in part to improved water conditions, conditions better than the median results expected, which led to higher than forecast exports. As well, rate increases approved by the Board since the 2004 GRA have contributed approximately $350 million in additional revenue for the fiscal years 2004/05 through 2008/09.

2.4 Board Findings

There has been an improvement in MH's financial results from that forecast in IFF03-1 at the 2004 GRA, notwithstanding the severe drought experienced in 2003/04. The Board further notes that, aided by much better water conditions than expected, record export sales (provided not only by the water conditions but also by the prices obtained following hurricanes Katrina and Rita in the summer of 2005), along with rate increases, brought in approximately $350 million in revenue, and further contributed to the improved results.

The Board would have expected such additional revenue to have significantly improved the financial strength of the utility, as displayed in its meeting its financial targets, compared with the original forecast. Yet it didn't, and the Board is concerned that MH is still not forecasting to achieve its debt:equity target within its forecast period, not by 2011/12 or throughout the entire 11 year forecast ending in 2017/18.

While the forecasts through to 2018 assume annual rate increases of 2.9%, and annual profits that appear to be very large, particularly to a province accustomed to narrow government budget surpluses and relatively modest returns from government enterprises, the Board not only notes the magnitude of the growing asset base on which these earnings are forecast to occur (restrained as it is by asset costs incurred decades ago at very much lower prices than replacement costs), the Board continues to question the "solidity" of the results and forecasts.

While MH advised that its fiscal 2008 net income would exceed $300 million, due to higher than initially forecast water flows, risks abound with respect to MH's longer–term forecasts, particularly:

a) A decline in export contract sales, trending down to 145 GW.h by 2017/18 in the absence of new contracts [the recently announced sales to Minnesota and Wisconsin, if consummated, will reduce this risk];

b) The limitations of the Corporation's ability to export until Conawapa, Keeyask and other Generating resources, including wind, come on line, in conjunction with the expected restrictions on the Brandon thermal plant commencing in 2009;

c) MH's future domestic load growth forecast may prove low, with the risk of consumers switching to electricity from space heating by natural gas, which is now more expensive than electricity except in the case of high efficiency furnaces;

d) MH's Canadian dollar exchange rate forecast assumptions;

e) MH's future export price forecasts are predicated on imposition of a carbon tax, yet there is no current certainty of such a tax being implemented and having a materially beneficial effect within the immediate horizon of IFF07-1;

f) Escalation in construction cost inflation over the past five years. Increases in commodity costs (iron, steel, concrete, copper and nickel for example) have been sharp and sustained;

i) Based on recent experience, current capital expenditure forecasts related to future construction may prove to be low, and actual costs may exceed the forecasts;

j) Recent or good water flow levels suggest an increased risk of a severe drought during a time when MH's capital expansion plans are significant; and

k) The required adoption of IFRS as of MH's 2012 fiscal year (with MH's 2011 fiscal year financial statements required to be IFRS based for comparison purposes).

A further discussion of each of these risk factors is provided later in this Order.

3.0 Forecast Revenues

3.1 Domestic Revenues

In IFF 07-1, MH forecast that at pre-Order 90/08 rates domestic revenues would increase from $1.057 billion (for fiscal 2008) to $1.258 billion by fiscal 2018, a projected increase of $201 million. Additional revenue forecast to arise from assumed 2.9% annual rate increases for each year from fiscal 2008/09 on to 2017/18 was projected to contribute a further $395 million to MH's forecast revenue growth, with total revenue forecast for fiscal 2017/18 to be $1.653 billion.

The forecast of $200 million in additional domestic revenue at pre-Order 90/08 rates reflects projected net load growth of about 3,500 GW.h over the ten-year period. Of this, 2,200 GW.h, almost entirely expected to occur in the first three years of the forecast, relates to projected new industrial load. To the Board, it appears that MH has assumed that a new Energy Intensive Industry Rate, as initially proposed by MH to take effect in 2008/09, will be applied to almost all of the industrial load growth forecast in IFF 07-1.

3.2 Extra-Provincial Revenues

3.2.1 Energy Available for Export

MH's hydraulic generating resources, supplemented by thermal and wind generation as well as imports (the latter source when required) allow for projected annual exports of energy ranging from about 4,000 GW.h to 15,000 GW.h per year, actual volumes to be affected by water flows and domestic load.

Typically, MH has forecast exports (total supply minus domestic load) in each current year on the basis of known water supply conditions. For the second year of a multi-year forecast, MH utilizes known end of Year 1 conditions plus an assumption of median water flow for the second year. The third year forecast, and each year thereafter, uses the long-term mean flow conditions (basically the average experience of the past).

In IFF 07-1 export sales are forecast at:

MH Forecasted Export Sales

Fiscal Year	GW.h	$ million
2008	11,152*	$582 *
2009	7,549	$468
2010	6,608	$416

*Note**

MH has indicated that exports for fiscal 2007/08 will be significantly higher than its forecast due to higher than forecast water flow.

Also, exports assume that in addition to hydraulic generation, MH will have other resources, as follows:

MH Forecasted Power Resources (GW.h)

Fiscal Year	Thermal Generation GW.h	Imports GW.h	Wind Purchase GW.h	Total GW.h
2008	351	880	320	1,551
2009	203	1,194	320	1,717
2010	928	1,948	320	3,194

The export forecast for fiscal 2008/09 of 7,549 GW.h compares to total exports and average export prices in 2005, 2006, and 2007, as shown below:

MH Average Export Prices (2005 to 2007)

Year	2005	2006	2007
Export Revenue ($ millions)	$554	$827	$592
Export Power (GW.h)	10,780	16,034	11,717
Average Price (¢ per kW.h)	5.13 ¢	5.16 ¢	5.05 ¢

When river flows are above average, MH's hydraulic generation resources supply the export of energy surplus to domestic needs. MH provides "clean" energy at competitive prices into American, Ontario and Saskatchewan energy markets.

The following table illustrates the historical average annual export prices achieved by MH, in comparison to natural gas supply prices:

Average Annual Export Prices/Natural Gas Supply Prices

Fiscal Year	U.S. and Canadian Exports (Canadian ¢/kW.h)	Natural Gas Supply (USD/MMBtu)
1993	1.58	1.91
1994	2.54	2.25
1995	2.69	1.75
1996	2.54	1.95
1997	2.33	2.61
1998	2.16	2.41
1999	2.82	2.00
2000	3.43	2.46
2001	3.91	5.03
2002	4.90	3.08
2003	4.89	4.29
2004	4.99	5.16
2005	5.53	6.28
2006	5.19	9.29
2007	5.08	6.67
2008	5.00 (est.)	8.00 (est.)

Until 2004/05, the Corporation's average electricity export prices tended to track and move in tandem with changes in natural gas prices. However, from 2006 average export prices appear to have plateaued at just above 5.0¢/kW.h. This has occurred despite currently-high natural gas prices.

In 2007/08, a dramatic shift in the Canadian/U.S. exchange rate contributed to average export prices moving below 4¢/kW.h for opportunity energy sales, and below 5.5¢/kW.h for firm (dependable) energy contract sales. As illustrated in the following table, the recent price drop appears to be largely related to changes in the exchange rate. However, and as well, the Board notes no indication that prices for dependable energy in USD terms have escalated with inflation.

NEB Average Export Price Data* (converted to U.S. ¢/kW.h)

Date	Exchange Rate (CDN $)	Opportunity Export		Dependable Export		Imports	
		¢/kW.h (CDN)	¢/kW.h (US)	¢/kW.h (CDN)	¢/kW.h (US)	¢/kW.h (CDN)	¢/kW.h (US)
2006							
November	1.14	6.3	5.55	6.1	5.35	5.6	4.95
December	1.16	6.5	5.6	6.4	5.5	5.9	5.1
2007							
January	1.18	6.0	5.1	6.0	5.1	5.6	4.8
February	1.18	8.7	7.4	6.2	5.3	6.0	5.1
March	1.18	6.6	5.6	6.1	5.2	4.0	3.4
April	1.14	6.8	6.0	6.0	5.3	4.0	3.5
May	1.10	5.0	4.55	6.0	5.45	2.0	1.8
June	1.06	4.5	4.25	5.5	5.2	6.0	5.65
July	1.05	4.0	3.8	5.2	4.95	9.5	9.0
August	1.05	4.0	3.8	4.8	4.55	7.8	7.4
September	1.05	3.8	3.7	5.0	4.9	8.2	7.8
October	0.98	3.6	3.7	4.8	4.9	9.8	9.6
November	0.97	4.0	3.9	5.8	6.0	10.0	9.7
December	1.00	6.2	6.2	5.4	5.4	2.5	2.5
2008							
January	1.05	5.2	5.2	5.3	5.3	6.1	6.1
February	1.00						
March	0.98						

Firm dependable export contracts reflect the ’5 x 16 peak period’ (five days/week and 16 hours/day), with most of MH’s exported energy being sold being on-peak and displacing natural gas electricity generation. As previously indicated, export prices in USD terms have, at least until recently, tended to reflect natural gas supply costs.

Current long term export contracts assure MH of export sales of about 2,500 GW.h/year at prices above 5¢/kW.h (5.5¢/kW.h on average for fiscal 2007/08). Other active contracts are shorter-term market based arrangements, and, for them, prices are now running below 4¢/kW.h for sales volumes of 1,500 GW.h/year.

Overall, the above contracts engaged about 50% of tie-line capacity during the ‘5 x 16 peak period’ in 2007/08.

Interruptible opportunity export sales are broad-time spectrum sales that attempt to capture the remainder of on-peak tie-line availability, and relying on shoulder and off-peak periods to maximize total electrical energy sales. These off-peak sales in fiscal 2007/08 accounted for an additional 8,000 GW.h in 2007/08, and brought an average price somewhat below 5.0¢/kW.h.

Contract and other energy sales are as follows:

Export Revenue in CDN ($000)

July/07	36.30	36.30	54.38	79.84	53.78		54.65		39.45
August/07	35.98	35.98	50.08	78.81	52.74		53.41		38.31
September/07	33.93	33.93	37.44	75.39	51.80		52.87		32.94

The above table illustrates MH’s current firm export sales contracts (the first eight columns) and MH’s current opportunity sales (EPE-269). As the Canadian dollar strengthened, export prices in Canadian currency declined: 35% of the export prices realized by MH were in the 3.5 to 5.0¢/kW.h range; 60% of export sales were at prices between 5.0 and 5.5¢/kW.h; and export prices above 7.0¢/kW.h were realized in only approximately 5% of the sales.

The above low pricing situation may not prevail as new export agreements come into play, with potentially-higher environmental premiums. Opportunity sales outside the agreements currently being negotiated are averaging about 5¢/kW.h, as opposed to the 6-7¢/kW.h that MH had previously anticipated.

MH's forecasts of average export prices employed for the second year of each IFF compare favourably with actual prices in fiscal 2004 and fiscal 2005, though at that time, natural gas prices had soared following hurricanes Katrina and Rita and the connection between natural gas prices and MH's export sales were stronger. However, in the last three years MH has over estimated the average CDN $ export price.

Fiscal Year	IFF-2nd Year Price Forecast	Actual Results
2006	6.2¢/kW.h	5.2¢/kW.h
2007	7.5¢/kW.h	5.1¢/kW.h
2008	7.1¢/kW.h[1]	5.0¢/kW.h (est.)

[1] From PCOSS 07/08

MH contends that the current situation of a high Canadian dollar and flatter U.S. electricity prices is temporary. Accordingly, the Corporation's forecasts of future energy prices reflect the assumption of higher prices aided by a substantial environmental premium.

MH's IFF 07-1 appears to reflect export market conditions as experienced in fiscal 2007/08 to the end of September 2007, but also assumes that the

Canadian dollar will return to $1.16 USD/CDN exchange rate by the end of the forecast period (fiscal 2017/18).

The following table illustrates export values employed in IFF 07-1, and shows the difference in export market prices that could be expected should the Canadian dollar remain at or close to unity:

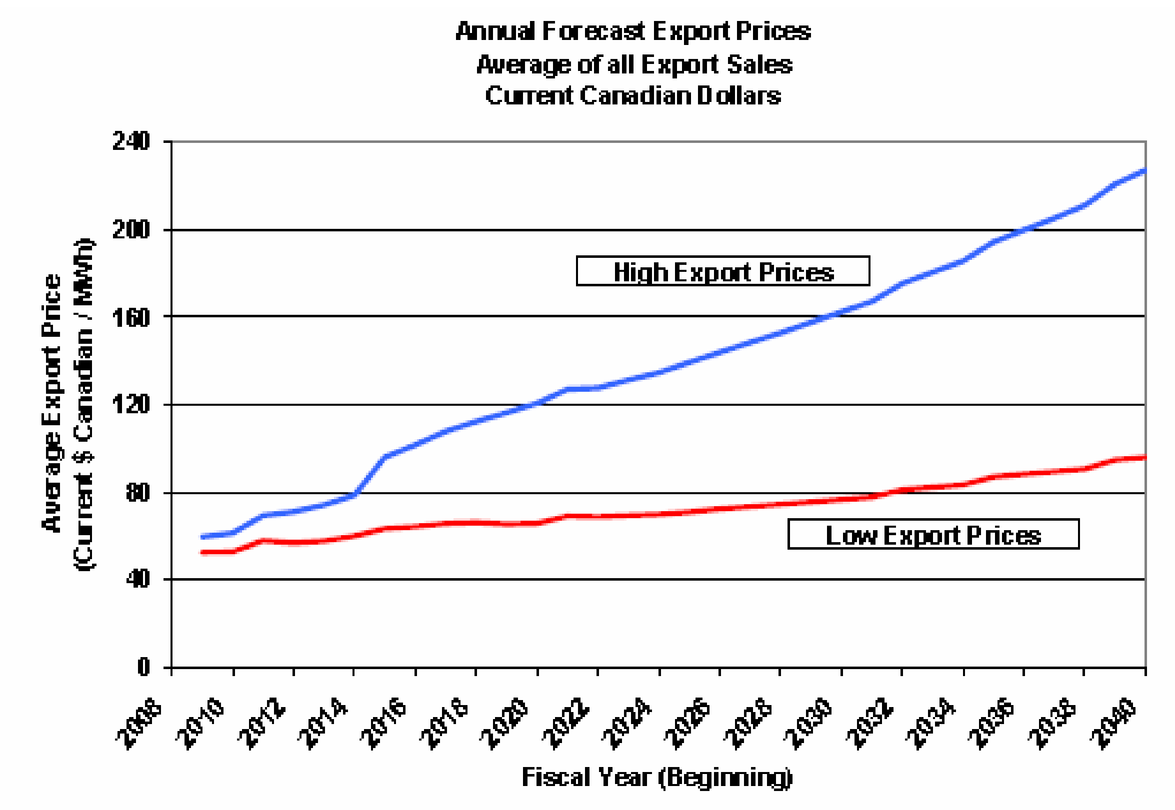
Year	IFF 07-1 (CDN $) ¢ Per kW.h	[1] USD/CDN$ EXCHANGE RATE	[2] IFF 07-1 (Unity) ¢ Per kW.h	[3] Forecast Range PUB/MH II-38 ¢ Per kW.h
2007/08	5.2¢	1.07	4.9¢	5.3-6.2¢
2008/09	6.2¢	1.08	5.7¢	5.3-6.3¢
2009/10	6.3¢	1.11	5.7¢	5.3-6.4¢
2010/11	6.4¢	1.11	5.8¢	5.5-6.4¢
2011/12	6.7¢	1.11	6.0¢	5.9-7.0¢
2012/13	7.1¢	1.13	6.3¢	5.9-7.2¢
2013/14	7.4¢	1.14	6.5¢	6.0-7.5¢
2014/15	7.8¢	1.16	6.7¢	6.3-8.5¢
2015/16	8.9¢	1.16	7.7¢	6.5-10.0¢
2016/17	9.3¢	1.16	8.0¢	6.6-10.5¢
2017/18	10.0±¢	1.16	8.6¢	6.7-11.0¢

Notes:

1 MH's forecast of CDN $ values reflect the average forecast of four independent consultants (all employing a starting exchange rate upward of 1.05).

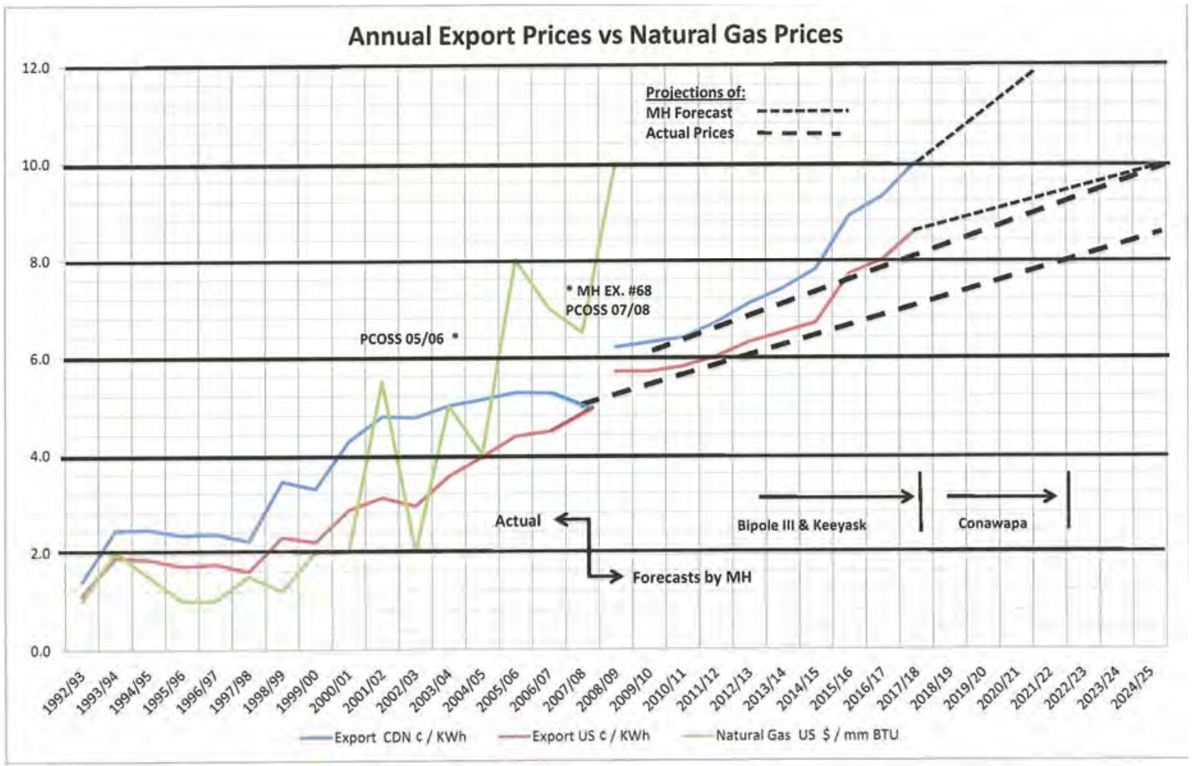
2 IFF-01 export prices recalculated on a unity exchange rate basis for the entire forecast period.

3 In an exhibit provided at the hearing (PUB/MH II-38, below), MH's export energy price market forecast was updated from that of the 2003 Clean Environment Commission application, and suggests a significant upward movement in Midwest Independent System Operator (MISO) region prices will occur in about seven years, assuming past historical exchange rates return.



Comparing IFF 07-1 to the forecast range depicted in PUB/MH II-38 shows that MH anticipates prices in the medium to high range. This would require the exchange rate to return to 1.16 USD/CDN and significant progress on the CO_2 emissions front (recognition of environmental costs reflected in pricing). The 1.5 to 2.0¢/kW.h increase in the high export price curve forecast circa 2015 appears to coincide with MH's anticipation of legislated action on the CO_2 front.

The following chart illustrates that from the early 1990s to about 2004/05, U.S. Export electricity prices achieved by MH (USD) moved in tandem with annual average natural Gas Supply prices. Subsequently, natural gas prices have risen dramatically while electricity export prices (USD) have grown only modestly. In terms of Canadian dollars, the prices have in fact plateaued at about 5¢ per kW.h.



The export energy prices employed by MH in PCOSS–06 and PCOSS-08 were 6.2¢ and 7.2¢ CDN/ per kW.h respectively. In IFF07-1, MH has forecast export prices (USD) to continue a gradual upward movement until 2014/15 when they are expected to step upward in response to carbon tax legislation and continue to rise more steeply to about 8.5¢ per kW.h in 2018. If a steep rise continued to 2022, export prices would be about 10¢ per kW.h.

MH has suggested that USD/CDN exchange rates will return to about 1.16 by 2015; this would yield forecast average export prices of 10¢ per CDN per kW.h in 2018, and 12¢ CDN per kW.h in 2022, and might be sufficient to support new generation and transmission development [Bipole III, Keeyask and Conawapa] if interest rates do not increase. However, if the movement to carbon taxation does not happen, lower prices may well prevail. It can be speculated the prices of 7¢ U.S. per kW.h in 2018 and 8¢ U.S. per kW.h in 2022 would result from projections of recent [2005 to 2008] actual average export prices. If the exchange rate moves to 1.16 USD/CDN as anticipated by MH, the export price forecast would be 8¢ CDN per kW.h in 2018 and about 9.5¢ CDN per kW.h in 2022.

It can be realistically speculated if the costs of Bipole III, Keeyask G.S., and Conawapa G.S. were fully allocated against export revenues, average export sales prices would have to be 11¢ CDN per kW.h to break even.

In the 1990s, natural gas prices were relatively constant $1.50 to $2.00 (USD) per BTU. Natural gas-fired electricity generation (with its low Capital Investment requirements) became very attractive as an alternative to building new coal plants. There were predictions as recently as 2001 that all new generation would be natural gas–fired, and numerous new natural gas generation plants did come into service in Western Canada and the U.S. Midwest.

In 2001/02 natural gas prices almost tripled but fell back the following year, only to renew the upward climb in 2003/04. This led to reduced natural gas generation, and consequently greater exports by MH at then favourable average prices of 3¢ to 5¢ U.S. per kW.h

The advent of Hurricane Katrina in 2005/06 led to a further doubling of natural gas prices. However, MISO average market prices for electricity only increased by about 25% and now appear to be almost static at about 5¢ U.S. per kW.h, even though natural gas prices have been above $11.00 U.S. per MBTU in June 2008 (falling back since). It appears obvious that current MISO market prices for electricity are not being driven by natural gas prices.

The Mid-Continent Area Power Pool (MAPP) merger into MISO after 2000 reduced the relative significance of natural gas generation in determining MH's export pricing. Access to more coal generation could be responsible for the low off-peak prices. Other possible explanations for this disconnect between market electricity pricing and natural gas prices are that:

- Mandated wind generation, when available, could also be used in conjunction with MH's exports during the off-peak period and create base load energy at prices only marginally above coal generated energy.
- Natural gas generated electricity provides a very limited fraction of the total energy consumed within the MISO region; in the 2005 summer, natural gas generation might have been in play about 25% of the time but only supplied about 5% of the total market energy.

Coal-fired Electricity Generation greatly influences MH export markets in the MISO region and, to a somewhat lesser extent, in Ontario and Saskatchewan. Coal based generation is inherently base load in nature (MISO utilities rely on coal and natural gas, hydro is a minor source) and the replacement of coal-fired generation by MH's hydroelectric power currently brings an average market export price significantly below 5¢/kW.h.

Consequently, at the prices MH seeks for its power (prices well above 5 cents), the Utility is not competitive for base load and can achieve export market access at better prices primarily at the time of MISO system peak loads. For MH to compete for base load, a substantial environmental premium would have to exist for clean energy; that is coal generation would have to be "penalized".

In MH's 2003 Clean Environment Commission (CEC) Application to construct the Wuskwatim G.S., the Corporation's energy price forecasts reflected environmental price premiums for its export sales. At the recent GRA, MH suggested that these scenarios are still valid and will come into play within the forecast period. Within its 2003 CEC submission, MH categorized three levels of environmental premiums in 2000 U.S. dollar terms:

- Low (long-term CO_2 valued at $10 U.S./ton)
- Medium (long-term CO_2 valued at $20 U.S./ton)
- High (long-term CO_2 valued at $25 U.S./ton).

For MH's future exports of hydraulic generation to realize prices of 7 cents or more per kW.h, it appears that coal generation by MISO market utilities would have to be assessed substantial CO_2 emission premiums.

Natural Gas Electricity Generation at current natural gas prices can readily be displaced economically by MH exports in the MISO region, even during peak load periods. During off-peak hours, there is little (if any) natural gas generation to displace, resulting in low export prices for the Corporation.

MH's own natural gas generation of electricity is not economical at today's natural gas supply prices. Incrementally, these generation costs range from 5¢/kW.h with natural gas at $3.00 CDN/GJ, to 15¢/kW.h with natural gas at $9.00 CDN/GJ.

MH has suggested that pending U.S. legislation on Green House Gas emissions will make new natural gas generation plants more economically attractive to U.S. utilities, as coal should bring much higher environmental cost premiums than natural gas. Such a development would favour MH and its price forecasts over the longer term.

Wind Generation has essentially been mandated in some U.S. states which now specify minimum levels of required renewable energy (not including large hydro) that must be incorporated within the supply system. As MISO market wind may be displacing MH exports (on an energy supply basis), about one third of the time, MH exports may also be called upon to serve to back up this generating source for the Americans.

3.2.2 Foreign Exchange

As suggested above, MH's export revenue is significantly influenced by the foreign exchange rate.

MH's present forecast of the exchange rate was updated in July 2007, and the exchange rate utilized in IFF MH-07-1 ranges from 1.07 USD/CDN to 1.16 USD/CDN. The exchange rate used for fiscal 2007/08 was 1.07 USD/CDN, and 1.08 USD/CDN was used for fiscal 2008/09, yet the CDN dollar remains close to parity with the U.S. dollar.

MH's exchange rate forecast fails to fully recognize the significant appreciation of the CDN dollar versus the U.S. dollar, and the underlying reasons for the appreciation that suggest the change may persist. This has had the effect of MH overstating both the value of U.S. export sales and finance expense.

MH indicated that if the CDN dollar was to remain at par with the U.S. dollar throughout the IFF forecast period, this would result in a decrease of $170 million in its forecast retained earnings. MH indicated that due to its Exposure Management Program, the exchange impact will be limited to the portion of dollar flows that are not perfectly hedged.

MH remained of the view that over the long term the CDN dollar will weaken against the U.S. dollar, consistent with its long-term 1.16 USD/CDN foreign exchange forecast.

3.2.3 Long-Term Export Contracts

MH has typically entered into long-term export contracts for the sale of dependable energy surplus to forecast domestic customer base loads. By and large, these contracts are for peak (5 x 16) energy sales and reflect a commitment by MH to provide a defined amount of capacity (MW) and energy (GW.h) during the 5 x 16 period throughout a year at an agreed price. MH has also entered into diversity agreements that involve the seasonal exchange of firm energy between the Corporation and a MISO counter-party, at prevailing market rates.

MH currently has executed agreements and/or term sheets for about 3,500 GW.h (900 MW) per year of firm energy for both 2008/09 and 2009/10. These volumes essentially utilize all of MH's dependable energy resources available for export.

The 500 MW commitment to Wisconsin Public Service (WPS), to commence in 2019, will increase MH's firm export requirements to 3,600 GW.h, and this is substantially above forecast dependable energy resources in place at that time. MH will require the Keeyask Generating Station to be in place or, alternatively, will have to employ natural gas turbines to provide the energy. MH will need to proceed with its new generation and transmission plans in a very timely fashion to avoid the high costs that would accompany being obliged to generate power through natural gas, import the power or buy the commitments out.

When the 250 MW contract with Minnesota Power takes effect in 2020, MH will then be committed to supplying 5,000 GW.h of firm energy into the U.S. If Conawapa is not in-service by then, natural gas turbine generation and more wind generation (or imports) will be required to offset a shortfall that could approximate 2,000 GW.h in 2020.

3.2.4 Inter-Tie Limitations

Extra-provincial sales or purchases of electricity are achieved at Manitoba's borders through a number of two-way transmission connections to the U.S., Ontario, and Saskatchewan. Theoretically, MH should be able to export a maximum of about a) 25,500 GW.h/year into the U.S., b) 2,600 GW.h/year to Ontario, and c) 3,900 GW.h/year to Saskatchewan.

To date, MH's maximum annual exports have been 16,000 GW.h, and those primarily went into the U.S. market. This means that about 7,000 GW.h/year can be exported during the 5 x 16 peak period and a further 9,000 GW.h/year during the off-peak periods. Consequently, during median flow years, MH can provide 3,500 GW.h to its existing firm export contracts and another 3,500 GW.h into the U.S. or other markets at peak period pricing. Other available energy can only be exported during off-peak periods, and at significantly lower prices.

During high flow years, MH can be faced with selling about as much as 9,000 GW.h at off-peak prices. This depresses the average export price achieved, but increases overall revenue.

3.2.5 Potential Hydraulic Generation

Reservoirs within the Nelson-Churchill drainage basins allow MH to store water for later generation of electricity. This 'energy-in-storage', held at virtually no economic cost to MH, permits the Corporation to shift energy generation into other seasons of the year to meet variable domestic demand for electricity and to optimize export sales.

At the time of the hearing, MH's energy-in-storage was near the historic high level achieved in 1977 when Lake Winnipeg Regulation and Churchill River Diversion came into service. Lake Winnipeg water levels were at the high end of its operating range; flows on the Winnipeg River and the Churchill River were above normal; Saskatchewan River flows were near normal; and only Red River flows were below normal. This situation augurs well for fiscal 2008/09.

In IFF 07-1, MH predicted hydraulic generation of 31,000 GW.h for 2008/09 (representative of about 1,000 GW.h above the median flow scenario), reflecting the-then (at the time of the forecast being prepared) high level of energy-in-storage and median river flows. Current indications suggest hydraulic generation will remain above median for 2008/09.

3.2.6 Fuel and Purchase Power

In defining "dependable energy" available for export contracts, MH counts on about 4,300 GW.h of thermal energy, available to utilize in a worst-case situation. In reality, MH has typically employed about 800 GW.h of coal-fired thermal generation, but, due to the high cost associated with natural gas, rarely has MH fired up its natural gas-fired thermal generation for delivery of energy to the market.

In IFF 07-1, MH expects to employ thermal generation of 350 GW.h and 200 GW.h respectively in fiscal 2008 and 2009. In subsequent mean (average) flow years, coal generation would be fully utilized to support export sales.

IFF 07-1 anticipated that imports of 1,200 GW.h at a cost of about 5¢/kW.h would be required for purchase in fiscal 2009, with a further 100 MW of wind energy purchases. In mean flow years (that is, average flow conditions), about 2,000

GW.h of imports are expected to be required, in addition to increased wind energy purchases to meet domestic and export commitments.

Power purchase unit costs beyond 2008/09 are forecast to be about 0.5¢/kW.h below average export prices. Presumably, this expectation reflects anticipation of a degree of off-peak purchases for on-peak sales.

MH is also involved in short-term 'energy trading' in the MISO market. MISO transmission rights allow for energy to be purchased from MISO utilities for resale, either to another MISO utility or to Ontario, all within very narrow windows of time. No internal MH generation of energy is employed in short-term energy trading. Usually these trades produce a profit; and both the purchases and sales are recorded in MH's records as revenue and expense.

3.2.7 Costs of Export

As reflected in MIPUG's evidence presented at the hearing, PCOSS-08 results indicate generation and transmission 'bulk power' unit costs for metered energy, as follows:

- Residential 3.72¢/kW.h
- GSS-ND 4.12¢/kW.h
- GSM 3.84¢/kW.h
- GSL>100 3.29¢/kW.h
- Exports 4.83¢/kW.h

These costs neither include existing DSM nor the uniform rate adjustment, nor reflect net export revenue allocations. The class variations in generation and transmission pricing are largely attributable to the impact of distribution system losses and class variable load factors.

If the above values were recalculated at generation, each domestic class would be reported as incurring 3.0 to 3.2¢/kW.h of generation and transmission costs, and exports would be indicated to incur about 4.4¢/kW.h of generation and transmission costs. The latter indicated export cost compares to MH's forecast export price of 7.0¢/kW.h (and the actual export price of 5.0¢/kW.h for 2007/08).

In the absence of exports, MH's total costs would be lower by:

Share of generation and transmission costs	$167 M (including water rentals)
Imports	$134 M
Thermal fuel cost	$ 23 M
MISO, etc./trading distribution costs	$ 20 M
	$344 M

Even without an export operation, MH's costs would still reflect:

Uniform rate adjustment	$ 17 M
DSM	$ 25 M
	$ 42 M

Without an export operation (also without a corresponding import capability), MH's costs would be expected to be higher because of a requirement for the additional usage of natural gas turbine generators, the costs of which are estimated to be between $50 million and $100 million/year.

3.3 Interveners' Position

None of the interveners actively questioned the reasonableness of MH's domestic and export revenue and price forecasts. While RCM/TREE expressed concern about the growth of domestic load and the potential for that to result in reduced exports, the pricing of such exports was not subject to Intervener comment.

3.4 Board Findings

Overall, in the three-year period 2005 to 2008 MH has exceeded forecasted export revenues despite significantly lower than forecast export prices. Substantially above-average water flows and hydraulic generation has allowed for the higher export volumes, which have more than offset the lower prices.

Export prices in the last three years have averaged about 5.0 CDN¢/kW.h for dependable (firm) and interruptible energy sales. These pricing levels, when adjusted for the exchange rate, suggest a 4.6 U.S.¢/kW.h average MISO market rate. This is substantially below MH's IFF projections for the last three years.

MH's dependable sales into the MISO region in 2007/08 earned about 5.3 U.S.¢/kW.h for 5 x 16 energy. This price was similar to that experienced in 2005/06 and 2006/07, for the period of time that followed by a major escalation of natural gas prices after the damages of hurricanes Katrina and Rita were largely repaired and demand fell with weather deviations. It does not appear that export contracts that came into force about 2005 have provided any market price escalation beyond the consumer price inflation.

MH's opportunity sales into the MISO region in 2007/08 earned about 4.6 U.S.¢/kW.h. This price was also very similar to prices in 2005/06 and 2006/07. It also continued to track below the firm energy price - contrary to MH's forecasts of 2005.

MH's export market prospects in Ontario and the MISO region have not improved since the CEC market analysis. Rather, it appears that competition from other energy sources - coal, wind, nuclear and purchased co-generation - are reducing the potential.

Accordingly, MH's projected export prices in IFF 07-1 may be overly optimistic, in that they require additional demand for MH exports and significant environmental premiums in future contracts. American electricity prices are also contingent on achieving decisive U.S. actions with respect to GHG emission controls in the near future.

Overall, there are logical bases for the Board questioning MH's forecast of export pricing in IFF 07-1. Lower export revenues will result if:

- Exchange rates remain closer to unity;
- CO_2 pricing does not progress to a $30 CDN/tonne level in MH's market area within the forecast period;
- New coal generation plant in MISO region does not include substantial CO_2 emission reductions; and/or
- Inter-tie transmission capabilities into MISO are not significantly increased.

Export Sales

For reasons of confidentiality (commercial sensitivity), MH did not provide specific contract energy prices to the Board; the Board was not willing to accept the information in confidence. However, from public information it can be inferred that MH currently has contracts providing 5.5¢/kW.h and may be considering future contract prices that would result in average export revenues of about 7¢/kW.h or less (for firm and opportunity sales) in the absence of legislated carbon pricing in the U.S.

As such, the Board is unable to assert that MH will not be hard pressed to achieve the forecast export energy prices implied in IFF 07-1. Off-peak pricing is usually several cents/kW.h lower than on-peak prices and tends to lower the average export revenue price. It is possible, perhaps probable, that pending contract negotiations will achieve some indexing relative to natural gas prices and inflation. Indexing to coal generation prices (if employed) would rely heavily on possible future carbon pricing, which, as yet, does not have a definitive timeline.

MH export contracts are priced at 5.3¢/kWh, well below forecast average prices of 6-7¢/kWh. Consequently, opportunity sales prices would have to be upwards of 7¢/kWh, levels not evidenced by the information that is available. MH opportunity export sales are expected to return 4.6¢/kW.h in 2007/08 under a high water flow scenario, and these prices did not exceed firm contract prices. In short, MH's export market pricing has not lived up to the potential anticipated in the 2003 CEC market analysis.

MH's IFF 07-1 forecast export prices are based on a low CDN dollar and the presence of environmental premiums (GHG emissions) for both dependable and interruptible export sales. Existing contract and recently-announced term sheet prices do not appear to provide significant market price escalations beyond general consumer price inflation. In fact, MH's IFF 07-1 forecast export prices appear to require substantial carbon emission premiums, likely to be well in excess of recently suggested cap and trade CO_2 prices.

MH's IFF 07-1 forecast prices may only be achieved by a combination of:

- Exchange rate returning to 1.16 USD/CDN;
- New coal plants in MISO being required to show substantial CO_2 reduction; and

- Additional inter-tie transmission capability being added in very near future.

MH's most recent commitment to continue supplying peak energy into the MISO region for the 2010 to 2020 period is expected to backstop substantial new wind energy projects in the region. By taking hydraulic energy from MH when wind is not blowing, the receiving utility will be able to blend the costs and achieve possible GHG savings of wind energy with peak energy contract prices from MH and off–peak energy purchases at typically low spot market prices. The resulting average cost of electricity for the U.S. utility could be below MH's forecast export prices.

This suggests that MH's practice of selling all of its available energy capable of being transmitted during off–peak hours supports MISO's energy blending process. It ensures that, in general, substantial surplus energy is available at low prices during the off–peak.

In the Board's view, it might be in MH's best interest to withhold this energy from the market. At minimum, the Board suggests that MH consider this option and the Board will require that MH file a report on this option, providing the option's pros and cons.

Inter-tie Capabilities

Even in the absence of major new generation, additional inter-tie capability would enhance the value of MH's exports in above median flow years. As yet, MH has not gained formal commitments from cross-border counter-parties to expand inter-tie capacity.

Existing transmission inter-tie capacities are a serious impediment to higher prices; current limits are restricting peak energy sales and resulting in frequent off–peak sales at very low prices.

Recent term sheets signed by MH with Minnesota Power and Wisconsin Public Service offer hope for additional transmission capacity from the Manitoba border into and from the MISO market. This, coupled with new transmission from Riel Station to the U.S. border, could add appreciably to MH's export market potential.

While the concept of an East–West transmission grid has received some political support, there currently seems to be only limited prospects for enhanced export capabilities for MH into Ontario and Saskatchewan. As such, MH does not have an alternative market at the MISO scale.

Hydraulic Generation

MH has enjoyed favourable water supplies in 12 of the last 16 years. On a long-term basis, a reversal of this situation is a virtual certainty. Below median flow years and droughts are in the Corporation's history and can be expected on a regular basis; MH has had a beneficial "run" of better-than-normal water flow conditions now for the better part of two decades, a period of time that has seen MH's highest and lowest net income years (the lowest being the drought year of 2003/04).

Because energy-in-storage normally cannot be substantially carried from year to year, lower hydraulic generation during the forecast period through 2017/18 is an issue of realistic possibility. Export sales are likely to be reduced significantly in below-average flow years, and increased imports at higher cost per unit than the unit value of sales can also be expected in such years.

In the absence of higher export sale prices, MH should expect lower export revenues as hydraulic generation reverts to median, near-normal and below-median levels in the upcoming years. The favourable water supplies experienced in 12 of the last 16 years cannot be expected to continue without interruption.

While MH does not provide specific contract information for reasons of commercial sensitivity, access to this information is essential in order to confirm existing and projected contract prices of between 5.5¢/kW.h and 7.0¢/kW.h, and to ascertain what environmental escalation assumptions are being “banked” on. Given the crucial nature of these contracts and assumptions and potential impact on domestic rates, the prior review of upcoming export contracts by this Board would seem wise and appropriate.

Fuel and Purchased Power

A number of questions require responses in assessing MH’s forecasts, these include:

- Does IFF 07-1 adequately represent MH’s prospects for domestic and export revenues?
- Has MH adequately defined potential energy for export sales, export sale prices, and energy purchase costs (thermal fuel, wind, and imports)?
- MH’s coal generation, on a fully costed basis (approximately 6.5¢/kW.h), probably can compete in the MISO market during the peak load periods as it would displace gas generation. On an incremental fuel and variable Operating and Maintenance cost basis (approximately 3.5¢/kW.h) MH’s coal generation is an attractive export product.
- If the Brandon Coal Plant is either ’moth-balled’ or limited to emergency operations after 2011/12, in accordance with the announced intention of government, MH will have to expect to import, in a median flow year, an additional 800 GW.h at a cost of between $10 - 20 million/year.

- The allocation of MH's system costs in PCOSS-08 suggests that exports incur up to about 5.0¢/kW.h in costs for generation and transmission. Recent average export prices have been only slightly above this cost level.
- With the large investments required to meet domestic load and committed and/or contemplated export levels, there may be a need for export revenue prices even higher than the average 9¢/kW.h projected for 2017/18 under IFF 07-1. An updated IFF that extends out to at least fiscal 2027/28 should be provided to the Board by MH, this to project export revenue requirements and domestic rate levels required to support the current assumptions as to the economics supporting export commitments and capital expenditure plans.

In light of the many complex issues and questions related to MH's export program, the Board will direct MH to file a report by January 15, 2009 addressing the following:

a) An Overview of strategy, options, and historical costs and revenues;

b) Historical prices (monthly for the last five years) for exports including both on peak and off-peak;

c) Existing and pending contract commitments with forecast revenues, both aggregated and also disaggregated (in confidence if necessary);

d) Forecast export revenues – until 2028 identifying opportunity sales distinct from firm contract sales- broken down by on/off-peak;

e) Detailed assumptions used in market price forecasts (filed in confidence if necessary);

f) A testing of MH's assumptions through detailed sensitivity analysis for upper/lower quartile water flows, foreign exchange, domestic load growth and natural gas prices; and

g) Given the crucial nature of these export contracts and assumptions and the potential impact on domestic rates, MH file for Board review all upcoming export contracts.

4.0 Finance Expense

4.1 Changes in Finance Expense

The Corporation's finance expenses were $454 million in 2003/04, then-representing over 26% of total operating expenses. Finance expenses increased to $472 million in fiscal 2006/07, yet for the fiscal years 2003/04 through 2006/07 actual finance expenses were $172 million lower than forecast in IFF 03-1 (2004 GRA), as a result of declining long-term interest rates and the strengthening of the Canadian dollar.

MH forecast finance expenses of $404 million for fiscal 2007/08, and to increase by $22 million to $426 million in fiscal 2008/09 (the latter then to represent 29% of forecast annual operating expenses). The increase is attributable to higher debt levels and to a lesser degree, an increase in the debt guarantee fee paid to the Province, in aggregate offset by foreign exchange gains on the sinking fund related to changes in accounting standards for financial instruments (discussed below).

MH capitalizes interest on all capital projects during the construction phase, and does not amortize these costs and reflect them in rates until the project is in service. MH's finance expense for its electric operation before capitalized interest was forecast at $515 million for fiscal 2008/09 and $426 million on a net basis, after deducting capitalized interest of $89 million.

MH's gross finance expense is forecasted to grow to $906 million by 2017/18, and to $616 million on a net basis (again, after adjusting for capitalized interest of $290 million).

4.0 Finance Expense

Finance expense and capitalized interest for the years 2009 through 2018 are as follows:

Finance Expense ($ millions) For the years ended March 28/29	**IFF MH07-1** 2009	2010	2011	2012	2013	2014	2015	2016	2017	2018
Gross Finance Expense	$ 515	$ 572	$ 609	$ 640	$ 657	$ 695	$ 756	$ 803	$ 864	$ 906
(Less) Capitalized Interest	(89)	(126)	(158)	(141)	(104)	(152)	(209)	(247)	(285)	(290)
Total Finance Expense	$ 426	$ 446	$ 451	$ 499	$ 553	$ 543	$ 547	$ 556	$ 579	$ 616
% Capitalized	17%	22%	26%	22%	16%	22%	28%	31%	33%	32%

MH forecast that its debt would grow from $8.0 billion in 2008/09 to $13.6 billion in 2017/18, a projected increase of $5.6 billion. The major increase in finance expense (before and after the deduction for capitalized interest) relates to the planned new major generation and transmission projects.

Over the planning period to 2017/18, capitalized interest is expected to aggregate to $1.8 billion. And, once the projects are in-service, the interest costs that have been previously capitalized will begin to be amortized/expensed, to be recovered in MH customers' rates.

In addition to the major capital expenditures included in the capital expenditure forecast provided at the hearing, MH also indicated that due to potential new export contracts, it may incur at least $6 billion more in capital costs and debt for additional required major generation and transmission facilities.

If these plans are implemented, MH's long-term debt may approach $20 billion by 2022, a large number, particularly in comparison with current provincial debt of approximately $11 billion.

4.2 Exposure Management Program and Foreign Exchange

MH has an Exposure Management Program (EMP) to manage the Utility's exposure to USD-foreign exchange fluctuations. The EMP operates by establishing a natural hedge between USD cash inflows from export revenues and USD cash outflows (long term debt coupon and principal payments, thermal fuel purchases).

The Overall Exposure Strategy concerns itself with a horizon of up to 30 years, and attempts to limit overall US foreign exchange fluctuations to within a range of + or – 20% of total debt. Only the portion of the USD inflows and outflows that are not matched under MH's EMP may affect annual net income. Fluctuations outside the 20% parameter are valued at the market exchange rate, and affect the annual financial result. The exchange rate at year-end is used for the balance sheet presentation of USD-denominated debt and investment instruments.

Commencing with 2007/08, the new standard of the Canadian Institute of Chartered Accountants (CICA) for the recognition and measurement of financial instruments and for hedges will apply to MH, and the forecast result was included in the IFF MH07-1.

The new standard requires significant changes in MH's accounting for financial instruments and hedging relationships, as well with respect to the recognition and presentation of foreign exchange gains and losses in annual financial statements. The change is expected to result in positive impacts to net income in the first two years of the new standard, benefiting 2007/08 by a forecast $37 million and 2008/09 by $9 million.

As a result of the implementation of the accounting change, the Board notes that MH has forecast amending opening retained earnings for 2007/08 by a one-time increase of $65 million.

4.3 Debt Management

4.3.1 Long Term Debt

MH's debt was $7.3 billion as at March 31, 2007, and forecast to increase to $8 billion by March 31, 2009. MH must rely on debt as its primary source of capital to finance new major generation and transmission projects, as government does not inject capital into the organization but relies on retained earnings from operations to provide capital.

To hold borrowing to a minimum required level, MH funds all routine capital construction from internally generated funds (i.e. from net income). Non-routine and major capital expenditures under way or planned include major new (other than the Pointe du Bois revitalization) generation and transmission projects and the new downtown Head Office building.

MH is in an expansion mode with planned capital spending of $11.3 billion over the eleven year period between fiscal 2007/08 and March 31, 2018. Over that period MH plans on spending $3.8 billion on its regular capital program and $7.5 billion on New Generation and Major Transmission and the Head Office project, as previously reported. As the result of recent export undertakings, yet to be formally confirmed, MH also expects to expend and borrow a further $6 billion by 2022, in addition to the $11.3 billion noted above.

Generally, and on average, debt financing is expected to fund approximately 62% of capital expenditures, with the remaining 38% to come from increased retained earnings, the latter from domestic rates and net export profits – the percentages reported excluding the additional $6 billion of debt related to above.

All in, including the additional $6 billion, MH forecasts an increase in its debt, from 2008's $7.3 billion to almost $20.0 billion by 2022.

4.3.2 Fixed vs. Floating Rate Debt

Pursuant to *The Manitoba Hydro Act*, MH's short-term debt limit has been set at $500 million; MH uses short-term debt to fund seasonal working capital requirements and bridge the timing before new long-term debt issues.

Historically, and in a typically upward sloping yield curve environment, the borrowing costs of fixed rate long-term debt tends to be higher than for short-term debt, though long-term debt fixes the interest rate for the full and longer period of the term, therefore reducing the risk of having to refinance at higher rates. In contrast, the borrowing costs of short-term or floating rate debt tend to be lower on average than for long-term debt, but are fixed for shorter periods, increasing the risk of having to refinance the debt at higher interest rates.

MH's reported policy is to limit the level of its floating rate debt to no more than 30% of total debt outstanding, and to manage the level of floating rate debt within a target range of 15% to 25% of total debt.

MH utilizes these target guidelines in an effort to provide rate payers with the economic benefits associated with the typically lower interest rates of short-term debt while protecting their customers against the risk of higher refinancing charges by reliance on the majority of borrowing being through long-term bonds.

MH's percentage of floating rate debt at each quarter end over the past three fiscal years has been:

Period Ended	Floating Rate Portion
Mar-2004	21.85%
Jun-2004	19.33%
Sep-2004	18.58%
Dec-2004	19.34%
Mar-2005	18.76%
Jun-2005	17.88%
Sep-2005	18.18%
Dec-2005	18.00%
Mar-2006	16.61%
Jun-2006	17.52%
Sep-2006	17.71%
Dec-2006	18.20%
Mar-2007	18.98%

Over the past four years, long-term interest rates have been at recent historic lows, and MH's general preference during this period has been to fix the majority of its new financing at the relatively attractive and low long-term interest rates. The strategy of favouring long-term fixed rate financing during periods when long-term interest rates are low relative to historic norms, and when the premium associated with long-term fixed rate debt is low and the yield curve is relatively flat, may produce costs over the long-term similar to that of a strategy of adding more floating rate debt, but with the added benefit of reducing the volatility of interest expense.

4.3.3 Sinking Fund Management

MH's bonds obligate the Corporation to establish and maintain a sinking fund, that are segregated investments held towards ensuring repayment of the debt. This obligation is currently legislated.

The legislated minimum contribution requirement is 1% of the long-term debt outstanding at the end of the previous year, plus 4% of the balance of the sinking fund at that date. Contributions for fiscal 2007/08 and 2008/09 will be equal to the legislated minimum, and total approximately $100.6 million and $109 million, respectively. MH has $246.5 million of USD denominated debt maturing during fiscal 2008/09, which is forecast to be fully retired through the sale of the related sinking fund investments.

MH reported that changes to CICA accounting standards with respect to Financial Instruments have made sinking funds less valuable, and, as matters were currently understood, the Corporation did not foresee any negative impacts from either borrowing at current interest rate levels, or to access capital from an elimination of the sinking fund requirement from its Act.

MH alluded to a possible transitional phase that could be considered that would, over a few years, substantially reduce or eliminate the Sinking Fund. MH has further suggested that such an elimination might be associated with a forecast cost saving of $93 million over the 11 forecast years of IFF07-1.

4.4 Interveners' Positions

The Coalition

The Coalition observed that MH has kept floating rate debt at about 20% of the Corporation's overall debt portfolio, which now exceeds $7 billion. The Coalition noted that MH's longstanding policy is to have no more than 30% of its debt in the short-term floating category, and that it has held to a target guideline of between 15% and 25% of total debt for the category. The Coalition noted that the policy is over 20 years old and cited studies indicating that employing a higher proportion of short-term floating debt than has been and is the current practice may lower interest costs and reduce finance cost volatility.

The Coalition submitted that while floating debt appears to offer economic benefits, high levels of such debt doesn't necessarily lead to the lowest level of risk. Coalition stated that with MH's overall debt in excess of $7 billion and with the current level of short-term debt in the range of 15 to 25% of that total, there appears to be a potential to move approximately $700 million of currently long-term debt to short-term, and that if by so doing MH was able to reduce its interest cost by a mere five basis points, annual savings of $3.5 million would result.

The Coalition expressed concern that MH has been managing its floating debt policy at the bottom end of the 15 to 25% range, and noted that in the 13 quarters between March 2004 and March 2007, MH's proportion of floating debt was below 20% for 12 of the quarters. While not suggesting mismanagement of the debt portfolio, the Coalition suggested the potential for savings and the level of risk related to decisions to be made warranted a re-examination of the current policy.

The Coalition recommended that the Board request MH to engage an independent review of its floating vs. fixed target range maximum, with consideration of options to be in terms of economic benefit and stability.

MIPUG

MIPUG requested that the Board direct MH to seek relief from the province with respect to all sinking fund requirements as soon as possible, and that the sinking fund requirement for MH's debt should be eliminated. MIPUG noted the projections of savings to come with such elimination, that being $93 million over the IFF07-1 forecast period. MIPUG noted that MH had indicated that the Corporation does not expect that the elimination of the sinking fund requirements would have any adverse affect on its borrowing rates, its ability to access capital markets, its available range of borrowing instruments, or the debt rating for the Province of Manitoba.

MIPUG suggested this was an urgent matter, given the scale of borrowings anticipated over the next 15 years, and in light of the forecasted reduced cost of longer-term borrowing.

4.5 Board Findings

Finance Expense

The Board is concerned that the projected growth of finance expense through to 2017/18 and beyond is being obscured by the increasing amount and percentage of interest being capitalized i.e. $89 million or 17% of gross finance expense in 2008/09, to increase to $290 million or 32% in 2017/18. Given MH's expansion plans are consummated, MH's debt is expected to increase to about $20 billion by 2022, and gross finance expense is expected to almost double from 2008/09 levels to over $900 million in 2017/18, while the annual amount of capitalization of interest is expected to more than triple, masking the cash cost of financing major new generation and transmission projects, costs that will ultimately have to be recovered in rates.

The Board notes that MH's policy and practice of capitalizing interest raises a question of the risk of inter-generational inequity, and requires close examination. That said, the Board realizes that if less capitalization occurred, then more of MH's current years' interest costs would be expensed and reflected in rates. In short, without capitalization, the ratepayers of today through to those of the era when the new generation and transmission assets would be in-service would face increased rates to finance capital projects, projects intended (other than through the economic benefits associated with construction) to benefit future ratepayers.

Thus, the Board accepts there is an argument for MH's current approach. To expense costs in the current period and reflect them in current rates when the costs related to the projects are not expected to provide "rate related" benefits until the future would mean charging the current generation of MH's customers for costs that, arguably, should be met by future generations.

The major question relates to risk and conservatism with respect to financial planning. Probably the best approach is a balanced one, an approach that would have current ratepayers pay for some of the costs of proceeding with new projects – which will generate current economic benefits for the Province – while holding future generations responsible for the majority of these costs, as it is those future generations that are intended to reap "rate-related" benefits from the new construction.

The potential for the approach to change lies in part with the upcoming adoption of IFRS. The new standards may not allow MH to capitalize costs for future amortization to the same degree as is now occurring. And, as indicated above, expensing costs that are now being capitalized in the period incurred will result in future ratepayers' rates being reflective not only of "current" costs, including currently amortized costs, but also cost burdens that would otherwise have been reflected in future rates for future ratepayers.

For the welfare of succeeding generations, this generation will likely have to shoulder more responsibility for the costs and risks being assumed by the capital expenditure plans of MH. This was the experience with the prior development of generating stations in the lower Nelson River – i.e. there is precedent for less capitalization of current debt costs.

Fixed versus Floating Debt

As to what represents the optimal mix of fixed vs. floating debt, the Board agrees that increasing the exposure to short-term floating rates would likely benefit current ratepayers in lower finance costs in the near term, but it might also expose future ratepayers to greater volatility and risk over the long-term (as and if interest rates increase).

Given that the debt, by its very nature, has been incurred to fund capital assets with expected lengthy service lives, MH's approach of funding the majority of its debt requirements with fixed term debt appears reasonable.

However, with the anticipated unprecedented growth in debt levels, the Board sees merit in the concerns raised by the Coalition and agrees that MH's longstanding policy related to floating debt would benefit from an independent review. Such a review may suggest a different mix between fixed and floating debt, which may reduce finance expense.

Because of the potential for MH's overall debt level reaching $20 billion, possibly over twice the debt taken on by the province on its own account (with all debt guaranteed by the province) the Board will direct MH to engage an external assessment of the Corporation's relative weighting of fixed vs. floating debt, and file a report with the Board on or before June 30, 2009.

Sinking Fund

The Board notes that elimination of the sinking fund requirement has been forecast to result in savings of $93 million over an eleven year forecast period. While the potential savings are alluring and demand a consideration of the positions of interveners and the views of the Utility, the Board believes that MH has been served well in the past by the obligation to have sinking funds. Yet, the Board accepts that its future benefit may be diminished due to changes in accounting standards and improvements in the capital markets.

The Board understands MH's perspective that elimination of the sinking fund requirement will have no impact on the credit rating of MH or the Province, nor would it limit MH's access to the capital that it clearly needs to proceed with its expansion plans.

Out of an abundance of caution, and in light of the major capital expansion and related anticipated growth in debt levels now planned, the Board will recommend that MH seek independent advice, as well as advice from government and its credit rating agencies, as to the merits of a possible elimination of the sinking fund requirements.

5.0 Operating, Maintenance, and Administrative Expenses (OM&A)

5.1 General

Over 74% of OM&A costs relate to labour costs, which include employee benefits extending to pension obligations. Actual and forecast OM&A expenses for fiscal years 2004 to 2009 are:

Operating and Administrative Costs ($000's)	Actual				IFF07-1	
Fiscal Year	2004	2005	2006	2007	2008	2009
Labour						
Wages, Salaries & Overtime	343424	354,661	370,289	383,597	411,091	425,514
Employee Benefits	59,154	68,442	70,184	73,636	78,335	79,902
	402,578	423,103	440,473	457,233	489,426	505,416
Other Expenditures

Building & Property Services	21,799	21,031	22,973	24,697	24,522	24,700
Equipment Maintenance	9,571	9,546	10,720	11,606	12,235	12,475
Consumer Services	5,081	4,203	4,301	4,316	4,881	4,980
Computer Services	4,547	3,959	4,293	2,622	1,077	1,102
Collections	5,035	5,161	6,790	7,218	5,359	5,466
Customer & Public Relations	4,956	5,223	5,585	6,493	4,581	4,698
Sponsored Memberships	1,163	1,149	1,012	1,187	1,172	1,197
Office & Administration	14,996	15,448	15,904	14,939	15,532	15,882
Communication Systems	2,027	1,844	1,447	1,866	1,834	1,870
Research & Development Costs	3,742	3,685	3,542	3,251	3,414	3,483
Miscellaneous Expense	1,957	2,461	2,143	2,423	2,757	2,812
Contingency Planning	-	-	-	-	4,941	7,254
Operating Expense Recovery	(17,263)	(18,104)	(19,199)	(20,579)	(19,806)	(20,192)
Total Costs	542,660	569,749	596,231	615,852	657,103	679,000
Less: O&A Charged to Centra	(52,786)	(55,232)	(53,085)	(53,505)	(56,600)	(58,000)
	489,874	514,517	543,146	562,347	600,503	621,000
Capital Order Activities	(147,693)	(157,730)	(170,459)	(176,994)	(196,853)	(207,500)
Capitalized Overhead	(58,824)	(58,174)	(62,028)	(61,887)	(63,450)	(64,500)
O&A Costs Attributable to Electric Operations	283,357	298,613	310,659	323,466	340,200	349,000
Number of Customers	501,650	505,660	509,791	516,861	520,259	524,220
OM&A Cost Per Customer ($)	565	591	609	626	653	665

Total OM&A expenses attributed to electric operations and after allocations to Centra Gas and the deferral and capitalization of such expenses to be amortized in future periods have increased from $283.4 million in 2003/04 to $349 million in 2008/09, a compounded annual growth rate of over 4%.

MH indicated that over the last few years, the Corporation has experienced cost and operating program pressures relating to: increased maintenance requirements (due to aging infrastructure); wage and benefit settlements that exceed inflation; additional overtime and increased staffing levels (to meet extra-provincial requirements); the expansion of programs (to meet higher customer numbers) and needs; and the meeting of environmental and other stakeholder expectations. These pressures were reported to be continuing and being compounded by a looming shortage of skilled labour, manifesting itself in higher training and labour costs.

MH stated that the annual compound growth in labour and benefit cost per Equivalent Full Time (EFT) position has averaged 3.8% over the period 2002 to 2007. The increases are due to a combination of general wage increases, merit and/or pay schedule increments, and other adjustments. MH reported that wage and benefit settlements that have been above the general inflation rate reflect higher compensation requirements for attracting and retaining skilled trades and professional staff and, as well, higher compensation requirements for northern staff.

Unfortunately, MH was unable to provide a segregation of OM&A expense associated with maintaining/sustaining existing assets versus expenses associated with changed processes and plans and actions related to construction of new plant.

5.2 Staffing Levels

MH indicated that between 2005 through 2009, its staffing levels were projected to increase further, by 455 EFT employees (from 5,866 to 6,321), with related labour costs to increase by $102.8 million. These increases were reported to be largely due to increased work requirements, with the largest additions expected for staffing levels in Power Supply (234 EFT) and Transmission & Distribution (142 EFT). MH attributed the growth of 180 EFT's between fiscal 2004/05 and 2008/09 as being related to meeting the Corporation's operating and maintenance needs, particularly given the plans for major expansion.

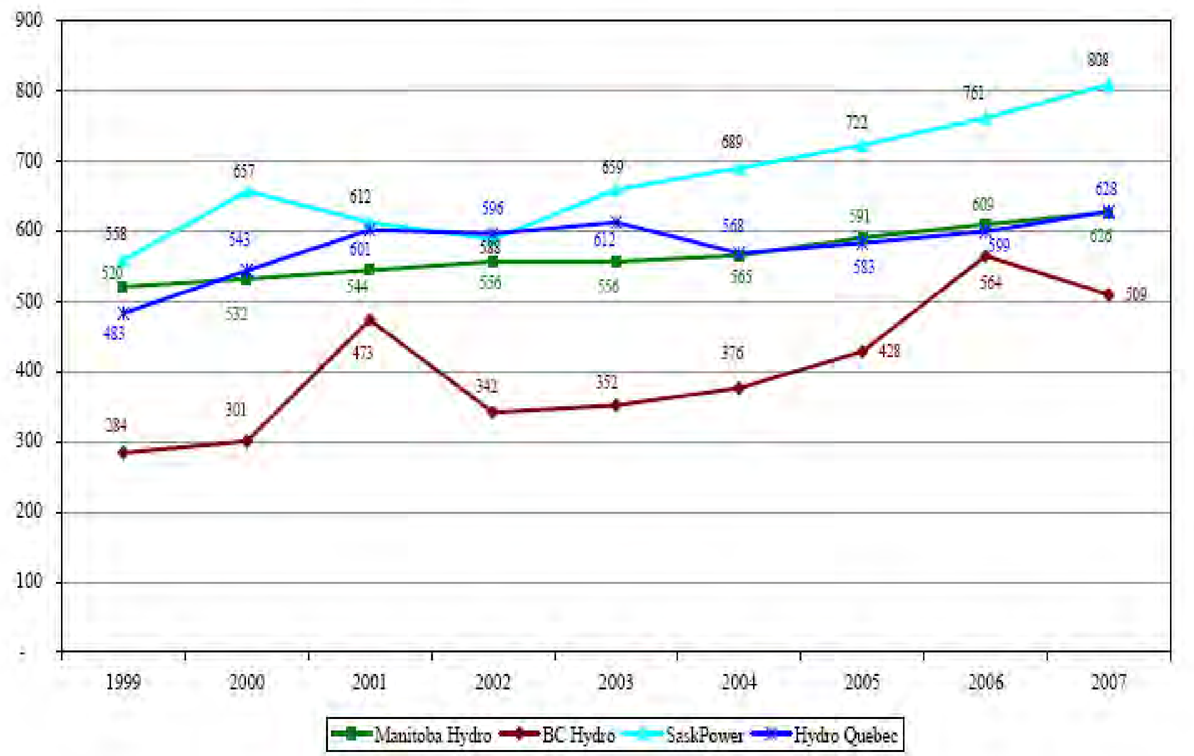
MH indicated that currently there were 200 unfilled EFT positions from the staff level forecast for fiscal 2007/08, and that between 125 and 150 of the EFT vacancies were due to difficulties in recruiting. The remaining unfilled positions were reported to be the result of awaiting the completion of the new head office and expected staff synergies to arise as a result of the consolidation of staff in one location. MH further noted that the hiring difficulty associated with the skill shortage had resulted in forecasted fiscal 2007/08 OM&A costs being $16 million less than forecast for the ten months ended January 31, 2008.

5.3 OM&A Costs per Customer

MH OM&A costs per customer have increased from $565 in 2004 to $626 in 2007. While MH indicated that it was not appropriate to directly compare its OM&A cost per employee to the ratios of other utilities, it noted that based on annual report information, Hydro Quebec's OM&A cost per customer was $628, BC Hydro's cost per customer was $509 and SaskPower's was $808, in 2007, as noted in the following graph.

MH compared its OM&A cost per customer with the other utilities for the years 1999 to 2007:

Manitoba Hydro
Operating & Administrative Expense per Customer
Comparison to BC Hydro, SaskPower and Hydro Quebec



MH reported that its OM&A expense per customer experience, relative to its established targets in the Corporate Strategic Plan, is as follows:

Fiscal year	CSP Target	Actual
2004	$600	$565
2005	$584	$591
2006	$600	$609
2007	$612	$626
2008	$640	$653 (est)
2009	N/A	$665 (est)

The Board notes that MH's OM&A costs and OM&A expense per customer levels were and are materially reduced by the capitalization of significant amounts of OM&A, making the comparisons with the other utilities of questionable value.

5.4 Capitalization of Operating and Administrative Expenditures

5.4.1 Current Capitalization Practices

MH segregates costs between operating activities, which are charged against the operating income for the year, and capital activities, which are charged to future periods and amortized over the future life of the capital project. MH capitalizes certain of its OM&A expenditures.

Many of the expenditures are capitalized as deferred charges, and are amortized over a period of years; others allocated to construction in progress and amortized once the asset is in service over its expected service life.

MH indicated that employee's timecard their activities to specific capital projects. This amount, combined with other related costs, is charged to a capital order. In addition, MH also capitalizes 'overhead' by applying predetermined overhead rates to all capital projects.

OM&A expenses were $615.8 million in 2006/07, that is <u>before</u> capitalized activities and overheads. MH indicated that approximately 29%, or $177 million of the $615.8 million, was charged to capital order activities with an additional 10% ($61.9 million) charged as capitalized overhead. Overall approximately 39% of OM&A was capitalized.

MH forecast OM&A expenses of $679 million for fiscal 2008/09, of which $207.5 million (30%) is to be charged to capital order activities and $64.5 million (9%) as capitalized overhead.

MH capitalizes annually in excess of $60 million of overhead costs to its capital projects, to be amortized when the capital asset goes into service. In addition to the capitalized overhead, MH also includes some overhead costs to determine its activity rates, which are used for allocating direct costs of labour to operations or to capital projects.

MH also capitalizes Demand Side Management (DSM) expenditures arising from its Power Smart program. DSM program costs are deferred and amortized on a straight-line basis over 15 years, regardless of the expected present value of the benefits to be realized.

The carrying value of deferred DSM was $123 million at March 31 2007, and forecast to reach $180.9 million as at March 31, 2009.

Planning Studies involve costs related to uncommitted major generation or transmission facilities. These costs are recorded as deferred charges and are amortized to operations (expensed) on a straight-line basis over 15 years. If there is reasonable assurance that a project will proceed to construction, any unamortized balance related to that project is then transferred from deferred charges to construction in progress. The carrying value of the Unamortized Planning Studies balance was $28 million as at March 31, 2007 and forecast to be $22.5 million as at March 31, 2009.

Construction in Progress consists of contracted services, direct labour, material and expense, a proportionate share of overhead costs and interest applied at the weighted average cost of capital related to projects in development. Once the projects become operational, the costs are recovered in rates through depreciation and finance expense.

Establishment of the Affordable Energy Fund (AEF) by the provincial legislature, was funded by an allocation of electricity export revenues, and is to be used to fund low-income energy efficiency initiatives throughout the Province.

The AEF resulted in the creation of a $35 million deferred charge (asset) and a corresponding $35 million deferred credit (liability) in MH's financial accounts (balance sheet). Annual program expenditures from the fund are to be expensed against income in the year incurred, with the corresponding asset and liability reduced by the equivalent amount.

The balance of the AEF at March 31, 2007 was $34 million, after deductions for low-income related DSM project expenses, including overhead allocations, and the balance of the AEF as of March 31, 2009 was forecast to be $28 million. No interest accrues on the balance.

Goodwill of $62 million related to the 1999 acquisition of Centra Gas Manitoba Inc. and $46 million of additional goodwill associated with the acquisition of Winnipeg Hydro (WH) remains on MH's balance sheet. Goodwill represents the difference between the purchase prices paid for these enterprises and the values assigned to specific assets obtained. Goodwill is not amortized unless judged to be impaired, and impairment tests are performed annually in accordance with GAAP requirements – to-date, these tests have not indicated any impairment of the recorded goodwill.

MH also capitalizes experience gains and losses on its Employee Pension Plan, and amortizes the net result over the expected "life" of the employee group. The unamortized balance was reported to currently be in the $30 million range.

As of March 31, 2007, MH had $457 million of deferred charges recorded as an asset, including rate-regulated assets which, if MH were not subject to rate regulation would be charged to operations in the period that they were incurred.

The balance of the rate-regulated assets at March 31, 2007 were as follows:

Regulated Assets ($ millions)	March 31, 2007
Deferred taxes (Centra Gas)	$ 40
Site restoration costs	$ 38
Acquisition costs	$ 26
Power smart programs – gas	$ 11
Total	$115

Income Taxes paid by Centra Gas (July 1999) as a result of its change to non-taxable status upon its acquisition by MH were deferred and are being amortized on a straight-line basis over 30 years. Acquisition costs related to MH's purchase of both Centra and Winnipeg Hydro are also being amortized on a straight-line basis over 30 years.

Site restoration costs are deferred and amortized on a straight-line basis over 15 years.

5.4.2 Mitigation Costs

MH is party to a December 16, 1977 agreement also involving Canada, the Province of Manitoba and the Northern Flood Committee Inc., the latter representing the five First Nations in the communities of Cross Lake, Nelson House, Norway House, Split Lake and York Landing.

This agreement provides, in part, for compensation and remedial measures to ameliorate the impacts of the Churchill River Diversion (CRD) and Lake Winnipeg Regulation (LWR projects). Comprehensive settlements have been reached with all communities except Cross Lake. Expenditures incurred to mitigate the impacts of the CRD and LWR projects were $17.3 million during fiscal 2006/07 and, to March 31, 2007, $616 million had been spent in the effort. MH forecast to spend an additional $30.5 million in fiscal 2007/08 and a further $29.9 million in fiscal 2008/09.

In recognition of the anticipated future additional mitigation payments, the Corporation recorded a liability of $132 million as at March 31, 2007. Mitigation related expenditures are amortized over the remaining life of the Generation and Transmission assets to which they pertain.

MH has also entered into agreements with the Province of Manitoba whereby MH has assumed certain obligations of the province with respect to certain northern development projects.

To-date, MH has assumed obligations totalling $143 million and in return, Water Power Rental charges were fixed until March 31, 2001. The remaining liability outstanding as at March 31, 2007 was $13 million.

5.5 Future Changes in Accounting Standards

5.5.1 Adoption of International Financial Reporting Standards (IFRS)

The Canadian Accounting Standards Board (AcSB) has established that 'publicly accountable enterprises' (MH, including its subsidiaries, is such a body) are to prepare their audited accounts in accordance with International Financial

Reporting Standards (IFRS). In short, IFRS is to replace current Canadian Generally Accepted Accounting Principles (GAAP) and it is to be implemented effective January 1, 2011. As annual accounts are provided with comparative information for the previous year, MH will be required to also develop IFRS-based accounts as of fiscal 2010 – 2011, to be disclosed as comparative information when it files its 2011/12 accounts.

In advance of the adoption of IFRS, Canadian GAAP standards have changed for rate-regulated operations. Specifically, section 1100 General Accounting of the CICA Handbook will apply to the “recognition and measurement of assets and liabilities subject to rate-regulation” for fiscal years beginning on or after January 1, 2009.

MH stated that the interim changes to GAAP are not expected to have an impact on its fiscal 2008/09 or 2009/10 financial results and statements. MH has taken the position that it will continue to be allowed its current accounting practices for rate regulated assets through its adoption of a secondary source of GAAP found in US accounting standards, also related to accounting for regulated operations. The assets and liabilities subject to rate regulation pursuant to US accounting standards amounted to $115 million at March 31, 2007.

Yet, early adoption of IFRS is provided for by GAAP and, depending on the actions of the Board, may result in a change in accounting for rate-regulated assets ahead of the required adoption date for IFRS.

5.5.2 Future Financial Implications of Adoption of IFRS

MH indicated that the major implications expected from the adoption of IFRS are reduced annual and forecast net income and retained earnings as of the date of adoption. These impacts are due to “stricter” standards than now exist with Canadian GAAP as to what must be capitalized as opposed to what should be charged to operations in a given year.

Although the implications for MH are not fully known, there is a likelihood that IFRS will require MH to recognize a higher level of expense each year, and a corresponding lower level of costs will be deferred and capitalized.

The current version of the International Accounting Standard (IAS) 38 - Intangible Assets, on which IFRS is based, is much more comprehensive than current Canadian GAAP. In order for an intangible asset to qualify, it must be separable from the entity, such that it can be sold, transferred, licensed or otherwise disposed of to another entity. Also, in order to record an intangible asset, it must be probable that future economic benefits are attributable to the asset and will flow to the entity.

If regulatory assets and deferred pension costs are not allowed under IFRS, the deferred balances at the date of implementation will no longer be allowed to be presented on the balance sheet and will be deducted from Retained Earnings, restating retained earnings to a lower balance.

MH stated that the full impact that IFRS will have on MH financial statements is not known at this time, as IFRS accounting standards are still in the discussion stage, with some of the discussion centred specifically on the capitalization policies of rate-regulated enterprises.

A major matter of considerable potential importance to the issue of rates to be resolved is whether IFRS will allow capitalization and deferral of certain costs for recovery through rates over future periods, providing that the utility’s regulator assures that future rates will reflect the deferred or capitalized costs.

MH indicated that it would be engaging a consultant to guide the Corporation through the transition to IFRS, and expects to have a better idea by the fall of 2008 on what impacts IFRS will have.

As of yet, there had been no preparation of pro forma IFF modeling the potential impact of the new accounting standards. MH further indicated that while the Corporation has no present plan to make an earlier adoption of IFRS, this decision may be revised once the impact that IFRS will have on its financial reporting is known.

In particular, MH testified that certain of its current capitalization policies may be affected by IFRS, and that several types of currently-deferred charges may have to be expensed for accounting purposes in the year they are incurred, unless it can be demonstrated that the charges have a future benefit to MH, thereby satisfying the requirements of IFRS. Included in deferred charges are $115 million of charges related to rate-regulated assets, which may or may not have a basis for capitalization and deferral under IFRS standards. MH further indicated that deferred charges related to Planning Studies (current balance, $28 million) and the Affordable Energy Fund (current balance, $34 million) may also not meet the IFRS capitalization criteria.

Another specifically cited major impact of IFRS adoption will be on MH’s practices related to capitalized overheads, which are now in excess of $60 million annually. MH’s understanding is that overheads will have to be a direct charge to specific projects, and to continue MH’s current approach may involve undue administrative complexity. Potentially, the full $60 million of annual capitalized overhead could be charged against operations in the year incurred, under IFRS.

MH further indicated that the allocation of direct labour to capital projects also includes an element of overhead, which also could be in contravention of IFRS and require revision. MH indicated that such a change in this matter could result in an additional $20 million to $30 million of annual costs to be expensed rather than capitalized. (MH testified that its understanding is that overhead capitalized in the years prior to IFRS will not have to be written off, and that IFRS would be prospective rather than retrospective in this regard.)

MH also stated that its current accounting policy that amortizes experience gains and losses on the Employee Pension Plan may also be affected by IFRS, and will likely result in a one-time write-off of the then-current unamortized balance, now being approximately $30 million. The future impact on operating results and retained earnings with respect to this particular matter will depend on the experience of the pension fund to fiscal 2010 – 2011, and thereafter.

MH also stated that its capitalization of mitigation costs may also be affected by IFRS, in that although costs may still meet the standards for capitalization, the tests used to treat them as an asset may require a more direct correlation to a specific capital project than is currently used.

MH opined that its current deferral of Power Smart Programs ($123 million) can be demonstrated to have a future benefit (that being the intended and expected creation of increased export revenue) and thus, continued deferral may be allowed under IFRS. Natural Gas Power Smart Programs (Centra) were specifically identified as possibly not meeting IFRS capitalization criteria, and thus may require expensing in the year incurred.

Overall, MH advised that the changes expected to be brought on by IFRS may result in annual increases in operating expenses in the order of $100 million (now, the equivalent of a 10% rate increase for domestic customers). In addition, MH has reported a potential $100 million write-off of disallowed assets against retained earnings on implementation of IFRS (and this may prove a low estimate).

MH understands that the application of IFRS will generally be prospective but noted that there are certain electives for first time adopters of IFRS that allow a deemed approach to be used to value items such as property, plant and equipment. This, too, could involve adjustments to MH's accounts, including retained earnings.

MH advised it expected to have its consultant's advice by the fall of 2008, at which time a more definitive assessment of the impact of IFRS will be available.

5.6 OM&A Cost Control Process

MH utilizes a comprehensive budgeting process to establish and monitor its OM&A expenses. An IFF target is established through a top-down process whereby submissions are made to MH's Executive Committee for review and assessment of the amount of operating costs required to operate the utility.

The Executive Committee reviews requests and makes submission to MH's Board of Directors for approval of a final budget. Once approved, target levels are allocated to the business units, and business units prepare detailed operating plans. Business units are expected to review opportunities for both cost increases and decreases in their detailed budgeting process, and are required to submit that information to the Executive Committee to assist with the next year's target-setting process. Variance analyses are performed monthly to evaluate the performances of the business units.

MH advised that its forecast for annual OM&A incorporates a 1% productivity factor to its otherwise expected labour costs in each of the years. Labour costs represent approximately 75% of MH's OM&A costs.

In Order 07/03, the Board stated:

> "Corporate performance measures, such as the operating and administration costs per customer or per kW.h targets, are of great assistance in assessing the performance of MH's cost control initiatives compared to other utilities. The Board recommends MH aggressively pursue meeting its operating and administration costs-per-customer target while finding ways to increase productivity. The Board also encourages MH to continue to participate in benchmarking initiatives to help identify and implement further efficiencies and enhancements in its operations as compared to other utilities."

In its last three Corporate Strategic Plans (CSP), MH has outlined various strategies for improving productivity, including process benchmarking and the development of corporate and business unit performance targets. In the 2005/06 CSP, MH outlined two strategies for improving corporate financial strength: "leverage technology to reduce costs and the benchmarking of key corporate processes."

In the 2006/07 CSP, MH again outlined strategies for improving corporate financial strength, citing intentions to "leverage technology to reduce costs" and "benchmark against recognized service leaders". Yet, MH indicated at this GRA that it had not recently participated in any benchmarking exercises comparing its costs with those of comparable utilities.

In updating the Board on the status of these initiatives, MH stated that terms of reference and/or work plans have yet to be developed. MH conceded that work needed to be done in the area but stated that staffing resource limitations affect projects to be prioritized, and that benchmarking of processes was not of the highest priority level.

5.7 Intervener's Positions

The Coalition

The Coalition questioned whether MH had done what it said it would do to improve corporate financial strength. Mr. William Harper, a Coalition witness, expressed concern as to whether MH is undertaking everything it can do to identify and pursue productivity and efficiency improvements. Mr. Harper noted MH is forecasting an average annual increase in OM&A expense of 3.9% for the two year period fiscal 2007- 2009. Mr. Harper observed that the OM&A forecast of growth for this period was higher than reported in previous financial forecasts for the same period.

Mr. Harper further noted that the historical growth in OM&A over the last four years was 4% per annum. Looking forward, he noted that MH is forecasting annual customer growth of 0.6% per year, down from 0.9% historically, while wage and salary increases per FTE are also forecast to move down from 3.8% to 2.6%. Mr. Harper stated these two factors alone would suggest that OM&A spending over the two year period should be increasing significantly less than the 4% experienced historically, and less than the 3.9% increase proposed in the application.

Mr. Harper indicated that the potential annual savings related to a change in the expense growth factors would be $7 million in fiscal 2007/08 (the year finished before the hearing concluded) and $14 million in fiscal 2008/09, representing approximately a potential 1% reduction in rates.

Harper opined that overall projected OM&A cost for the periods through fiscal 2008/09 are too high and that a growth rate of 3% per annum (as opposed to the 3.9% forecast) would be more in line with the underlying cost drivers. Mr. Harper recommended the Board direct a reduction from the proposed rate increase of 2.9% (to 1.9%) to reflect this factor.

During the 2003-2007 period, MH's annual productivity improvement was reported to have been in the order of 1% per annum. However, during this period actual OM&A costs (when normalized on a per-customer basis) were generally higher than earlier forecasts and also higher than the annual CSP targets. Mr. Harper suggested that the evidence called for more discipline in the management of costs. Mr. Harper further stated that MH has consistently missed its CSP performance targets related to electric operations OM&A cost-per-customer. The OM&A cost-per-customer target for fiscal 2007/08 was $640 per customer; he suggested setting rates to match this target would reinforce the message that OM&A must be managed within expectations.

Mr. Harper suggested that productivity improvements cannot occur without action, and that what was required is an environment where opportunities for such improvements can be identified and staff encouraged to aggressively pursue them.

Mr. Harper noted that while appropriate strategies have been articulated in the CSP (such as leveraging technology to reduce costs and benchmarking key corporate processes against recognized service leaders), these steps have not been undertaken, and with respect to benchmarking, Mr. Harper noted that MH has indicated not having participated in any formal benchmarking exercises comparing its costs to those of comparable utilities. And similarly, that there has been no formal benchmarking process undertaken, even though the strategy has been articulated in prior corporate strategic plans over the last few years.

In the area of corporate and business unit performance measures, the Corporation has yet to develop a term of reference of work planned for this initiative, and Mr. Harper stated that MH should be encouraged to follow through on the strategies with a view of ensuring that the 1% per annum productivity improvement is actually achieved, if not exceeded.

The Coalition stated that given the large number of pending major new projects, it would be difficult for MH to balance priorities. The Coalition stated it was important for MH to get the "fundamentals" right, and that benchmarking has not been seen as a high enough priority for the Corporation.

The Coalition also cited the concerns raised by Mr. Bowman, a witness for MIPUG, about the divergence between forecast and actual OM&A results, a divergence that undermines the achievement of financial targets. The Coalition noted Mr. Bowman's' observation that systematic increases in OM&A spending have been a consistent and compounding reason underlying MH's failure to achieve the debt:equity target of 75:25.

The Coalition noted an example from its review of IFF05-1, where the forecast cost per customer in fiscal 2009 was $338 and that by IFF-07-1 the forecast costs per customer for the same year had increased to $360. The Coalition seconded Mr. Bowman's observation that this negative trend threatens to undermine the achievement of MH's financial targets.

With respect to the upcoming adoption of IFRS, the Coalition supported MH's position that it was premature to reach any conclusions on the impact at this time.

In supporting Mr. Harper's recommendation for the Board to reduce MH's requested revenue increase by 1%, the Coalition observed that while, at least in the short term, granting less than the requested rate increase might appear to be counter-productive to the goal of achieving financial targets, for the Coalition the short-term “pain” would likely prove beneficial in the longer term.

Reducing the requested rate increase would still leave the option for MH to put forward an application in 2009 or 2010 demonstrating improvements in cost control, and seeking increases in the revenue requirement once new capital expenses are projected and the Corporation has more certainty about the financial impact of the adoption of IFRS.

Mr. Harper suggested OM&A expenditures be evaluated on four criteria.

1. A review of cost elements, focusing on those that have changed significantly from one year to the next, to test the reasonableness of the underlying changes.
2. Evaluation of key cost drivers; with variations to be explained on the basis of unique or one-off requirements.
3. Benchmarking of the specific activity costs of the Utility against other utilities of similar characteristics.
4. Review of utility spending plans and priorities, incorporating an evaluation of an Asset Condition Assessment, to support any proposed increased spending. An Asset Condition Assessment (ACA) would, according to Mr. Harper, provide a “snapshot of the utility’s assets, noting the degree of degradation and need for rehabilitation and replacement”. For Mr. Harper and the Coalition, MH should be required to demonstrate that the condition of the assets has changed such that additional spending is required.

MIPUG

MIPUG also noted that MH's OM&A forecasts have progressively increased since the 2002 Status Update review, and that the Corporation's actual spending also routinely exceeds forecasts.

MIPUG noted that the growth in the level of OM&A spending has occurred despite prior Board directives for MH to consider cost control initiatives, citing that recently the Board noted in its decision with respect to MH's interim 2007 rate increase that it "…relies on MH's Board of Directors and senior management to continuously strive to operate the utility efficiently and incur no material costs that are not warranted from the perspective of sound business practices".

MIPUG submitted that MH's evidence in the proceeding did not support the conclusion that MH's OM&A spending is at levels consistent with an efficient operation. For MIPUG, this is particularly true when viewed in the context of forecasts prepared in recent years, as noted in some detail in the evidence of the Coalition's witness Mr. Harper which indicates increasing levels of spending.
