Executive Summary

A. Overview

Manitoba Hydro is seeking government approval of its preferred development plan for investments in generation and transmission capacity in order to support domestic load growth and expand opportunities in export markets.

The Manitoba Public Utilities Board ("PUB") was asked by the Government of Manitoba to conduct a Needs For and Alternatives To ("NFAT") review of the Manitoba Hydro development plan. A panel of PUB members ("the NFAT Panel") was selected by the PUB Chair to conduct the review. In order to proceed with its review, the NFAT Panel will use evidence presented by Manitoba Hydro, interveners, and independent experts provided by PUB. Potomac Economics is one of the PUB independent experts and our report addresses expected export market conditions in the markets administered by the Mid-Continent Independent System Operator ("MISO"). The MISO markets are the primary source of export revenues for the preferred development plan.

Potomac Economics is the Independent Market Monitor for the MISO. In this role, we closely monitor prices, investments, market structure, and market outcomes. We are also the Independent Market Monitor for ISO-New England, the New York ISO, and ERCOT (Texas). We rely on this broad experience with the development and performance of wholesale electricity markets to conduct this study.

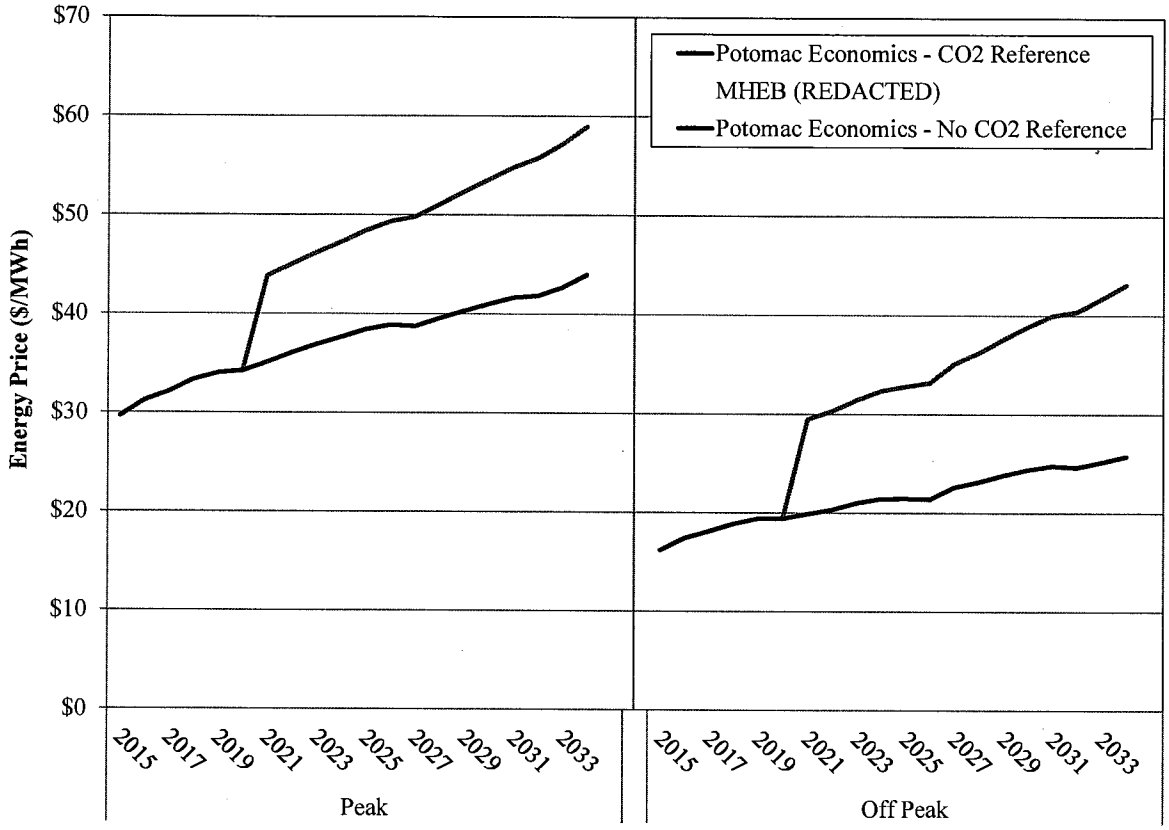
Manitoba Hydro's preferred development plan establishes generation capacity which exceeds the projected domestic load requirements for a significant period of time. The excess capacity, along with other investments in the plan to expand transmission ties to the US, would support export sales. According to the plan, by building larger plants and using the excess capacity to support export sales, the cost of meeting the growing domestic load in Manitoba is lower than if capacity was built to meet load growth alone. The preferred development plan is expected to deliver the expected benefits if actual conditions meet certain critical projections. Among these critical projections is the revenue that can be earned from sales of energy and capacity to the MISO markets in the US. These revenues are based on export price forecasts from six consultants

retained by Manitoba Hydro. Our report assesses the price forecasts and other associated issues that form the basis for Manitoba Hydro's projected MISO export revenues.

In order to assess Manitoba Hydro's price forecasts, we developed our own price forecast based on a method and approach that we find to be a reasonable and transparent. Our method is based on forecasts of key drivers of MISO market prices. These key drivers are fuel prices, load growth, generation retirement and additions, new-build generation capital and operating costs, environmental regulations, and congestion.

Manitoba Hydro's six consultants based their forecasts on essentially the same key drivers. However, we believe certain assumptions made by the consultants tended to overstate the level of future prices. Due to limits on the availability of the underlying data from the consultants' models, we were not able to perform a detailed review of the consultants' models nor could we adjust the specific assumptions in the consultants' forecasts to address differences. As result, we provide an alternative forecast and recommend that these forecasts be used to assess revenues projected under the development plans.

B. Summary of Results



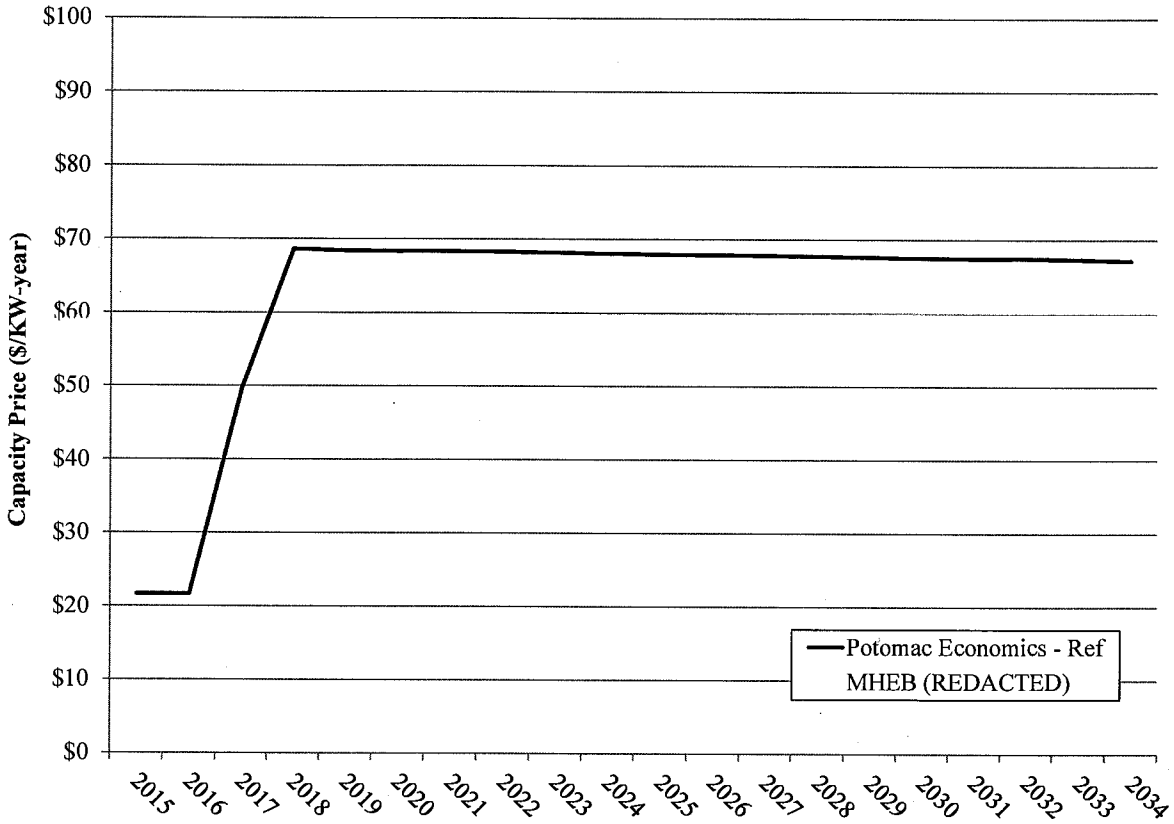
Our forecast is based on MISO supply and demand characteristics and recent market outcomes. Changes in these characteristics and outcomes are forecasted for future years based on assumptions regarding the evolution of key drivers noted above.

Our results generally forecast lower prices than Manitoba Hydro's consultants due to assumptions on key inputs. In particular, our models generally rely on lower natural gas price forecasts, lower growth rates of demand, and lower quantities of coal plant retirements. As explained herein, our point-of-view on these key assumptions is based on the reference case used by the US Energy Information Agency (EIA) in its 2013 Annual Energy Outlook.

Figure 1 shows our two reference case forecasts for on-peak energy and off-peak energy prices compared to the Manitoba Hydro reference price forecasts. Manitoba Hydro's reference price forecast is the composite of its six consultants' forecasts. We produce two reference case forecast in order to reflect two CO2 price scenarios – one scenario is based on the reference

forecast of Mr. Craig Sabine of MNP, and the other is a reference case with no CO2 costs. We explain these various cases in Section II.

Figure 1: MH and Potomac Economics Reference Case Energy Forecasts



As the figure shows, the Manitoba Hydro forecasts [redacted] for both on-peak and off-peak energy prices, although our reference forecas[redacted] [redacted] forecast period for on-peak energy. In this report, we will explain how we developed our price series and why they are different from the Manitoba Hydro prices.

We also forecast capacity prices, which are based on our estimate of the net cost of new entry ("net CONE"). We assume that when surplus capacity dissipates, the capacity price will rise to the level necessary to incent the construction of new resources. As we explain herein, this capacity price is at most the net CONE of a new peaking resource, which is equal to the resource's cost of new entry less the variable profit it would earn in the MISO's energy and ancillary services markets. However, in the short-run, we do not expect the market to support

the net CONE. Figure 2 shows the comparison of our reference case capacity price forecast and Manitoba Hydro's forecast.

Figure 2: MH and Potomac Economics Reference Case Capacity Forecasts

As the figure shows, our price [redacted] estimates by Manitoba Hydro. The main reason for this is our assumptions regarding the cost of new entry. Our assumptions regarding the costs to build an advanced combustion turbine [redacted] that assumed by Manitoba Hydro consultants. We note that the capacity prices that we forecast [redacted] han that which Manitoba Hydro can actually achieve, due to regulatory and other constraints, discussed herein.

We present forecasts for energy and capacity prices under four scenarios that examine alternative assumptions. In addition to our two reference cases, we examine alternative assumptions concerning natural gas prices and economic growth. Changes in these assumptions can substantially affect Manitoba Hydro's forecasted revenues.

C. Organization of Report

We were asked by the PUB to provide an Independent Expert Report on MISO market conditions that Manitoba Hydro will face under its proposed development plan. Because the critical factor in the MISO markets is prices, the main part of our report is in the following three sections:

Section I discusses the price forecasts used by Manitoba Hydro;

Section II presents our own forecasts for energy prices; and

Section III presents our own forecasts for capacity prices.

In addition to assessing the price forecasts, we also assess issues associated with other expected market conditions that affect future export prospects. These other issues include: (2) developments in neighboring regions; and (3) export volumes and pricing. These other issues are discussed in Section IV.

I. THE CONSULTANTS' PRICE FORECASTS

Manitoba Hydro used six external consultants to produce price forecasts for its financial model. These six forecasts are used on an equal-weight basis to establish a single consolidated forecast. In this section, we review and discuss the six forecasts.

A. Products

The company expects to sell an on-peak energy product, an off-peak energy product, and a long-term "dependable" product. The on- and off-peak products are assumed to be priced based on the consultants' on- and off-peak price forecasts. The long-term dependable product is assumed to include a capacity component. Accordingly, Manitoba Hydro asked the consultants for 20-year forecasts for the period 2015-2034 for on-peak energy, off-peak energy, and capacity prices.

B. Summary of Consultants' Forecasts

The six consultants use variations on a common approach to forecast energy prices. The approach uses a so-called "fundamentals" model that basically attempts to simulate the energy dispatch of the electrical system to determine which units are on margin during each hour of the year. The hourly prices simulated for on-peak periods are the basis for the on-peak prices and the hourly prices simulated in the off-peak periods are the basis for the off-peak prices.

The consultants generally use the forecasted energy prices and the estimated cost of new entry for a new peaking resource to forecast capacity prices. In particular, the forecasted capacity price in each year is generally equal to the annual fixed cost of new entry less the anticipated "net revenues" earned by a peaking unit. Net revenues are the revenues a unit would earn in MISO's energy and ancillary services market in excess of its variable production costs. This net revenue approach is a reasonable way to forecast the capacity price. It is important to recognize that the MISO does not currently have a well-functioning capacity market that would establish prices consistent with this net revenue methodology. Nonetheless, one may assume that Manitoba Hydro may be able to sign bilateral contracts to sell capacity at these price levels to load-serving entities in MISO that would otherwise be short of capacity. There is some uncertainty about this assumption which is discussed in Section III.

The following is the list of consultants and the summary of the results of their analysis and our discussion of their process and results. The consultants each provided forecasts of off- and on-peak energy prices and annual capacity prices. The consultants provided a "reference case" and most consultants provided a "low" and "high" case. Our discussion of the consultants' models is confined to the on-peak energy price and the capacity prices associated with the "reference case." The issues identified with the reference case also tend to adversely affect the consultants "high"- and "low" cases in comparable ways. Similarly, the problems we see with the on-peak energy price estimates, also affect the off-peak estimates in the same manner. Therefore, we focus on the areas of concern associated with the reference case for on-peak energy and capacity.

At the outset, we note that detailed information regarding each of the consultants' models, assumptions, and output was limited. We generally only received high-level representations of the models and inputs. This limited our ability to critically review the consultants' results and ultimately compelled us to produce our own forecast. Nonetheless, we briefly summarize each of the six consultants' forecasts in the following subsections.

1. The Brattle Group

The Brattle Group forecasts reference case on-peak energy prices in the near term just under $40/MWh until about 2020, then increase to over $60/MWh by the end of the 20-year forecast period. As indicated above, the forecast is based on a simulated dispatch of the system using a variety of assumptions. Given our limited information regarding the model and assumptions, it is not straightforward to determine exactly what drives the price forecast. However, we note three key assumptions used by the consultant (and which generally are the key assumptions used by all of the consultants). The first is the assumed introduction of carbon taxes in 2020. This starts at $15/ton and grows until 2034 to about $24/ton. The second key assumption is the increase in the price of input fuel -- natural gas prices increase by 60 percent over the 20-year period. This has an impact on the on-peak price directly, but is also interconnected with the third key assumption, which is the retirement of coal plants. Lower coal capacity causes natural gas-fired units to be on the margin in more hours. Both the additional hours on the margin and the higher natural gas prices will cause energy prices to be higher. Brattle did not report MISO-wide retirements in its work papers. It reports MRO-West retirements because its forecast model focuses on the MRO West sub-region of MISO. However, a report by Brattle in 2013 indicates

between 11 and 16 GW of MISO coal plant retirements. This level of MISO coal plant retirements is substantially above the level we assume in our reference case. As explained below, we assume 6 GW of MISO-wide coal plant retirements. The emissions and fuel cost assumption along with the high level of coal plant retirements are likely to overstate energy prices.

Capacity prices are based on the least-cost capital investment needed to meet planning reserves over the 20-year horizon. The annual fixed cost of this investment (primarily capital carrying costs) net of revenues earned in the energy markets, establishes the capacity price for each year. This is affected primarily by the energy price forecast and the net retirement, but also capital costs of new facilities. As a noted above, this approach assumes Manitoba Hydro will sell capacity to utilities in MISO on a bilateral basis to meet the utilities' planning reserve requirements, rather than selling in the short-term capacity market presently existing in MISO.

Capacity prices estimated by Brattle are zero until 2019, reflecting an assumed capacity surplus in MISO until that time. After 2019, the price rises to over $70/kW-year. The Brattle work papers do not specify what type of unit is setting the capacity price in a given year. However, the capacity price is consistent with the capital cost identified by the consultant for both the natural gas-fired combustion turbine and the natural gas-fired combined cycle plant ($1200/kW net of modest energy market revenues). Both the CT and the CC are assumed to have capital cost of about $1200/kW, which is roughly $120/kW-year in carrying and fixed costs. The lower value of $70/kW-year could reasonably reflect variable profits in the energy markets.

[redacted]. In particular, the consultant assumes a cost of $1200/kW for a CT, whereas the EIA has identified an advanced CT as having a capital cost of approximately $700/kW. This would have a significant effect on the consultant's capacity prices. EIA's estimate of the advanced combined cycle plant ($1000) and the conventional combined cycle plant ($900/kWh) are also somewhat lower than the estimated cost used by the consultants.[1]

[1] See, EIA, "Updated Capital Cost Estimates for Utility Scale Electricity Generating Plants", April 2013, http://www.eia.gov/forecasts/capitalcost/pdf/updated_capcost.pdf

We believe the emissions and fuel cost forecasts assumptions may overstate the expected cost profile of fossil-fuel fired resources and, thus, overstate energy prices. This may also understate capacity prices since net revenues would likely decline under a projection of lower energy prices. But this effect is confounded by the apparent overstatement of generator capital costs. Based on the information provide, we are not able to disentangle these countervailing effects and so we cannot recommend using the Brattle estimates as a basis of future prices.

C. Conclusions on Consultants' Price Forecast.

In general, the key assumptions used by the Consultants [redacted] This is particularly the case with respect to (1) natural gas prices, load growth, coal retirements, and cost of new entry. With respect to CO2 prices, our reference case assumptions tend to be [redacted] We explain our forecasting approach in the next section. In the Tables below, we compare our forecasts to the consultants.

The Table below shows a comparison among the six consultants along with our own forecasts of (1) on-peak energy; (2) off-peak energy; and (3) capacity.

D. Composite Forecasts and Alternative Cases

Manitoba Hydro used the consultant's price forecast to create a single composite forecast, which is basically an average of the consultants' forecasts. The following three charts show the composite price forecasts for the three power products (1) on-peak energy; (2) off-peak energy; and (3) capacity. In each case, we show the Manitoba Hydro composite forecast the consultants' reference case as well as the composite "high" and "low" forecast cases. We also show our reference case and the "high" and "low" alternatives for each forecast.

The low and high case alternatives were produced by each consultant at the request of Manitoba Hydro. Manitoba Hydro required plausible scenarios that could represent the lower and upper limits of pricing trends. While we also produce two alternative cases, our cases are based on likely alternatives that together with the reference case, represent a large range of probable outcomes. In other words, we expect that future prices are very likely to fall within the bounds of our three forecast scenarios.

II. POTOMAC ECONOMICS ENERGY PRICE FORECAST

Because detailed information regarding the consultants' models, input data, and results was not available to Potomac Economics, we evaluated their reasonableness by comparing their forecasts to a range of forecasts we developed. This section of the report describes our methodology and provides a detailed discussion of the results.

A. Overview of Forecast Model

Our forecast is based on historical publicly-available market outcomes in the MISO markets for 2011 and 2012. Our approach uses these actual day-ahead market results and adjusts them to anticipated changes in future market conditions, such as fuel prices, capacity, carbon taxes, and load growth. The MISO market data we use includes hourly data on system load and capacity, system marginal price, and supply offers. The day-ahead supply offers specify offer price, offered quantity (MW), fuel, and whether the offer was accepted. By stacking the offers in accordance with energy offer price we establish an hourly supply curve. We adjust the hourly supply curves to account for changes in fuel costs, new capacity additions and retirements, and carbon taxes. Hence, we establish a supply curve for all future hours in the twenty-year forecast horizon (2015-2034). Using actual hourly generation demand and assumptions regarding the growth of load, we establish forecasted load in every hour of the forecast horizon. Based on the intersection the hourly supply curve and the hourly system load (along with some operational adjustments described below), we can establish a system marginal price for each hour of the twenty-year forecast period. These hourly prices are the basis for our on-peak and off-peak energy prices.

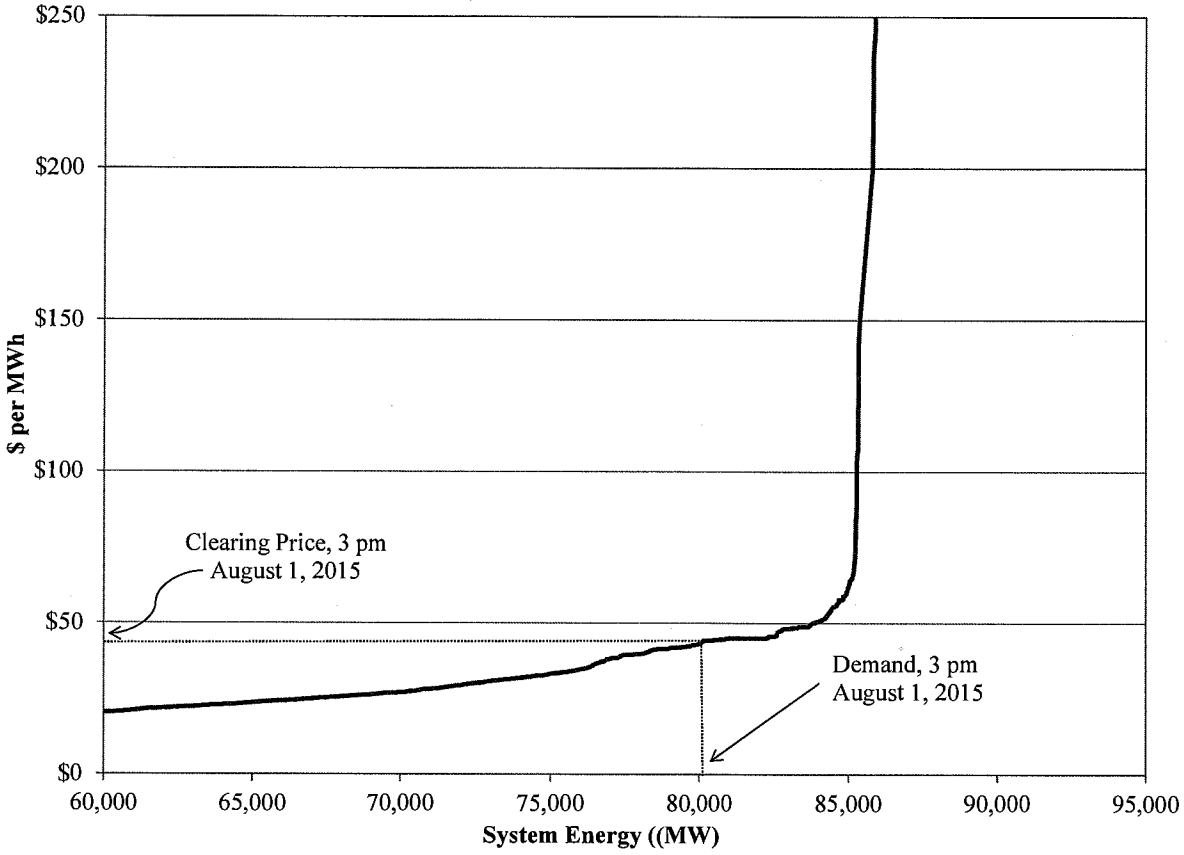
Locational Marginal Prices. The prices estimated using the hourly supply curves are the system marginal prices ("SMP"). They do not reflect the locational marginal prices (LMP) that would be received by a seller of power at various locations in MISO. Congestion and marginal losses will cause a locational price to be different from the SMP. Therefore, we compute a locational marginal price at the Manitoba interface with MISO by subtracting losses and congestion costs from the SMP. Congestion costs are estimated based on the historical relationship between congestion and factors that tend to explain their level, such as time of day, generation, load

levels, and exports from Manitoba Hydro to MISO. We use the historical average marginal losses as the estimate of future losses.

Capacity Prices. Capacity prices are estimated based on the net cost of new entry (net CONE). This net CONE is the annual carrying cost and other fixed cost of a new combustion turbine less the variable profits earned in the MISO energy and ancillary services markets. Based on the heat rate of a new combustion turbine (CT), any hour when the SMP is above the variable energy cost for the CT, the difference in marginal energy cost and the LMP is the net revenue for that hour. The resulting total net revenues are deducted from the annual fixed cost of the new unit to arrive at the estimated capacity price. The estimated price is the amount an investor would need to be paid to profitably enter the market with the prospect of earning MISO energy and ancillary services revenues. However, this price is relevant only if capacity is needed. In times of capacity surplus, the capacity price is likely to be less than this price and, indeed, sometimes close to zero. This presents a substantial risk for Manitoba Hydro that its capacity revenues may be much lower than expected.

B. Specifics of Forecast Model

1. Hourly Supply Curves and Demand



Our forecast model uses two years of historical MISO market data and creates two forecasts for each hour for the forecast period 2015-2034. There are two forecast for each hour, one based on 2011 hourly market data and the other on 2012 hourly market data. We average the two forecasts to get the forecast for each future hour.

For each historical hour, the day-ahead MISO data contains an offer curve for each resource that indicates the quantity, fuel type, and offer price (for start-up, energy, and ancillary services). We use these offers to establish an hourly supply curve for each historical hour, which is a simple stack of the MW offers in ascending order of offer price for each MW block.

We next use hourly generation demand to identify where system demand intersects the historical supply curve for each historical hour. Hourly system demand also is publicly available from MISO. It contains day-ahead system demand as well as net imports so that we can identify the hourly load that was served by the available supply in each historical hour. Comparing the

hourly load level to the supply curve identifies which unit would supply the last MW of load under the assumption that all units are dispatched fully.

Figure 9: Supply Curve for August 2015

Note: The "clearing price" shown is the basis of the forecast SMP. To arrive at the SMP, the clearing price is increased to reflect operational issues. This increase is derived from the historical clearing price and the historical SMP for each hour.

This marginal unit representing the direct intersection of the hourly supply curve and the hourly load is not likely to be the one that actually sets the system marginal price. This is because of operational constraints. Operational constraints occur as a result of constraints in the operation of generators. There are a number of operating constraints that may cause the strict stacking of units from low to high marginal cost not to match the actual dispatch. First, units may not be fully dispatched due to ramp limits in a given hour. In such a case, units may be dispatched at a higher or lower output level than would be indicated by running costs alone. A high cost unit may also be running because it is meeting a minimum run time. Such a unit may be more expensive than other units not fully running because the more expensive unit is needed in some

future hour and needs to be started in advance. Or the more expensive unit was needed in a recent hour and needs some time to turn down or turn off.

In each hour, MISO publishes the day-ahead SMP. With the SMP we can identify the unit that sets the marginal price on the historical hourly supply curves. Because this is rarely the unit that would clear in a "pure" sense from stacking the units against demand, in each historical hour we measure the movement up the supply curve that was necessary for MISO to undertake to dispatch the system in that hour given the operational restrictions it must accommodate. This value is expressed as a percentage increase in the energy "clearing" price. We retain this value, which we call the hourly "operational adjustment," because it is important for estimating the market clearing price for future periods.

2. Clearing the Hourly Forward Market in Future Hours

To clear the hourly market, and establish the forecast price for that hour, we adjust each historical hourly supply curve based on anticipated changes in key supply variables (fuel costs, etc.). We explain the evolution of the supply curve over the time horizon below. We also assume load grows at certain rates. Hence, in every future hour, we have (1) the estimated forecast hour supply curve; (2) the forecast hourly load; and (3) the "operational adjustment" (based on historical movement along the supply curve to clear the market, described above). Matching the estimated supply curve to the forecast demand for each hour, we identify the marginal unit in a "pure" market clearing. We then adjust the forecasted price by a percentage amount equal to the "operational adjustment," discussed above, to account for operating constraints. The resulting price is the forecast SMP for that hour.

3. Formation of Supply Curves

The process of clearing the hourly market described in the previous subsection is based on estimated supply and demand. The estimated supply curves for future hours evolve from the historical supply curves. If all key supply variables remained fixed, then the forecast of each future hour would be identical to the base historical hours from 2011-2012. However, of course, key variables change. In particular, we create new supply curves for each hour based on projections of (1) fuel prices; (2) additions and retirements of generating capacity; (3) load growth; and (4) carbon taxes. In addition, we make assumptions about the cost of new capacity

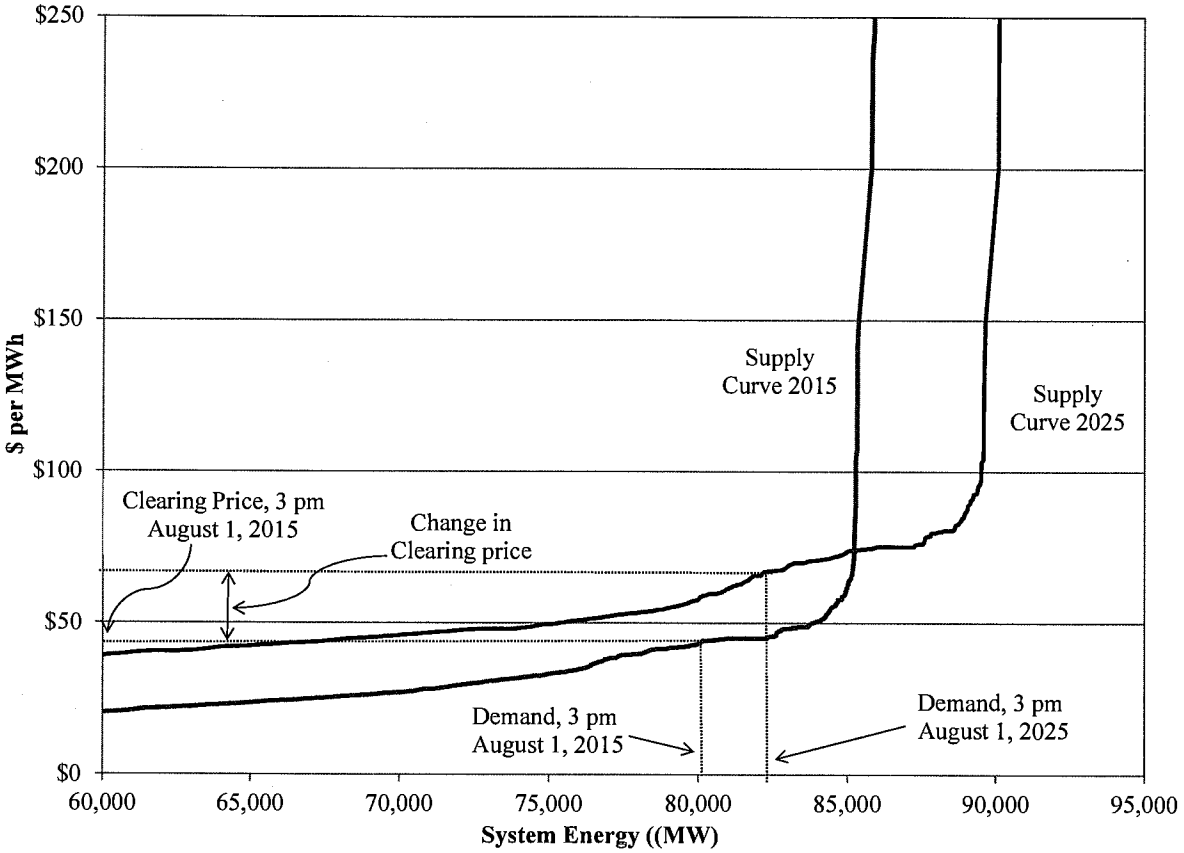
in order to estimate the cost of new entry to support the capacity price forecasts. We discuss the particular projections of these key assumptions in the next subsection. In this section, we describe how the supply curves change as a result of the key assumptions.

Fuel Prices. When fuel prices change, the marginal cost of producing energy from a resource using that fuel will change. In a competitive market, suppliers submit offers that are consistent with their marginal costs. Therefore, the offer prices of the unit will change as fuel prices change. Hence, each hourly supply curve in a given year will change based on the change in fuel prices for that year compared to the historical year.

CO2 Prices. CO2 prices are projected for potential changes in law regarding green-house-gas emissions.[2] CO2 prices are based on cost per ton of CO2 output. Coal and natural gas have specific CO2 content. According to the US EPA, Average CO2 output of a coal unit is 1.02 (metric)\tons/MWH and for a natural gas units about 0.516 tons/MWh.[3] This emissions rate is multiplied by the CO2 price forecast for each year to estimate the additional cost to be added to the unit's offer curve. For example, the CO2 price in 2021 is projected to be $13.14/(metric) ton. Therefore, offer curves for coal units have an increased incremental energy component of $13.14/ton x 1.02/tons/MWH = $13.40/MWh. For natural gas units, their incremental energy offers increase by $13.14/ton x 0.516/tons/MWh = $6.78/MWh.

Generating Resources. The historical supply curves for each hour are based on units that are in-service during that particular historical hour in the 2011-2012 historical years. In each subsequent year, the set of in-service units changes based on assumptions regarding *new* additions and retirements. This can result in a re-ordering of the capacity in the supply curve through "re-commitment" discussed in the next subsection. Our base assumptions regarding additions and retirements are based on the EIA Annual Energy Outlook assumptions.[4] We adjust these assumptions as needed to satisfy MISO's resource adequacy needs. When additional

2 We adopt the CO2 prices developed by Independent Expert Consultant Mr. Craig Sabine of MNP.



3 See EPA, http://www.epa.gov/cleanenergy/energy-and-you/affect/air-emissions.html

4 See, http://www.eia.gov/forecasts/aeo/data.cfm

resources are needed, we assume one-half of the new resources are combined cycle natural gas units and one-half are natural gas combustion turbines.

When the EIA data indicates retirements of a unit type for a specific year (e.g., coal units), we choose units to retire based on units net revenue for the previous year. The least profitable are retired first.

Figure 10: Example of Change in Supply Curve

Note: The figure shows the change in forecast clearing price in our model resulting from changes in supply and demand between 2015 and 2025.

4. "Headroom" and Daily Recommitment

The supply curve for each future period also is adjusted to reflect the fact that future periods will have different supply and demand characteristics due to changes in key drivers, mainly load and the composition and quantity of available generating capacity. The supply curve for a historical hour is based on the historical load and the commitment of units in service at the time. When load changes in a future hour, it is not reasonable to simply move along the historical supply

curve to a new load level to clear the market for that future hour. Instead, at a new load level, some units that were not committed in the historical hour may be economic for commitment at a higher or lower load level and therefore be added to the supply curve. This type of recommitment may also be appropriate if new units are added or existing units retire - these new units may replace existing units in the stack or existing units not initially committed may replace retired units in the stack.

In order to recommit generation, we seek to ensure the system has adequate resources to meet forecasted load, ancillary services, and the market headroom requirement (the headroom requirement is the additional operating flexibility required by RTOs to meet ramp demands). Much like MISO's day-ahead market, our process for re-committing resources is performed on a daily basis. If headroom is inadequate in some hour, the daily commitment is revised to ensure that sufficient generating capacity is available for dispatch.

The revised commitments are is then used as the basis for the hourly supply curves for that day and the market is cleared in accordance with the process described above.

5. Reference Forecast Assumptions and Alternative Cases

We develop forecasts under three alternative scenarios. Each differs from the other according to different assumptions on key supply and demand inputs. As we discussed above, aside from the historical MISO data that form the base case supply curves, a price forecast depends on assumptions about (1) load growth; (2) fuels costs; (3) retirements and additions; (4) CO2 prices; and (5) cost of new generation (for capacity prices). Our three scenarios are as follows:

a. Reference Cases

We use two reference cases due to the significant uncertainty regarding the introduction of CO2 costs. We develop a first case, called simply, the "Reference Case," which includes positive CO2 costs. Our "Reference No Carbon" case is very similar to the reference Case except CO2 costs are zero, and the load growth is slightly higher.

Both the Reference Case and the Reference No Carbon case are based on the assumptions used by the EIA in its 2013 Annual Energy Outlook for its own reference case. The EIA reference

case assumes CO2 costs are zero. Therefore, the EIA reference case assumptions on load, capacity, and fuel prices are used in our Reference No carbon Case.

For our Reference Case (with Carbon), we depart from the EIA reference case in order to reflect CO2 prices. We introduce a CO2 price in 2021, consistent with the forecast of Mr. Craig Sabine of MNP who is the Independent Expert Consultant for the PUB in this NFAT on matters relating to CO2 pricing. According to Mr. Sabine's reference case, the CO2 price will be zero until 2021, at which point it will be $13.14/ton and increases by 5 percent per year thereafter. We reflect Mr. Sabine's forecast by adjusting offer curves for fossil fuel plants to account for the additional CO2 cost. The adjustment to offer curves to reflect this additional cost was described above.

We also slightly reduce the EIA Reference Case load growth starting in 2021 to reflect non-zero CO2 prices starting in year 2021. In particular, for the years 2015-2021, we use the compound average growth rate (CAGR) from the EIA reference case for those years. Starting in 2022, we adopt the load growth rates envisioned by EIA under a $10/ton CO2 price ("EIA GHG10"), wherein the EIA assumes a 2014 CO2 price of $10/ton. We use the CAGR from EIA GHG10 for the years 2015-2034 for our years 2022-2034 in our reference Case. We use the earlier years in the EIA GHG10 to match the growth rates that would be expected once the non-zero CO2 prices are realized (assumed to be realized in 2021 in our Reference Case).

For both of our reference cases, fuel prices were taken directly from the EIA reference case -- Henry Hub for natural gas prices and Wyoming Powder River Basin for coal. We assumed a further coal transportation cost into MISO of $1.7/MMBTU, a value typically used in the MISO to account for coal transportation. Natural gas transportation costs are assumed to be $0.75/MMBTU. Generation retirements and additions are taken directly from the EIA reference case. We began 2013 with a MISO capacity surplus of 6,200 MW.[5] When load growth together with net capacity retirements resulted in a year with a capacity deficit, some future EIA reference case additions were moved forward or additional natural gas capacity was added beyond that scheduled in the EIA reference series. These key input series are shown in Appendix A.

[5] See Potomac Economics, "2012 State of the Market Report for the MISO Electricity Markets", p. 18, figure 8. It shows a capacity market surplus for July 2012 of 6200 MW.

For each year, we simulate the SMP for all hours using the historical supply curves adjusted for the assumptions of this case. For the 16 peak hours of each (non-holiday) weekday, we calculate the average SMP to establish the on-peak SMP for that hour of that year. The average price for all other hours establishes the off-peak SMP for that hour of that year.

b. High Resource Production (Low Fuel Price) Case

We believe a credible case is one in which natural gas prices may show little change over the next 20 years. This is credible because of the additional natural gas supply that has been made available through hydraulic fracturing technology, which has already been shown to increase natural gas production in North America. Accordingly, we produce a price forecast using the assumptions associated with EIA's "High Oil and Gas Resource" case, which models the effect of high resource production on fuel prices and the secondary effects on electricity markets.

For load growth in the High Resource Case, we used the levelized growth rate of load for the 2015-2034 period used in EIA's High Resource case. We assume no CO2 costs for this case. Fuel prices were taken directly from the EIA High Resource case (the Henry Hub natural gas and Powder River Basin coal prices).

Generation retirement and addition assumptions are taken directly from the EIA High resource case, but adjusted to ensure that MISO's resource needs are satisfied. Like our reference case, we began 2013 with a MISO capacity surplus of 6,200 MW. When load growth together with net capacity retirement resulted in a year with a capacity deficit, some future EIA reference case additions were moved forward or additional natural gas capacity was added beyond that scheduled in EIA High Resource series. These key input series are shown in Appendix A.

c. High Economic Growth Case

We also believe there is a significant likelihood that economic growth may be higher than assumed in the EIA reference case. Accordingly, we produce a price forecast using the assumptions associated with EIA's "High Growth" case, which models the effect of higher macroeconomic growth on electricity markets. We assume CO2 cost in accordance with the reference case developed by Mr. Sabine (the same CO2 costs as in our reference case above), which start at REDACTED . For the

years 2022-2034, load grows more slowly than in the EIA High Growth case. We assume a lower growth rate in later years to reflect the effects of the CO2 costs. In particular, the growth rate is the average of (1) the levelized growth rate in the EIA High growth case for 2022-2034 and (2) the levelized growth rate in the EIA GHG10 case for the year 2015-2034.

Fuel prices were taken directly from the EIA High Growth case (Henry Hub natural gas and Powder River Basin coal).

The quantity and timing of generation retirements and additions are taken directly from the EIA High Growth case, adjusted as needed to satisfy MISO's resource needs. Like our Reference Case, we began 2013 with a MISO capacity surplus of 6,200 MW. When load growth together with net capacity retirement resulted in a year with a capacity deficiency, some future EIA High growth case additions were moved forward or additional natural gas capacity was added beyond that schedule in EIA High Growth series. These key input series are shown in Appendix A.

C. Estimates of Losses and Congestion

The previous section described the forecast of the MISO System Marginal Price, which is the underlying commodity price throughout MISO. This price does not include the effects of losses or transmission that can cause locational marginal prices ("LMPs") at a location to be higher or lower than the SMP. Manitoba hydro will settle its energy imports at the Manitoba interface location. Therefore, we forecast the losses and congestion that will be incurred at the Manitoba interface relative to the SMP. We use the historical relationships in the 2011 and 2012 data to forecast future losses and congestion.

1. Losses

For losses, we use the average observed marginal losses calculated by MISO over the two year period 2011-2012 as the marginal loss factor going forward. We do not believe there are any currently known changes to the system that would raise or lower losses significantly going forward. For on-peak hours, we assume an average marginal loss factor of 8.8 percent. For off-peak hours, we assume a marginal loss factor of 9.4 percent.

2. Congestion

Unlike losses, transmission congestion can change substantially as the dispatch of the system or the topology of the network changes. To forecast congestion, we develop an econometric model to estimate how key factors will affect congestion. We use standard linear regression techniques to develop this model. The estimated relationship is then used to forecast the future value of congestion based on projections of future key variables. The results of this estimated model, along with the standard statistical diagnostics, are provided in Appendix B.

We use the hourly data from 2011-2012 and hypothesize that congestion depends on a number of "explanatory" variables. These variables include:

System Marginal Price. The system marginal price is the price calculated by MISO that represents the marginal cost of meeting the next increment of load in MISO. We hypothesize that a higher SMP will result in higher congestion costs at the Manitoba interface with MISO. This hypothesis is based on the fact that at a high SMP, MISO is dispatching high-cost units to serve demand. These same units will be redispatched to manage congestion. All else equal, this should result in higher congestion costs.

Our regression analysis indicates a statistically significant estimate that congestion costs at the Manitoba border with MISO increase by $0.10/MWh for every $1/MWh change in the SMP.

Market Generation. Market generation is the level of generation dispatched within MISO to serve MISO demand. We hypothesize that the congestion cost at the Manitoba interface with MISO will be higher when market generation is higher. This hypothesis is based on the fact that at a higher dispatch, the transmission network is more fully utilized and congestion is more likely to arise.

Our regression analysis indicates a statistically significant estimate that congestion costs increase by $0.04/MWh for every 1,000 MW increase in system generation.

Ramp Requirements. Ramp requirements are the amount of capacity MISO expects to increase or decrease in a given hour to respond to anticipated increases or decrease in market demand or supply. In hours when demand is increasing or decreasing quickly (mid-morning and late

evening), MISO may be constrained in responding to congestion and be required to use expensive re-dispatch to manage flows over transmission facilities. We hypothesize that ramp requirements will cause higher congestion.

Our regression analysis indicates a statistically significant estimate that congestion costs increase by $0.21/MWh for every 1000 MW increase in ramp requirements.

Wind Share of Generation. Wind share of generation is the percentage share of dispatched generation that is from wind resources. When output of wind resources increases relative to the rest of the system, there tends to be higher congestion. This occurs because most wind resources are located in Western MISO so higher wind output raises west-to-east flows and congestion on the MISO system. The Manitoba interface is significantly affected because is it located in the western part of MISO. Therefore, we hypothesize that higher wind share will cause higher congestion costs for Manitoba Hydro.

Our regression analysis indicates a statistically significant estimate that congestion costs increase by $0.45/MWh for every one percentage point increase in the share of wind resources on the system.

Manitoba Hydro Exports to MISO. Manitoba Hydro export to MISO is the MW volume of exports from Manitoba Hydro to MISO. When Manitoba Hydro exports power, congestion costs are likely to increase because MISO must manage the additional west-to-east power flow in an area already affected by west-to east-congestion. We hypothesize that higher Manitoba Hydro exports to MISO will cause higher congestion costs for Manitoba Hydro.

Our regression analysis indicates a statistically significant estimate that congestion costs increase by $0.78/MWh for every 1000 MW increase in Manitoba Hydro exports to MISO.

Headroom West. Headroom West is the amount of capacity that is on line in the west (sum of the maximum output level for each unit) in excess of energy being produced from each resource. As discussed above, headroom is used to ensure operational requirements for MISO. When the MISO west headroom requirement increases, flexibility in managing west-to-east congestion decreases, because units have lower limits to which they can be dispatched in order to reduce west-to-east flows. This will tend to result in more expensive redispatch to address congestion.

Accordingly, we hypothesize that higher MISO west headroom will cause higher congestion costs for Manitoba Hydro.

Our regression analysis indicates a statistically significant estimate that congestion costs increase by $0.87/MWh for every 1,000 MW increase in MISO west headroom.

Natural Gas-Coal Price Spread. The ratio of natural gas prices to coal prices spread is used in the regression equation to account for a significant factor that affects redispatch costs. If natural gas prices increase relative to coal prices, the cost of displacing coal with gas to resolve congestion increases. We hypothesize that congestion costs will increase when the natural gas-coal price spread increases.

Our regression analysis indicates a statistically significant estimate that congestion costs increase by $1. 37/MWh for every $1/MMBTU increase in the spread between coal and natural gas prices.

Qualitative Variables. The variables described above are the "quantitative" variables used in the regression. These variables can take on a range of values, for example, natural gas prices can have a rather broad range. The regression measures the effect of changes in quantitative variable on the congestion costs. Qualitative variables measure a change in state. They generally reflect the presence or absence of a condition, for example, whether a particular observation is an on-peak hour or an off-peak hour. The following are our qualitative variables used in the regression.

Peak Hour Indicator. The peak hour indicator signals whether the observation is an on-peak hour or not. Peak hours are the 16 hours ending at 11PM on (non-holiday) weekdays. During these hours, load grows in the west and helps to alleviate the usual west-to-east flow that creates congestion. We hypothesize that congestion cost will decrease during on-peak hours.

Our regression analysis indicates a statistically significant estimate that congestion costs are $0.21/MWh lower during on-peak hours.

Winter Indicator. The winter indicator signals whether the hour is during December, January, or February. Like the peak hour indicator, we expect load in the west to grow relative to the rest

of MISO in these months and help alleviate the usual west-to-east flow that creates congestion. We hypothesize that congestion cost will decrease during winter months.

Our regression analysis indicates a statistically significant estimate that congestion costs are $1.86/MWh lower for hours in the winter.

Summer Indicator. The summer indicator signals whether the hour is in a summer month. For summer peak hours, we expect load in the rest of MISO grow relative to the west of MISO and aggravate the prevailing west-to-east flow that creates congestion. We hypothesize that congestion cost will increase in these hours.

Our regression analysis indicates a statistically significant estimate that congestion costs are $0.62/MWh higher in the summer peak hours.

The results of the regression equation are shown in Appendix B. The regression is an AR(1) model. For the ordinary least squares model, the Durbin-Watson statistic indicated that the data had a high degree of correlation between the hourly observations, which was not unexpected. Accordingly, we used an AR(1) model to account for this correlation. The results in Appendix B are the AR(1) results.

3. Effect of New Transmission Investment on Congestion.

The future congestion facing Manitoba Hydro in the western part of MISO should take into account two significant transmission expansion projects. The first is Manitoba Hydro's proposal to build additional capacity from the Manitoba Interface to Minnesota and Wisconsin as part of its preferred plan. The second is the investment that MISO initiated in 2011 to integrate wind capacity in western MISO. The regression equation used to forecast congestion is based on the state of the transmission network as it existed in 2011 and 2012. Hence, we adjust the congestion forecast to account for the prospect that congestion will be changing.

a. Wind Integration and MISO's Multi-Value Projects

MISO's planning process includes provisions to plan for and develop projects to facilitate the integration of resources to meet regulatory policies, for example, projects related to renewable energy requirements. MISO's process has resulted in substantial investments aimed at

integrating existing and future wind capacity in the western part of MISO. In fact, MISO has approved over $5 billion in projects since 2011. We believe many of these projects will be in service by 2015.

As a result of this new investment, we recognize that the congestion estimated in our forecast is likely to be overstated. In particular, the variable in our regression analysis associated with "Wind Share" measures the higher levels of congestion at the Manitoba Hydro interface when the share of wind in MISO increases. However, with the new investments in MISO aimed at integrating wind, we believe additional congestion from new wind resources is likely to be offset by the additional transmission capability. Therefore, in forecasting the congestion at the Manitoba Hydro interface, we assume changes in wind share above the level projected in 2015 will have no additional effects on congestion by capping the wind share in future years at the 2015 level. In other words, we assume the new MVP projects will completely offset the forecasted increases in output from new wind projects.

b. Manitoba Hydro Transmission Projects

As part of Manitoba Hydro's preferred development plan, Manitoba Hydro proposes to build new transmission into Minnesota and Wisconsin. These investments will help eliminate congestion into the Minnesota Hub caused by additional Manitoba Hydro exports. As our regression indicates, Manitoba Hydro export volumes into MISO create additional congestion costs at the rate of $0.78/MWh for each 1,000 MW of Manitoba Hydro exports. However, this is congestion as measured at the MISO SMP. Some of this is congestion is between Manitoba Hydro interface and the Minnesota Hub and some of it is congestion from the Minnesota Hub into the rest of MISO.

In order to separate the effects, we estimate the same regression model using the Minnesota Hub congestion cost as the dependent variable instead of the Manitoba Hydro interface congestion costs. This could identify the effect of congestion from MISO to the Minnesota Hub. We found this value to be $0.59/MWh for each 1,000 MW increase in Manitoba Hydro exports to MISO. The regression results are in Appendix B.

Therefore, the congestion caused by additional Manitoba Hydro exports is mostly between the Minnesota Hub and the rest of MISO. As a result, for additional exports into MISO after 2021 when the projects are proposed to be ready, we reduce the rate of additional congestion costs caused by imports to the coefficient estimated in the second regression model ($0.59/MWh for each 1000 MW of additional exports, instead of $0.78/MWh).

D. Full Price Forecasts

In this section we present the final results of our price forecasts: the System Margin Price combined with congestion costs and losses.

The following four figures show our estimated prices, including losses and congestion. The top line indicates the SMP. After removing congestion and losses, the bottom line indicates the LMP that Manitoba Hydro is forecasted to receive when exporting energy to MISO.

Figure 11: Potomac Economics Reference Case Energy Prices

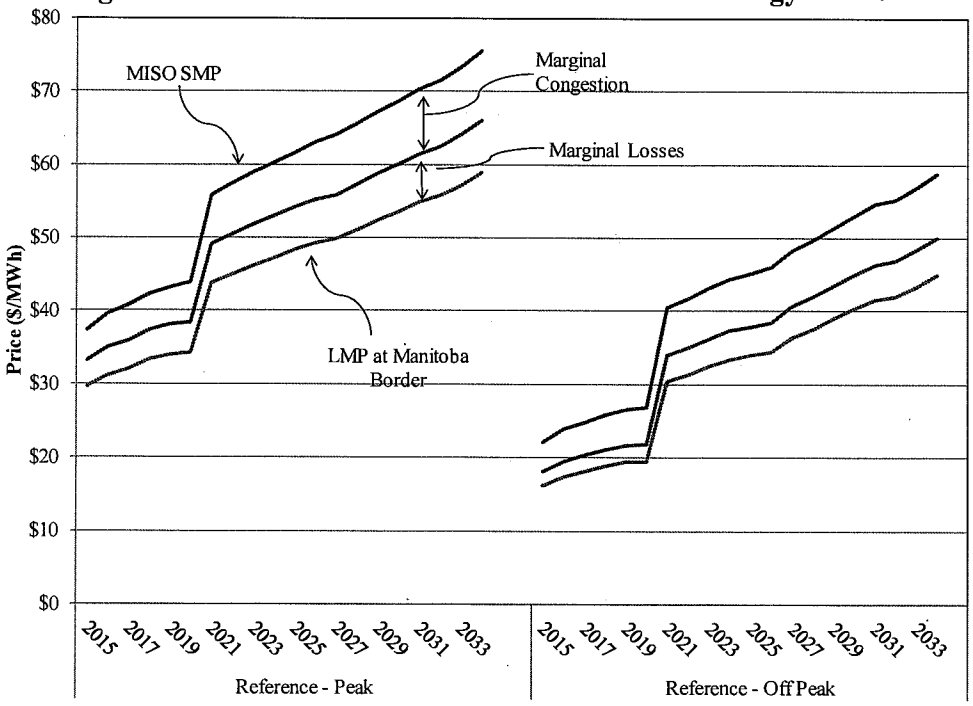


Figure 12: Potomac Economics Reference No Carbon Case Energy Prices

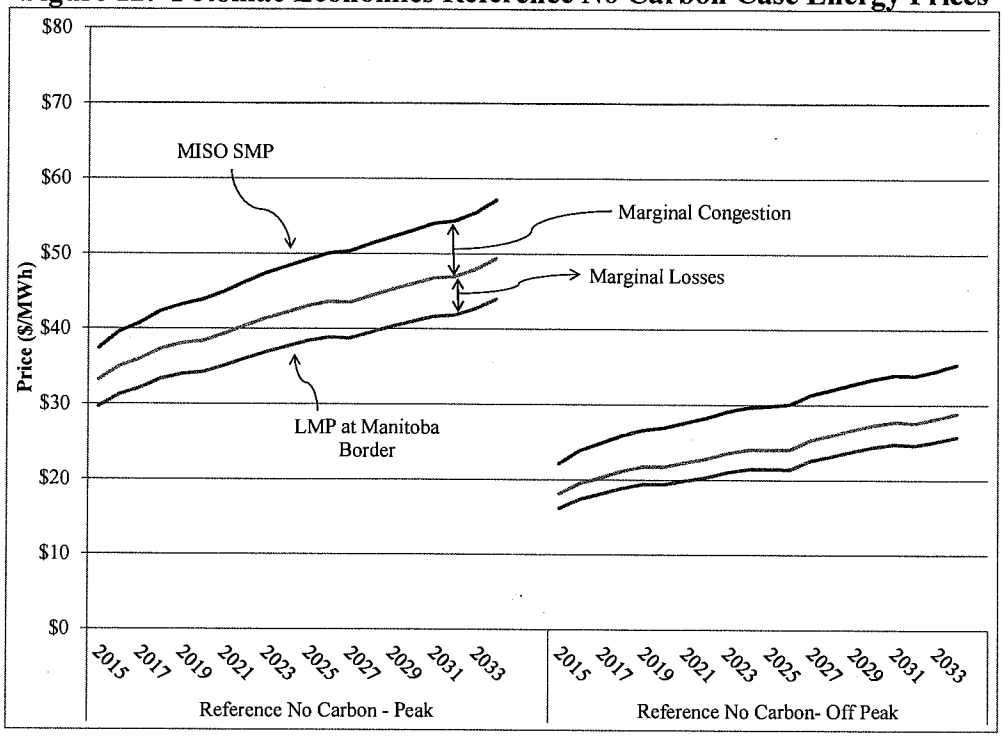

Figure 13: Potomac Economics High Resource Case Energy Prices

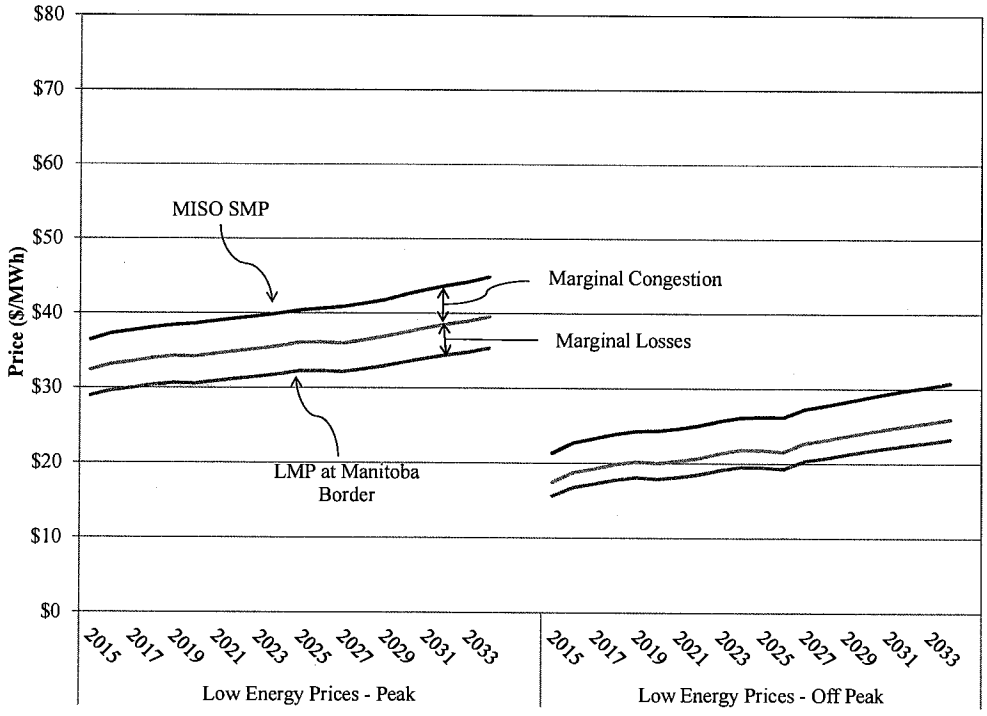

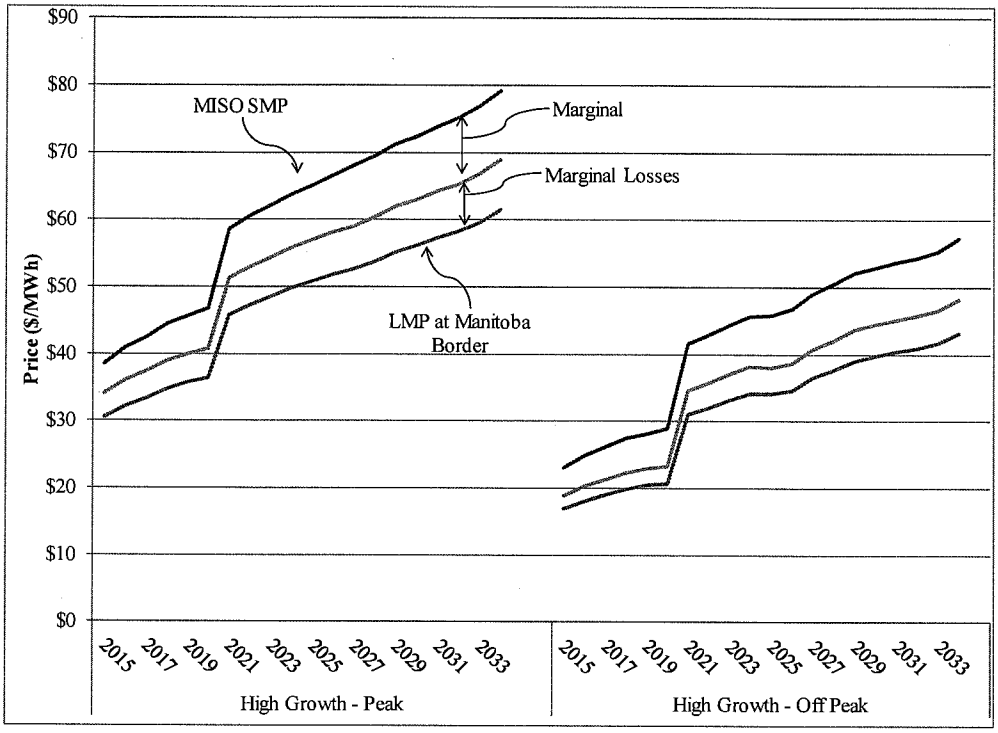

Figure 14: Potomac Economics High Growth Case Energy Prices

III. POTOMAC ECONOMICS CAPACITY PRICE FORECAST

Capacity prices in MISO's planning reserve auction have been close to zero since its introduction. This has been partly due to the prevailing capacity surplus in MISO and partly due to market design flaws that lead prices to be understated.[6] While these flaws tend to reduce the value of capacity in MISO, load serving entities will still procure capacity through bilateral contracts or build capacity when needed to meet their planning reserve requirements.

Therefore, we assume that when surplus capacity dissipates, the capacity price will rise to the level necessary to incent the construction of new resources. As a result, our capacity price forecast is based on our estimate of the net cost of new entry ("net CONE"). The net CONE of a resource is equal to the resource's annual fixed cost of new entry less the variable profit it would earn in the MISO's energy and ancillary services markets. Therefore, the estimation of the capacity price requires calculation of (1) the variable profit a new resource can earn in the MISO markets (which requires forecast of the energy and ancillary services prices); and (2) the annual fixed cost of entry for the resource.

We estimate the net CONE of an "advanced" CT, given the parameters published by EIA[7]. Given the typical price duration curve in the MISO market, a CT is generally the most economical way to meet capacity needs. While it conceivable that a CCGT, because it runs longer at lower costs, could overcome its higher capital cost relative to a CT, our analysis indicates that the forecasted energy prices always results in a CT being the most economical addition for capacity (i.e., having the lower net CONE).

A. Cost of New Entry

The cost of new entry is an annual number that reflects carrying cost of the fixed investment plus fixed operating costs (fixed O&M), as well as smaller fixed elements like taxes. We use a value that was published by MISO in support of the capacity auction prices in MISO South. Updating this value to 2013 dollars and incorporating updates in EIA's assumptions for an advanced CT,

6 See, Potomac Economics, "2012 State of the Market Report for the MISO Electricity Markets."
7 See, EIA, "Updated Capital Cost Estimates for Utility Scale Electricity Generating Plants", April 2013, *supra.*

we estimate the CONE of a CT to be $89.95. The capacity price is estimated as this value less estimated net revenues, as described in the next subsection

B. Net Revenues

Net revenues for a new advanced CT are estimated using the variable production costs of the CT and the prices forecasted for each year. If in a given hour the price is greater than the variable cost of the CT, the unit is assumed to earn the difference in the variable cost and the price. This is part of the net revenue for that hour. We also assume a CT can earn ancillary services revenue by providing off-line supplemental reserves to MISO.[8] The annual net revenues are the annual sum over all hours of the hourly net revenues and the hourly ancillary services revenues.

In the long-run equilibrium, capacity prices together with net revenues from the energy and ancillary services markets must be sufficient to cover the cost of building new resources. This is the basis for our long-run forecast of capacity prices. However, MISO currently has a surplus of capacity and has been exporting capacity to PJM. Most recently, MISO suppliers exported more than 4 GW of capacity to PJM in its auction for 2016/2017. This capacity can be repurchased from PJM in subsequent actions if it is needed to meet MISO's planning reserve needs and its costs are lower than the costs of building new resources. Therefore, we must determine when the MISO capacity market is likely to transition from its current surplus condition (which will produce lower capacity prices) to a long-run equilibrium where capacity prices should cover the cost of building new resources.

Given the current surplus of more than 6 GW and our assumed coal retirements, MISO could experience a shortfall as soon as 2016. However, the ability to repurchase MISO capacity from PJM and fund environmental upgrades that would allow some existing capacity to remain in service will push this date out. Given these factors, we project that MISO will need to begin adding new resources in 2018. Because MISO does not currently have a functional centralized capacity market, we adopt the most recent price from the PJM RPM auction of $57.39/MW-Day as our forecast for 2015 and 2016, which translates to a price of $21.65/kW-Year. In 2017,

[8] The ancillary services revenue is earned at the rate of $1/MW when the unit is not operating to provide energy. Although the average operating reserve prices are slightly higher than this level, the $1/MW assumption accounts for (1) the generator being likely to incur some costs in order to be prepared to be deployed and (2) the generator likely to be providing energy in hours when the operating reserve prices are the highest.

MISO's repurchasing of capacity from PJM should increase capacity prices throughout the region to levels similar to those that prevailed prior to the increased sales to PJM. Therefore, we forecast a capacity price comparable to the PJM clearing price in the prior RPM auction of $160/MW-Day or $49.64/kW-Year.

In 2018 and beyond, we forecast that prices will rise to the long-run equilibrium level based on the net CONE of a new CT. Table 1 shows the net revenue for each year of the forecast period, along with the annual fixed cost, and the resulting estimated capacity price. We show this for all four of our cases.

Table 1: Summary of Capacity Price Estimates

Year	Reference Case			Reference Case No Carbon			High Resource (Low Fuel Price)			High Growth		
	Net revenue	Fixed Annual Cost	Capacity Price	Net revenue	Fixed Annual Cost	Capacity Price	Net revenue	Fixed Annual Cost	Capacity Price	Net revenue	Fixed Annual Cost	Capacity Price
	$/kW	$/kW	$/kW	$/kW	$/kW	$/kW	$/kW	$/kW	$/kW	$/kW	$/kW	$/kW
2015	$20.23	$89.95	$69.72	$20.23	$89.95	$69.72	$19.76	$89.95	$70.19	$20.97	$89.95	$68.98
2016	$20.51	$89.95	$69.44	$20.51	$89.95	$69.44	$20.56	$89.95	$69.39	$21.12	$89.95	$68.83
2017	$20.92	$89.95	$69.03	$20.93	$89.95	$69.02	$20.84	$89.95	$69.11	$21.53	$89.95	$68.42
2018	$21.32	$89.95	$68.63	$21.32	$89.95	$68.63	$21.10	$89.95	$68.85	$21.84	$89.95	$68.11
2019	$21.51	$89.95	$68.44	$21.51	$89.95	$68.44	$21.26	$89.95	$68.69	$22.12	$89.95	$67.83
2020	$21.61	$89.95	$68.34	$21.61	$89.95	$68.34	$21.37	$89.95	$68.58	$22.31	$89.95	$67.64
2021	$21.59	$89.95	$68.36	$21.78	$89.95	$68.17	$21.59	$89.95	$68.36	$22.15	$89.95	$67.80
2022	$21.66	$89.95	$68.29	$22.03	$89.95	$67.92	$21.81	$89.95	$68.14	$22.35	$89.95	$67.60
2023	$21.77	$89.95	$68.18	$22.24	$89.95	$67.71	$22.00	$89.95	$67.95	$22.52	$89.95	$67.43
2024	$21.85	$89.95	$68.10	$22.38	$89.95	$67.57	$22.24	$89.95	$67.71	$22.69	$89.95	$67.26
2025	$21.99	$89.95	$67.96	$22.50	$89.95	$67.45	$22.40	$89.95	$67.55	$22.70	$89.95	$67.25
2026	$22.05	$89.95	$67.90	$22.62	$89.95	$67.33	$22.60	$89.95	$67.35	$22.84	$89.95	$67.11
2027	$22.08	$89.95	$67.87	$22.72	$89.95	$67.23	$22.59	$89.95	$67.36	$22.94	$89.95	$67.01
2028	$22.19	$89.95	$67.76	$22.90	$89.95	$67.05	$22.63	$89.95	$67.32	$23.03	$89.95	$66.92
2029	$22.31	$89.95	$67.64	$23.04	$89.95	$66.91	$22.76	$89.95	$67.19	$23.24	$89.95	$66.71
2030	$22.42	$89.95	$67.53	$23.20	$89.95	$66.75	$22.46	$89.95	$67.49	$23.20	$89.95	$66.75
2031	$22.49	$89.95	$67.46	$23.34	$89.95	$66.61	$22.29	$89.95	$67.66	$23.29	$89.95	$66.66
2032	$22.47	$89.95	$67.48	$23.37	$89.95	$66.58	$22.25	$89.95	$67.70	$23.26	$89.95	$66.69
2033	$22.59	$89.95	$67.36	$23.56	$89.95	$66.39	$22.24	$89.95	$67.71	$23.35	$89.95	$66.60
2034	$22.79	$89.95	$67.16	$23.88	$89.95	$66.07	$22.19	$89.95	$67.76	$23.60	$89.95	$66.35

Note: The "Capacity Price" column for 2015-2017 shows the estimated net revenue based on a long-run equilibrium. As discussed in the text, this price is not likely to be attained in the short run. The capacity prices for those three years (and all cases) are 2015: $21.65/kW; 2016: $21.65/kW; and 2017: $49.64/kW.

As this table shows, the net revenues from the energy and ancillary services markets do not vary substantially over time or between the various energy price cases. This is expected because the primary changes over time and between cases are related to changes in fuel prices and CO2 prices. Changes in both natural gas prices and CO2 prices will directly increase the CT's

marginal costs and, therefore, its assumed offer prices. In most hours that a CT is running, a natural gas-fired unit with similar CO2 emission rates will be the marginal unit setting the price in the energy market. This causes energy prices to increase or decrease at substantially the same rate as the change in the CT's production costs, which in turn causes its net revenue to be relatively unresponsive to these changes.

Likewise, changes in the generator mix over time. as coal plants retire and are replaced by other units, generally changes energy prices at lower load and price levels when the CT would not be forecasted to be running. Therefore, these changes do not tend to affect the CT's net revenues substantially.

Lastly, we assume no real increase over time in the capital cost of building a CT (i.e., capital costs rise at the same rate of inflation). Therefore, the CONE of the CT is flat over time and, when combined with net revenues that are relatively flat as well, we forecast a long-run capacity price trend that is comparably flat.

C. Potomac Economics' Capacity Price Forecast v. Manitoba Hydro's Consultants

Figure 15 shows our reference capacity price forecast compared to the forecasts of Manitoba's consultants. The Potomac Economics forecast rises, as discussed in the prior section, from 2015 to 2017 before achieving a long-run equilibrium that prevails from 2018 to 2034.

Figure 15: Capacity Prices Reference Case Manitoba Hydro v. Potomac Economics

REDACTED

The figure shows that the consultants' forecasts are [redacted] the Potomac Economics forecast after 2020 when most of Manitoba Hydro's new capacity enters the MISO market. As we discussed in Section I, most of the consultants assume capital costs for new resources that [redacted] than the EIA forecast that we assume. Additionally, some of the consultants appear [redacted] that a new resource would earn in MISO's energy and ancillary services markets, without which the forecasted capacity price [redacted]

We were unable to obtain detailed information on the models and inputs used by Manitoba Hydro's consultants to forecast capacity prices. Given that they are [redacted] than the fundamental approach that we used, we do not find them to be credible and recommend that PUB evaluate the business case for the Manitoba Hydro development plans on the basis of Potomac Economics' forecast.

D. Uncertainties

Although the theory underlying our capacity price forecast is sound, there is significant risk associated with these Manitoba Hydro revenues. The capacity prices forecasted for the long run may not be readily attainable by Manitoba Hydro. This is true for at least three main reasons.

First, the capacity price is based on the amount of revenue a new entrant would need to be profitable. This assumes load serving entities are seeking capacity under relatively open and competitive market structures. However, the MISO capacity market is not currently structured to establish efficient capacity prices where capacity is cleared on a multi-lateral basis. Instead, capacity prices under the MISO planning reserve auction tend to be understated. They are likely to be close to zero during periods when even a small surplus of capacity exists. This can put downward pressure on bilateral capacity prices and result in lower revenues for Manitoba Hydro.

Because of this, Manitoba Hydro will likely participate in the bilateral market, as it has in the recent past. The risk that Manitoba Hydro faces in the bilateral market is that regulated utilities may have an incentive to engage in self-build projects when they need capacity rather than purchasing from Manitoba Hydro. We have not quantified this effect in the capacity price, but only cite it as a potential risk.

Second, given the relatively long timeframe of these forecasts, it is plausible that technological advances could reduce the cost or increase the efficiency of the marginal CT, or cause alternative technology to displace the CT. In both cases, the long-run capacity price could fall and reduce the forecast capacity revenues.

A third reason why the capacity price may overstate the revenue Manitoba Hydro may earn is that the capacity price is based on net revenues earned at the MISO system marginal price. If constrained areas emerge where energy prices are much higher than the SMP, the net CONE of units built in these areas will fall. This would potentially reduce the MISO capacity price because units in these areas may be the marginal economic entrant.

IV. OTHER EXPORT MARKET ISSUES

In this section we address other issues that could significantly impact the price forecasts and revenues expectations under Manitoba Hydro's development plans.

1. Regional Issues

MISO South. In December 2013, Entergy transitioned its operation to MISO and began participation in the MISO markets. The Entergy system along with several other nearby smaller systems are part of what is known as "MISO South". The rest of MISO is referred to as "MISO Midwest." MISO Midwest and MISO South are connected by way of a transmission path that is managed on a regional basis through the Operations Reliability Coordination Agreement ("ORCA"). ORCA is an agreement among MISO and other non-MISO regional utilities to coordinate certain operations that may be impacted by the joint dispatch of MISO Midwest and MISO South. Currently, among other things, the agreement limits transfers between MISO Classic and MISO South to 2000 MW in any given hour. In the future, this limit may increase.

While the integration of MISO Midwest and MISO South promises to better allocate resources between the two areas, we do not believe it will have a significant effect on the supply and demand conditions in the western part of MISO where Manitoba Hydro anticipates making sales.

Capacity Exports to PJM. Another regional issue is the current level of MISO capacity exports to PJM. MISO is currently in a capacity surplus and exports to PJM through the PJM capacity auctions. These exports are committed for up to three years in advance As we discussed above, as the MISO capacity surplus declines, capacity exports to PJM from MISO will likely decline and this capacity will be available to meet MISO requirements.

2. Export Volumes

Manitoba Hydro assumes all additional surplus electricity can be sold either as long-term "dependable" (firm) energy or as on- and off-peak opportunity sales. Projected export volumes of long-term dependable energy are based on the surplus dependable capacity that Manitoba Hydro calculates based on historical water conditions and forecast load and resources. Manitoba assumes 100 percent of available dependable energy can be sold as long-term firm.

Manitoba Hydro on-peak and off-peak energy volumes are estimated based on simulations of the Manitoba Hydro system using its "SPLASH" model. The SPLASH model uses anticipated hydro conditions, load, resources, and export prices. The model optimizes the use of the available water to determine the volumes of exports and imports. The reasonableness of the export volumes produced by the SPLASH model was evaluated by Independent Expert Consultant, La Capra Associates.

Our role was to examine whether Manitoba Hydro can actually sell the volumes into MISO. Overall, given the small volume of additional capacity and energy resulting from the development plans relative to the size of the MISO market, we conclude that Manitoba will likely be able to sell the volumes it assumes in its plans. Our price forecasts take into account the additional volumes in estimating the market clearing prices. We also take into account the additional volumes when estimating the congestion component of the location marginal price at the Manitoba Hydro border with MISO.

Aside from the risk associated with selling capacity in the MISO market described above, we have a minor concern that the assumed volumes of long-term dependable energy may be slightly high. Manitoba Hydro assumes all dependable capacity is sold under long-term firm contracts. We do not believe all dependable capacity should be assumed to be sold forward on a long-term basis. Instead, an historical ratio could be applied. Manitoba Hydro has provided an analysis that indicates the value is close approximately 91 percent in recent years. We recommend that nine percent of the Manitoba Hydro projected long term dependable energy be "re-priced" at peak opportunity sales levels. We understand that La Capra will be addressing the effect of this issue.

We also examined Manitoba Hydro's assumption that its [redacted] We found there is some justification for this [redacted]. However, this [redacted] is not always attained. [redacted]

[redacted] We recommend the Company provide additional analysis supporting [redacted] preferably one that estimates [redacted]

3. Longer-Term Price Forecasts

Manitoba Hydro's Consultants provide forecasts to 2034. However, Manitoba Hydro projects revenues until 2080. To calculate the forward revenues, Manitoba Hydro assumes a growth rate for the years 2035-2049 based on the compound average growth rate ("CAGR") for the years 2030-2034, but declining to a growth rate of zero by 2049. Basically, growth rates in prices are linearly interpolated between the value equal to the average CAGR for the years 2030-2034 and zero value for 2049. After 2049, growth rates in prices are assumed to be zero.

With regard to capacity prices, we find no basis for assuming the real price will increase after 2034. For reasons stated above, such prices may even decline. For energy prices, we find it difficult to recommend an approach that would be reliable given the long-term nature of this assumption. We recommend that alternative post 2034 growth rates be examined in order to understand the sensitivity of the results to alternative growth assumptions. At least one such sensitivity should be a zero real growth rate, which would effectively assume that fuel prices and CO2 prices escalate at the rate of inflation after 2034.

4. Probability of Potomac Economics Cases

In this subsection, we provide a discussion of the probability of realizing the various cases we developed. We believe our reference cases are the most likely to represent the future path of prices. We believe our Reference Case and our Reference No Carbon Case are equally likely but will ultimately depend on the direction of future policy in the U.S. Therefore, we assign a probability of 30 percent to each of these two reference cases

[9] Manitoba Hydro informed us that relatively high water levels in 2011 allowed them to sell large quantities during on-peak hours in the shoulder load months, bringing down the overall on-peak per-MW sales revenue for that year.

Our high growth case assumptions do not depart significantly from our reference case. Mainly load grows faster and natural gas prices are higher.

We believe our last case reflects on-going progress in developing shale gas, which has proved to substantially increase natural gas supply in the U.S. The high resource case also shows slower load growth, primarily because gas substitutes for electricity for heating and may also become a transportation fuel, lessening load growth in the transportation sector. The slower load growth can also be a proxy for overall slower macroeconomic activity, which is reflected in this case.

We believe the High Growth and the High Resource cases are also equally likely, but less likely than the reference cases. Therefore, we assign a probability of 20 percent each to these two cases.

5.0 IT IS THEREFORE ORDERED THAT: 47

Executive Summary

By Order 116/08, the Public Utilities Board (Board) provided an April 1, 2009 conditional general rate increase of 4% (excepting for Area and Roadway Lighting customers) for Manitoba Hydro (MH, the Corporation or the Utility), subject to the Board's further review.

After a thorough and intense consideration of the evidence, and considerable contemplation, the Board will approve rate increases as of April 1, 2009 but will vary the level of the increases to 2.9%, to apply to all classes excepting for the Area and Roadway Lighting class.

By so doing, the Board balances MH's evidence of recent improvements in the Utility's financial situation and the pressures on its customers due to the recession with the Board's ongoing concern respecting the many risks faced by MH. Notwithstanding several years of contemplating and evaluating the risks, assisted by reports filed by MH and the views of Interveners, MH's risks still have not been sufficiently detailed and quantified for the Board.

Accordingly, the Board expects MH's construction program and export plans, and risks, and the implications for consumer rates to be fully defined and reviewed by the Board prior to MH's finalization of pending export agreements, and ahead of any further rate increase consideration by the Board. The Board notes that MH's current plans would have the Utility's undepreciated plant in-service increase from $12 billion (2009) to over $37 billion by the end of 2028, with a concurrent increase in long-term debt from almost $7.2 billion in 2009 to over $19.4 billion. These are "large numbers" and affect the Utility's risk profile, providing further support for the Board's expectation of a thorough review prior to finalizing pending export commitments.

That said, the Board shares MH's concern that, over time, the loss of an April 1, 2009 rate increase would compound into a material reduction of retained earnings, and, potentially, be damaging to the Corporation's future financial position and customer rate

stability. Even with the April 1 rate increase, MH's rates will remain amongst the lowest in North America, for residential, institutional, commercial and industrial customers.

In approving rate increases for April 1, 2009, and based on the evidence to date, the Board agrees with MH's assertion that the Utility's projected rate increases over the next several years, including the increase now approved for April 1, are not based on "pre-funding" major capital construction projects so as to provide a benefit to future rather than current ratepayers, but rather to ensure MH's equity levels are adequate to protect consumers and the Utility should one or more of the Utility's major risks actually occur.

While MH's latest long-term financial forecast reports a relatively attractive future outlook, the Board remains concerned that on an overall basis MH's 20-year forecasts may seriously overstate likely export revenues, particularly with respect to:

- Annual energy sales -- by assuming total energy sales at 115% of long-term average annual hydraulic generation in every year.
- A built-in supply shortfall of 10-13% of export sales, presumably to be met through financial settlement of non-delivered exports.
- The downside potential of periodic droughts.
- Possible U.S./MISO market constraints.
- The timing and magnitude of Green House Gas (GHG) control measures.
- Current and pending export contract prices and other contract conditions, which are unknown to the Board to this date.

Because the Utility's latest 20-Year integrated financial forecasts (IFF) are integral to its plans for advancing new Generation and Transmission projects, and are to be funded largely by debt, the Board continues to express substantial concerns about the potential for higher than projected domestic rate increases in the event that export revenues are lower than now forecast. Toward this end, MH will be directed to prepare a series of 20-year alternative scenarios (IFF/Power Resource Plan/Capital Plan) that reflect a number of variations to the currently published scenarios.

Accordingly, the Board will direct MH to file by September 30, 2009, for Board approval, a conceptual outline for an in-depth and independent study of all the operational and business risks facing the corporation. As well, the Board directs MH to file a 20-year capital expenditure forecast, together with draft terms of reference and timeline for a regulatory review of MH's planned capital program and its impact on consumer rates; this on or before December 1, 2009.

As to low-income consumers, and while the Board is encouraged by the commitments undertaken by MH with respect to developing a broader low-income bill assistance program, and understands that the Utility undertakes significant efforts to work-out reasonable payment plans for customers experiencing economic distress, it will expect the Utility to provide a further report well ahead of the next heating season. The report is to address options considered, provide details on the options and of the assessment made, and recommend a specific course of action that can be implemented by October 31, 2009.

Finally, the Board expects to receive all outstanding responses to past Board Directives (including those in Order 150/08), in such time so as to permit the Board to conduct a complete review of MH at the General Rate Application MH is to file by October 1, 2009, for the 2010 and 2011 fiscal test years.

1.0 Background

MH filed a 2008/09 General Rate Application (GRA) with the Board in 2008 seeking increases in electricity rates.

Following a public hearing process, which included the orderly exchange of written evidence by MH and Interveners, the Board held an oral public hearing and, subsequently, issued Order 90/08 containing preliminary findings and directives.

Included in Order 90/08 was Board approval of a 5% increase for all consumer classes (except for Area and Roadway Lighting customers) effective July 1, 2008. As well, the Board then-indicated that a further 4% increase may be granted as of April 1, 2009, with the April 1, 2009 rate increases expressly subject to reconsideration following receipt and review of additional information that the Board was requesting.

Subsequently, on July 29, 2008 the Board issued Order 116/08, which contained additional and detailed rationale for the rate changes and further direction on a number of other significant matters.

By Order 116/08, the Board again indicated that the April 1, 2009 conditional, across all rate classes, general rate increase of 4% (excepting for Area and Roadway Lighting customers) was expressly subject to the Board's further review, that, depending on developments, could result in the Board increasing or decreasing the 4% increase that had been conditionally approved. As well, Order 116/08 contained a series of directives for MH to address in fiscal 2009.

Following the issuance of the orders, MH sought to "Review and Vary" certain of the directives, which resulted in a restatement of the Board's directives, as now found in Order 150/08. (A more detailed understanding of the Board's reasons and directives may be gained through a review of Orders 90/08, 116/08 and 150/08, all to be found on the Board's website www.pub.gov.mb.ca.)

On February 2, 2009, MH filed a "Status Report" responding to the directives in Order 116/08, as amended by Order 150/08. MH also indicated in its filing that the materials it

was filing in response to the Board's directives were also being filed in support of MH's request for Board approval of the 4% April 1, 2009 conditional rate increase.

To assist the Board in its review of the material filed by MH, the Board instituted a process whereby Interveners from the 2008/09 GRA Hearing could provide submissions on both the material filed by MH and respecting the 4% conditional rate increase.

2.0 Interveners' Submissions

2.1 City of Winnipeg

The City of Winnipeg is MH's major customer in the Area and Roadway Lighting customer class.

In Orders 90/08 and 116/08, the Board indicated that there would be no rate increases for the Area and Roadway Lighting class in 2008 or 2009, a decision based on the Board's determinations following MH's GRA.

The City of Winnipeg's submission emphasized that the basis for not increasing the rates charged to Area and Roadway Lighting Customers, that being that the current rate for the class was in excess of what was required, continues to exist following the GRA, and that the additional information contained in MH's Status Report continues to support the City's position that there should be no increase in April 2009 to Area and Roadway Lighting rates.

The City of Winnipeg concluded that the Board's rulings have been based on the revenue to cost coverage (RCC) ratios for the Area and Roadway Lighting class, where, historically, the RCC for the Area and Roadway Lighting class has consistently been above the upper limit of the "zone of reasonableness" (i.e. a revenue to cost ratio falling between 95% and 105%), as well as being higher than the revenue to cost coverage ratios of other customer classes.

The City of Winnipeg submitted that as the circumstances that resulted in the Board's GRA decisions continue to exist, there is no reason for the Board to vary its decision and grant MH April 1, 2009 rate increases for Area and Roadway Lighting customers.

In further support of its position, the City of Winnipeg, after having reviewed MH's Status Reports, suggested that MH's economic conditions had generally improved since the 2008/09 GRA.

The City also brought to the Board's attention MH's 20-year electricity financial forecast, which, with three minor exceptions, projects net income higher for each year of the 10-

year period from 2009 to 2018 than was projected in MH's previous longer-term forecast, the Integrated Financial Forecast (IFF) 07-1, which was reviewed at the GRA.

The City further noted that, unlike the projections of IFF 07-1, MH's key debt to equity ratio is now projected, by the Utility, to meet the targeted goal of no more than 75% of debt from 2009 through to 2013, this according to MH's most recent 20-year financial forecast.

The City held that given MH's reports and forecasts of financial improvement, as set out in the Utility's Status Report, and the prolonged history of the revenue cost coverage ratio for the Area and Roadway Lighting customers being above the upper limit of the accepted zone of reasonableness, no increase should occur to rates charged to customers in the Area and Roadway Lighting class.

2.2 Consumers' Association of Canada (Manitoba) Inc., Manitoba Society of Seniors and Winnipeg Harvest (Coalition)

From the Coalition's perspective, a 4% rate increase is not justifiable, given the intervener's perception of a material improvement in MH's financial position, the Utility's perceived failure to control day-to-day expenditures, and the sharp deterioration in the global, Canadian and Manitoba economies. The Coalition recommended that the conditional rate increase either be rejected in its entirety, or that the rate increase be set significantly lower than 4%.

Furthermore, the Coalition renewed its call for an urgent inquiry into the projected impact of future export-related capital expenditures on consumer rates. The Coalition noted that the economic climate has changed profoundly since the conclusion of the 2008/09 MH GRA hearing, and that a global credit market crisis has intersected with a dramatic chill in global demand and output to result in forecasts of negative economic growth in 2009 (economic growth in the Province of Manitoba has been projected to be less than 1%, as compared with the 2.7% assumed in the April 2008 provincial budget).

While economic conditions for individuals and businesses have deteriorated, the Coalition noted that the financial circumstances of MH have, based on the Corporation's

published results and recent forecasts, shown marked improvement since the GRA. By way of example, Coalition noted that while MH was suggesting at the GRA that it wouldn't reach its debt to equity target until after 2018, its new projection has the Utility reaching the target in 2009.

Coalition also suggested that what it perceived as dramatic improvements in the revenue, net income and retained earnings perspective of the Utility have not been matched by progress in other areas, such as OM&A expenditures. Coalition noted that the OM&A costs for 2008/09 increased by 8%, and that the Corporation does not expect a decline in OM&A costs in 2009/10, notwithstanding the economic downturn.

The Coalition suggested that a compelling argument could be made that over the past four years MH has adopted an asymmetrical approach to improving its financial position, focussing on revenue improvements while neglecting expenditure control.

The Coalition opposed a rate increase that, if granted at 4%, would be "four times the expected rate of inflation", and would come at a time when consumers are hard-pressed by disproportionate increases in the cost of basic necessities. The Coalition also cited the global economic downturn, which has dissipated savings and made employment prospects uncertain.

The Coalition submitted that the Board should not approve a 4% increase, which is representative of $45 million in additional annual revenue for the Corporation, "out of the pockets of Manitoba consumers and businesses at this point in time", holding that such an increase would be counter-productive to local, national and international efforts to stimulate consumer spending and boost consumer and business confidence.

The Coalition recommended a rate increase no more than the projected rate of inflation, i.e. 1%, while preferring no increase. In the event the Board held an increase was required to better ensure the Corporation's financial targets are met, the Coalition suggested it be limited to 2%.

The Coalition held that MH's forecast revenue requirements going forward place increased pressure on consumer rates, and this pressure is due to planned future

capital development. The Coalition called for a separate regulatory process to consider the risks and rewards related to proposed and planned future generating station and transmission line developments, and that it be held no later than the winter of 2009/10.

2.3 Manitoba Industrial Power Users Group (MIPUG)

In its submission to the Board, MIPUG recommended:

(i) the Board should not approve a 4% rate increase as of April 1, 2009, and, at a minimum, the Board should reduce any rate increase to 2% or less; and

(ii) in considering any future rate increase applications, the Board should require MH to provide copies of current IFFs and/or 20-year financial forecasts that reflect (a) the impact of foregoing a rate increase and (b) adjusting sought-after and projected rate increases to no more than the general annual inflationary rate increase (i.e. 2%).

In its submission, MIPUG also indicated that, if the conditional 4% increase was granted, it would represent the third consecutive year of MH rate increases in excess of the Bank of Canada's annual inflation target of 2%, and would result in there having been rate increases in excess of the rate of general inflation in five of the last six years.

MIPUG included in its submissions references to Board Order 90/08, where the Board discussed the target of a debt to equity ratio of 75:25, and observed that the granting of a 4% rate increase would come during a time of a major economic downturn, which would exacerbate the impact of the rate increase on all consumers.

MIPUG Presenters at the December 2008 Energy Intensive Industry Rate Hearing indicated to the Board that MH's industrial customers are facing dire economic situations, with demand falling in local and world markets. MIPUG submitted that the current economic situation is unprecedented, and, noting the pace of recent electricity rate increases, suggested that the Board should very carefully consider the need for further rate increases at this time.

MIPUG's submission addressed the three primary reasons it perceived as being supportive of the Board awarding a higher rate increase than had been initially sought by the Utility in the GRA, those being;

- Support for the debt: equity ratio target of 75:25;
- MH's forecast capital expenditures, which could approximate $20 billion over the next 15 years, and
- Risks faced by the Utility, including the possibility of future below average water conditions, lower than expected export demand and prices, higher interest rates, further currency fluctuations, and the decisions required with the upcoming adoption of IFRS.

That said, MIPUG submitted that a higher than inflation rate increase, as sought by MH, would represent a "pre-funding" of capital projects anticipated to deliver benefits to future ratepayers. MIPUG noted that the future benefit element is reflected in the fact that MH's current forecast debt: equity ratio projects a quick decline in the ratio following the 2022/2023 projected in-service date of Conawapa

MIPUG questioned whether the 4% requested rate increase, taking into full consideration the current economic situation, represented a bid to unreasonably shift costs to current ratepayers for benefits expected for future ratepayers. MIPUG recommended the rate increase not exceed 2% on April1, 2009.

2.4 Resource Conservation Manitoba/Time to Respect Earth's Ecosystems (RCM/TREE)

RCM/TREE supported MH's application for a 4% rate increase, with observations pertaining to MH's revenue requirements, class allocations and rate design.

In examining MH's projected debt to equity ratio, estimated to be 74:26 in the current year, RCM/TREE recommended that the Board resist the temptation to reduce or eliminate the conditional 4% rate increase, rather the intervener recommended the Board proceed with and approve the 4% increase, this in recognition that the debt to

equity financial target is a long-run, not short-run, target. For RCM/TREE, with expected and considerable past annual variability in MH's revenues, the long term should remain the Board's focus. RCM/TREE noted that MH's forecast predict that after 2014 MH's projected debt to equity ratio will again fall below the long term target of 75:25.

RMC/TREE also reminded the Board that consumers pay bills not rates, and recommended that MH accelerate its DSM efforts to allow consumers to stabilize or lower their bills through reduced consumption. RCM/TREE also suggested that rate affordability measures for low-income consumers should be implemented as soon as possible, and prior to the next heating season.

RCM/TREE also recommended that the rate increase be structured so as to provide inclined rates for both residential and industrial customers; RCM/TREE considers the current second tier for residential customers as falling short of full marginal costs, and therefore a rate too low for presenting consumers with needed recognition of the full cost of electricity consumption.

Accordingly, RCM/TREE submitted that adjustments be made to the quantity of energy permitted in the first and lower-priced residential block, so that more residential customers will face second tier energy charges. RCM/TREE also prefers that the rates for the first and second tiers be designed on a revenue neutral basis.

3.0 MH's Response

In its response to Intervener submissions, MH held that there have been no material changes since the GRA that have either improved the long-term financial strength of the corporation or reduced its risks. Accordingly, MH submitted that fiscal prudence dictates that the conditional rate increase of 4%, effective April 1, 2009, be confirmed.

MH advised that attention should be paid to not only reaching but also maintaining the 75:25 debt:equity financial target, and that approval of the 4% rate increase effective April 1, 2009 will contribute towards that achievement. That said, MH submitted that even with a 4% rate increase as of April 1, 2009, long-term maintenance of the debt:equity target ratio may remain "elusive".

MH submitted that Coalition and MIPUG failed to recognize the role that the 4% rate increase would play in allowing MH to maintain its 75:25 debt:equity target. MH suggested that, over time, the loss of the April 1, 2009 4% rate increase would compound into a material reduction of retained earnings, and be highly damaging to its future financial position and customer rate stability.

MH advised that IFF-08 and the Utility's 20-year electricity financial forecast of January 2009 are based on expected or average conditions, and that the realization of certain significant risks, such as a prolonged drought, reduced export prices, or unforeseen infrastructure damage, could "derail" the corporation's planned build-up of equity.

MH disputed MIPUG's assertion that the Utility's projected rate increases over the next several years represent an attempt to "pre-fund" major capital construction projects (and provide a benefit to future rather than current ratepayers), and held that the need to build-up equity is not to pre-fund projects but to strengthen the Utility's ability to withstand risk.

In response to the critical submissions of the Coalition on the topic of OM&A costs, MH suggested that its OM&A cost levels are "proceeding exactly as represented" at the GRA (by MH), and reminded the Board of the Utility's evidence at the GRA that OM&A

costs were increasing due to various business factors that are in addition to the ongoing pressure of inflation, those being aging infrastructure, increasing maintenance, environmental monitoring requirements, increased staffing costs and domestic load growth.

MH submitted that the increases in OM&A costs should be understood in light of the GRA evidence, where the difficulty of attracting qualified professionals and trade personnel was outlined, and that there were, at that time, approximately 200 unfilled staff positions (the latter a major factor in OM&A costs being $16 million less in 2007/08 than forecast, costs that MH expected would ultimately be annually expended once staffing levels meet Utility needs).

MH acknowledged the uncertainty of present economic times, but held that there is no consensus regarding expectations as to the quantum and duration of currently lower inflationary pressures. While MH conceded that the downturn provides important context to the Board's evaluation of the April 1, 2009 conditional rate increase, the Utility also submitted there are other factors that the Board should consider, including MH's continuing position of having the lowest overall rates in Canada.

In response to RCM/TREE's submission, and while acknowledging that intervener's general support for the implementation of a 4% rate increase, MH submitted that RCM/TREE's inverted rate design suggestion is premature, and that the Utility is currently reviewing options for the long term direction of residential inverted rates, with a view to recognizing the benefits of efficiency-inducing price signals while acknowledging the lack of energy choice available to many electric heat customers.

MH suggested that a long-term plan to provide meaningful second tier rates requires stakeholder review, and that the process of developing such rates would best be furthered through a subsequent GRA.

In respect to the City of Winnipeg's submission, MH conceded that it is unaware of any changes in circumstances that would justify the Board varying its decision not to increase the Area Roadway and Lighting class rates at this time.

4.0 Board Findings

In reviewing MH's February 2, 2009 "Status Report" filings, the submissions of Interveners, and the response by MH to those submissions, there are several major, compelling and, sometimes contradictory factors that the Board concludes it must take into account in deciding on whether the April 1, 2009 conditional rate increase should be approved. These factors include MH's stated and forecast financial position, the state of the economy, and the number, nature and evolving risks faced by the Corporation,

After a thorough and intense consideration of the evidence, and considerable contemplation, the Board will approve rate increases as of April 1, though vary and reduce the level of the average rate increases to 2.9%, to apply to all classes excepting for the Area and Roadway Lighting class.

By so doing, the Board balances MH's short-term financial situation and risks with the Board's ongoing concern respecting the many risks still faced by MH. Those risks still have not been sufficiently detailed and quantified and, accordingly, the Board will require substantive elaboration of MH's construction program, export plans and risks.

The resulting implications for consumer rates should be fully defined and reviewed by the Board prior to MH's finalization of pending export agreements.

Operating Results and Financial Projections

The Board notes the reported improvement in MH's actual and forecast debt:equity ratio, and understands the improvement is largely attributable to two factors, rate increases approved by the Board and recent favourable river flows bringing additional export revenues.

MH's decision to file the 2008/09 GRA was based on IFF MH 06-4, a forecast which projected net income for fiscal 2007/08 to be $244 million, with a further forecast of $156 million of net income for fiscal 2008/09. MH subsequently filed an updated forecast IFF MH 07-1, and revised its net income forecast for 2007/08 to $264 million.

During the 2008/09 GRA, MH provided a further and oral update to IFF MH 07-1, projecting that net income for fiscal 2008 would be higher by at least $36 million, bringing the expected net income for the year to approximately $300 million. As it turns out, actual net income for 2007/08 was $340 million, an increase of approximately $96 million from that initially forecast in IFF MH 06-4, and $76 million higher than forecast in IFF MH 07-1.

Since the 2008/09 GRA, MH's actual and forecast financial performance has improved or is expected to improve significantly from that projected in IFF07-1, as reflected in the following schedule:

Statement of Operations & Retained Earnings ($ Millions)	**IFF07-1**	**Actual**	**IFF08-1**	
Fiscal Year	**2008**	**2008**	**2009**	**2010**
Revenue				
Domestic	1,078	1,098	1,125	1,204
Conditional Rate Increase		-	-	45
Export	582	625	619	546
Total Revenue	1,660	1,723	1,744	1,756
Expenses				
Finance	404	407	399	425
Depreciation	332	325	351	374
Operations & Administrative	351	335	349	358
Water Rentals	121	124	121	112
Capital & Other Taxes	57	57	65	71
Fuel & Power Purchased	132	134	150	199
Total Expense	1,397	1,382	1,436	1,539
Net income Actual/ Forecast	264	340	308	217

MH's projected net income in IFF MH 08-1 for the three-year period of 2007/08 to 2009/10 is now expected to be $774 million higher than that the Utility forecast in IFF

MH 03-1, $359 million higher than in IFF 06-4, and $341 million higher than that forecast in IFF 07-1.

The latter forecast was presented at the 2008/09 GRA, as reflected in the following schedule:

Electric Operations: ($millions)

For years ending March 31:	2008 (Actual)	2009 (Forecast)	2010 (Forecast)
Net Income			
Actual/IFF08-1	340	308	217
GRA Update	300	155	105
IFF07-1	264	155	105
IFF06-4	244	156	106
IFF06-2	174	127	122
IFF04-1	99	94	124
IFF03-1	17	29	45
Difference IFF08-1 Vs. IFF07-1	**76**	**153**	**112**
Difference IFF08-1 Vs. IFF06-4	**96**	**152**	**111**
Difference IFF08-1 Vs. IFF03-1	**323**	**279**	**172**

MH's reported retained earnings and debt:equity ratio were $1.8 billion and 75:25 respectively in 2007/08, and the Utility has since forecast further gains, with retained earnings to reach $2.1 billion in 2008/09 and $2.27 billion by the end of fiscal 2009/10, as reflected in the following schedule (to result in debt:equity ratios of 74:26, 75:25, respectively):

Electric Operations: ($millions)

For years ending March 31:	2008 (Actual)	2009 (Forecast)	2010 (Forecast)
Retained Earnings			
Actual/IFF08-1	1,795	2,102	2,270
GRA Update	1,771	1,927	2,032
IFF07-1	1,735	1,891	1,996
IFF06-4	1,651	1,807	1,914
IFF06-2	1,572	1,699	1,821

IFF03-1	877	906	950
Difference IFF08-1 Vs. IFF07-1	**60**	**211**	**274**
Difference IFF08-1 Vs. IFF06-4	**144**	**295**	**356**
Difference IFF08-1 Vs. IFF03-1	**918**	**1,196**	**1,320**

Third Quarter Financial Report

During the week of February 23, 2009, MH released its 3rd Quarter 2008/09 Financial Report for the nine months ending December 31, 2009. MH's electricity operations were reported as having developed domestic revenues of $796 million and $532 million of export revenues. For domestic revenue, this represents an increase of $36 million (or 5%) from the same nine-month period of the prior year.

As noted by the Coalition, the expenses attributed to electricity operations were reported to have increased $70 million, or 7%, from the same period of the previous year, with $32 million attributable to increased power purchase costs and $23 million due to increased operating and administrative expenses. MH attributed the increase in operating and administrative expenses to higher maintenance requirements for its generation, transmission and distribution systems.

Despite continuing criticism by the Coalition and concerns expressed by the Board, MH has yet to demonstrate recognition that there is a need for implementing more control

over OM&A expense increases. As in past Orders, the Board continues to seek more concise and effective benchmarking of MH's OM&A expenses against those of other Crown owned Canadian hydro-electric based utilities. Overall, MH forecast that its net income for the last quarter of the fiscal year 2009/10 will be sufficient to, with the first three quarter results already known, generate 2008/09 net income in excess of $300 million, this to compare with the $346 million of net income reported for the 2008/09 fiscal year. Though there has been no indication from the Utility that this most recent forecast is unachievable, the Board notes recent SEP and NEB data suggest that despite a significant decline in the value of the Canadian dollar vis a vis the American dollar, there has been a softening of export prices.

Accordingly, and while not a determining factor in the Board's rate decision for April 1, the Board wonders whether the softening of export opportunity sale pricing may result net income for 2009/10 not reaching the $300 million forecast of the Utility.

Unrealized Foreign Exchange Loss

MH's results are tied in part to currency levels, with MH selling and buying power to and from American utilities and relying on almost $2 billion of debt denominated in American dollars (borrowed to fund previous capital expenditures). MH advances the view that because export sales to American utilities are priced in U.S. dollars, and that a significant amount of those sales are through long-term contracts, the Utility has a "natural hedge" against the currency risk associated with U.S. dollar denominated debt.

Accordingly, currency swings in the Canadian dollar value of U.S. denominated debt are not immediately reflected in the Utility's annual net income reports, rather the vast majority of such fluctuations are captured in a "balance sheet" account denoted as Accumulated Other Comprehensive Income (AOCI), with the amount to be recognized within MH's annual net income reports over lengthy periods of time.

For the nine months ended December 31, 2008, U.S. foreign exchange rates increased from $1.03 CAD/USD at March 31, 2008 to $1.22 CAD/USD at December 31, 2008. This major and unexpected currency shift, largely the result of the credit crisis, the

collapse in commodity prices and the world-wide recession, resulted in a $366 million unrealized foreign exchange loss on debt in cash flow hedges on the translation of approximately $1.9 billion of net U.S. denominated debt.

The $366 million of unrealized foreign exchange losses resulted in a reported deficit of $92 million at December 31, 2008, this compares to a $305 million surplus reported as at March 31, 2008 in AOCI. MH has further reported that, based on a February 28, 2009 revaluation, the unrealized foreign exchange loss on debt in cash flow hedges has increased to $456 million (based on an exchange rate of $1.27 CAD/USD). If the Canadian dollar has not increased in value in relation to the American dollar by March 31, 2009, a further increase in the AOCI deficit is likely.

MH has indicated that the recognition of hedged export revenues during 2008/09 will contribute an estimated $11.4 million foreign exchange gain (initially accumulated in AOCI) to 2008/09's reported net income. Changes in USD debt and U.S./Canada foreign exchange rates from February 28, 2009 to March 31, 2009 could alter this appreciably.

The recent currency reversal bringing about the large level of unrealized losses currently in AOCI will, if the Canadian dollar does not appreciate materially, eventually be recognized in net income in subsequent reporting periods, as U.S. export revenue in a designated hedging relationship is realized.

The Board is concerned that the higher Canadian dollar debt levels (American debt represented in Canadian dollars) and concurrently higher interest charges may not be offset by export price increases in a recession-driven export market. That said, given the state of the world economy and the startling and abrupt movements in currency values recently experienced the implications for the Utility's 2010 and beyond fiscal years cannot be confidently forecast. There is some potential that these losses will have to be recognized in net income in the next few years.

In addition, there is a further complication, that being the upcoming implementation of IFRS. MH will have to review its hedge accounting to ensure that its current hedge

relationships continue to remain effective upon transition to IFRS. The status of this accounting policy, among others, is of considerable interest to the Board, due to the potential and material financial impact upon reported and/or forecast finances of the corporation.

Economy

Given the risks and uncertainty now present, absent the economic downturn and its impact on all domestic consumers, (residential, commercial, industrial and institutional), the Board would not have varied the conditional increase and would have approved 4% for April 1.

The compelling factor in the Board's decision to vary its initial direction and reduce the April 1 increase to 2.9% is the slow-down in the economy, which to this point does not appear to have impacted the Manitoba economy to the degree it has elsewhere, excepting for the notable exception of the decline of worth in investment portfolios held by individuals, companies and pension plans.

These factors lie at the root of the Board's decision to reduce the conditional rate increase effective April 1, 2009, and recognize the reality of material changes since the GRA evidence. When the Board held MH's 2008/09 GRA Hearing in mid-2008, the pending deterioration of the general economy was unknown.

Subsequently, the Board heard from MIPUG Presenters at the December 2008 hearing in respect of the proposed Energy Intensive Industrial Rate, that the economic downturn was impacting Manitoba's industrial customers. While commercial enterprises have the ability to deduct energy costs from taxable income, a benefit not available to consumers and not-for-profit institutions and agencies, there needs to be net income before there is taxable income; in the absence of taxable income, the impact on private enterprise of higher energy costs is similar to that on households, a decrease in net worth.

In short, the negative economic situation facing innumerable consumers supports the Board's variance of the April 1, 2009 planned conditional rate increase.

As well, and of particular note, the Board, though pleased with the Utility's intentions and efforts made to-date with respect to assisting low-income consumers, is not satisfied with MH's progress to-date with specific respect to developing a low-income bill assistance plan.

Risks

While there are factors that speak to reducing the proposed 4% increase there remain other factors that support a continuation of building up the financial strength of MH to meet the business risks the corporation faces. In its decision the Board has not lost sight of the importance of reaching and maintaining the long-term financial targets for MH, and the risks the Utility faces.

In Orders 143/04, 20/07, 90/08 and 116/08 the Board had raised concerns on the many risks faced by MH. In Order 90/08, the Board noted that MH's plans for capital expenditures may involve $18 billion or more of capital expenditures over the next 15 years; expenditures predicated in part on what appears to the Board, based on the evidence available to-date to the Board, to be overly optimistic export prices.

In Order 90/08, the Board noted that the planned level of capital expenditures will result in significantly increased debt levels, export commitments and, as a result, increased general business risks. The Board then-questioned whether the export revenue stream from new generation and transmission projects will be sufficient to cover the financial obligations related to these projects, taking into account known inherent risks, both those now present and those that may lie ahead.

In Orders 116/08 and 150/08, the Board reaffirmed the aforementioned concerns, and continued to seek additional information so as to better inform itself. MH has yet to fully comply with the Board's directives related both to export pricing and capital expenditures. Compliance with the directives, and a subsequent Board review of the implications for consumers' rates, is, in the Board's view, needed prior to MH finalizing pending export agreements.

The Board has sought, and continues to seek, assurances from MH that new export contracts are priced such as to allow MH's forecasts of future revenues from exports to be realized. The Board's concerns have been exacerbated by recent average export price history and the slowing North American economy.

In Order 116/08, the Board further indicated that it had not been provided with MH's specific export contract prices and terms and expressed concerns because of recent average export price history. MH's forecasts assumed an USD/CDN exchange rate of 1.16 and in-place carbon dioxide emissions legislation working together to positively affect export pricing, so as to achieve the Utility's forecast of average export prices of 10¢/kW.h by 2018.

If that level of export pricing is not realized, MH could be faced with an extended period of time where average export prices will not cover incremental costs associated with Bipole III, Keeyask G.S., and Conawapa G.S. If this did occur, while it would drive up the debt component of the debt:equity ratio, and reduce net income, it would represent a similar situation to that of the early experience with Limestone G.S. (in-service in1992), where costs exceeded revenue from Limestone for several years following its in-service date. This is also the expected outcome for several years following Wuskwatim G.S. coming into service.

The Board has noted in previous orders that with high construction costs, ongoing inflation and the reasonable risk that, interest rates (now being at historic lows) will rise, particularly for government-backed debt, it is in the public interest to test and ascertain whether sufficient prices will be secured on the export market to meet costs and continue to assist in holding down domestic rates.

The Board still holds that any material shortfall from required export pricing and supply/demand may well have the effect of reducing future annual net income significantly after 2018, which would place further pressure on domestic rates, assuming the debt::equity target remains at 75:25.

At the 2008/09, GRA MH then-testified to a condition of hyper-inflation with respect to construction and commodity costs, which were then-having the effect of increasing MH's projected costs for new generation and transmission projects. MH had also then-indicated that this escalation in costs had lowered the Corporation's estimate of the return to be expected from its new generation projects (Wuskwatim), a project likely to be followed by further major construction projects such as Pointe de Bois, Bipole III, Keeyask and Conawapa.

MH's concern as to construction costs was reflected in the increased cost estimates for Keeyask, an estimate that escalated by $900 million while Conawapa's estimate increased by $1.3 billion since CEF08-1. Whether the current economic downturn, which has led to job losses in the oil sands and elsewhere in occupations highly sought-after by MH, will be prolonged and lead to a reduction in currently forecast construction costs is highly speculative.

Also, it is reasonably suggested that interest rates will likely increase at some point during MH's expansion phase, placing increased pressure on the cost of operation. It is difficult to imagine that government debt rates currently in vogue can be sustained in a recovered economy.

In addition, the Board has repeatedly raised concerns with respect to the risk of drought, noting that MH has benefited from 12 of the last 16 years being of above-median water flows. Statistically, poorer water conditions can be expected to occur at some point in the future and, if prolonged and/or significant, could well have a devastating impact on MH's financial situation, as was the case in fiscal 2003/04.

MH has suggested that a drought of 2003/04's severity can be expected to re-occur once every 15 years, on average. The Board noted in Order 116/08 that longer droughts of potentially greater consequence have occurred at least three times in MH's history, and that history is very short in climatic and historical terms.

While MH has defined the potential impacts of various drought events, it has not provided a frequency-based in-depth analysis; such an analysis is required to

demonstrate the full range of economic consequence of the risk. In Order 116/08 the Board directed MH to provide such an analysis.

The Board is interested in reviewing not just the "likely" favourable outcome of various year's results, but scenarios ranging from best case to worst-case. Over the next fifteen or so years, MH's investment in fixed assets may rise, in historical cost terms, three-fold; the implications of drought rise as the value at risk rises.

The Board has also noted and reiterated concerns with the continued high level of capitalization of OM&A expenditures, which has allowed for higher than would otherwise be net income levels, both actual and projected. The Board anticipates, as does MH, though to a lesser extent, that MH's current capitalization approach will change with the adoption of IFRS.

The Board has noted that the adoption of IFRS will likely result in a higher level of OM&A expense. Such a development would impact negatively on MH's now-forecast future profitability, and could well lead to a reduction of MH's net income forecasts going out to 2017/18 and beyond.

In Order 90/08, the Board indicated that in granting a 5% increase effective July 1, 2008 and a conditional 4% increase for April 1, 2009, that:

> *"MH is of great importance to the provincial economy, its residents and businesses, and clearly it is not in the public interest to allow MH's financial condition and service capabilities to decline. Given the plans for massive new generation and transmission capital expenditures, the possibility of future poorer water flow conditions, the risk of lower than forecast export prices and higher interest rates, and the upcoming adoption of IFRS, as well as the other risks identified by the Board in Order 143/04, MH will require additional revenues going forward."*

The Board further advised that it remained focused on the risks that lie ahead and was determined to ensure, as reasonably as possible, that MH has the financial strength to meet the risks. To better understand the risks faced by the Corporation, the Board in Order 116/08 directed MH to undertake:

> *"a thorough and quantified Risk Analysis, including probabilities of all identified operational and business risks. This report should consider the implications of planned capital spending taking into account revenue growth, variable interest rates, drought, inflation experience and risk, and potential currency fluctuation"*

The Board also directed:

> *"MH to file by September 30, 2008, for Board approval, a conceptual outline for an in-depth and independent study of all the operational and business risks facing the corporation …."*

In Order 150/08, which dealt with MH's request to review and vary Orders 90/08 and 116/08, the Board reconsidered its direction that MH file a conceptual outline for an in-depth and independent study of all the operational and business risks facing the corporation, and was advised that MH would file an updated Corporate Risk Management Report. MH then-indicated that the Report would identify and quantify all the major operational and business risks facing the corporation. In Order 150/08 the Board advised that it would reassess whether an independent risk study is still needed, based on its review of information to be filed in January 2009.

Current Risk Assessment

Despite requests/directives from the PUB since the 2003/04 drought, MH has yet to provide a post-mortem on the energy supply and demand scenarios that led to the reported $436 million net loss. Nor has MH provided a forward-looking quantification of the potential supply and demand events that the corporation faces as it embarks on preparing for major new demand commitments.

The high-risk components of the 20-year IFF appear to be:

- Overly optimistic export price forecasts, forecasts of prices higher than what MH's contract rates for firm 5x16 power have to date, been able to achieve.
- Overselling hydraulic generation on an annual basis. Since fiscal 2000, MH has typically sold about 115% of its actual hydraulic generation, and relied on above average hydraulic generation (high river flows) and economically

priced imports to meet demand requirements. MH's natural gas thermal generation have not (at least to-date) been price competitive with imports.

- A presumption that, nine years out of ten, a combination of higher than forecast hydraulic generation and low cost imports will allow MH to avoid a net loss situation; and that nine years of positive results will more than offset one "bad" year.
- The presumption that any additional export revenue is positive, even if the price is below the average (or blended) cost of Generation &Transmission, let alone the Marginal Cost (MC) of new Generation &Transmission.
- The presumption that domestic rates are available to absorb losses related to droughts, infrastructure failure and/or under-performing export markets.

The ability to store hydroelectric energy provides MH considerable scope to shape energy supply to meet domestic and export demand. While the storage ability is an undeniable strength of the Corporation, the approach appears to be viewed as an unlimited and almost free attribute of MH's hydraulic system. This ability to store energy supports 5x16 peak export contracts, provides shaping for the variably available wind energy, and allows for an enhanced value for Wuskwatim run-of-the-river energy for export. Yet, it is not readily apparent to the Board whether the major components of the hydraulic generation system are being optimized.

While MH's storage capability is generally adequate to shift energy seasonally, this is not always the case on a year-to-year basis. On an annual basis, excess flow must typically be utilized within a six-month period, and depleting storage risks subsequent energy shortages (e.g. 2003-04 and 2006-07).

The loss that was incurred in the 2003-04 drought was unprecedented, and it became apparent to the Board that export operations could result in substantially increased costs for ratepayers under certain negative circumstances.

In 2004, MH suggested that while the actual event was not fully anticipated, the consequence, that being the large loss that was recorded, was largely unavoidable.

Going forward, MH advised that it would look to measures to reduce the consequences of future similar or greater droughts.

Dependable hydraulic generation for the year 2003/04 was 18,500 GWh, that being a level significantly below the 21,000 GWh on which MH bases its potential for firm export contracts (after fulfilling the domestic requirement). Yet, MH has not lowered the dependable resource level to 18,500 GWh; rather MH now defines the dependable resource as a multi-year historical event (not a one-year event). This effectively means that once every fifteen years (the deemed frequency of the 2003/04 drought event), MH will be faced with dependable energy shortfalls comparable to 2003/04; though perhaps in an environment of much higher import prices. MH has not adequately demonstrated that the Corporation's mean energy forecast adequately reflects this self-imposed additional risk.

The 2003/04 drought highlighted the increased risk that arose out of MH's strategic decision to increase exports beyond the level of surplus hydraulic generation (after fulfilling domestic need). Conversion of the Selkirk coal thermal generation to natural gas exacerbated the price-supply situation when natural gas prices soared. With MH honouring its export commitments (to preserve future opportunities) and meeting domestic need, the total energy supplied equalled 140% of actual hydraulic generation (up from the 115% contemplated in the preceding IFF's).

Following the 2003/04 drought, it was anticipated that MH would either reduce total export sales relative to hydraulic generation or ensure favourably priced imports were arranged to backstop a larger portion of the additional sales. The experience during the drought conditions of the fall of 2006-07 raised doubts about whether either change had occurred.

The 20-year IFF 08-1 confirms that MH continues to project total sales at about 115% (even as high as 120% at times) of hydraulic generation. Import projections have been increased, but not enough to be able to cover a supply shortfall equal to about 10% of forecast export sales.

The supply shortfall could be lower if it reflects the re-sale of non-delivered contract energy (significant in 2006/07 and 2007/08). This shortfall has been projected to reach the 1,000 GWh± level by 2016-17, and the shortfall apparently is not backed up by either specific budgeted imports or natural gas generated energy; this represents a substantive and distinct risk, potentially realizable in low flow years.

Future Export Prices/Revenues

As referenced in Order 116/08, MH has presented future export price scenarios to support the Corporation's revenue forecasts, including:

- GHG premiums in the U.S. would significantly increase coal generation costs by about 2011/12, and the assumption is in that case that Mid-Continent Area Power Pool (MAPP) and Midwest Independent System Operator (MISO) electricity prices would then track natural gas prices.
- Unrestricted access into the MAPP/MISO region for MH during peak and off-peak periods; and that MH's surplus energy would largely achieve peak market prices equivalent to natural gas generated electricity.
- MH's clean energy would be afforded environmental price premiums in the export market.

MH still forecasts that same scenario, although the forecast realization of it has been moved back by four to five years. MH's longer-term forecasts have average electricity export prices doubling by 2019, when Keeyask G.S. is assumed to be fully on-line. With off-peak prices likely to be substantially lower than peak prices at any time, peak prices will have to be significantly higher than the average price that includes off-peak.

MH's longer-term price forecasts have a common theme, that being that MH's clean electricity will displace coal generation, and that new clean coal generation will be considerably more expensive when it comes on-line. However, the time horizon for the technology implementation with respect to "clean" coal, is, in the Board's view, illusive,

and the economic downturn, accompanied by forecasts of massive levels of U.S. and Canadian government deficits, may distract legislators from environmental matters.

Cap and trade proposals may delay the closure of older and "dirty" coal generation in the MISO market. Even with the assumption that substantial CO_2 charges will be applied to the average cost of all existing coal generation, the average cost of coal generation could remain considerably lower than MH's short-term and long-term price forecasts. This again raises questions about the Utility's long-term export price forecasts.

Without greater access to the MISO base load, the Board currently anticipates that MH will continue to primarily serve summer peak period loads with its exports, and play a backup role to state and federal mandated wind generation.

The Board understands most of MH's long-term export contracts (existing and pending) focus on 5x16 peak energy, and it would appear that these contracts command prices generally below peak market prices, and, also, do not involve off-peak sales at above market prices. The Board anticipates the risk that in high flow years MH may still end up selling off-peak energy at 2-3¢/kW.h. If this assumption proves out, MH will have difficulty achieving near peak prices on a long-term average basis.

MISO market demand is also variable; up during cold winters and hot summers; down during warm winters and cool summers. Energy demand tends to rise and fall with seasonal weather variations. Consequently, while MH is unlikely to always realize the benefit of above average flows, it is likely to always experience the disadvantages of below average flows.

In summary, the Board is concerned that on an overall basis, MH's 20-year IFF may be seriously overstating likely export revenues with respect to:

- Annual energy sales -- by assuming total energy sales at 115% of long-term average annual hydraulic generation in every year.
- A built-in supply shortfall of 10-13% of export sales, presumably met through financial settlement of non-deliveries.

- Downside potential of periodic droughts.
- Possible U.S./MISO market constraints.
- The timing and magnitude of GHG control measures.
- Current and pending export contract prices and other contract conditions, which are unknown to the Board to this date.

Because the 20-Year IFF is integral to the plans for advancing new Generation and Transmission projects, the Board has substantial concerns about the potential for higher than projected domestic rate increases in the event that export revenues are lower than those now forecast. Toward this end, MH will be directed to prepare a series of alternative 20-year scenarios (IFF/Power Resource Plan/Capital Plan).

These should reflect a number of variations to the currently published scenarios, which appear to reflect a best case or highly favourable outlook, and include:

a) A pessimistic view of export prices (one assuming minimal U.S. - CO_2 pricing levels).

b) A periodic one-year drought (e.g., of the magnitude experienced in 2003-04).

c) A periodic multi-year drought (e.g., of the magnitude of the multi-year droughts of the 1940's or 1980's).

d) Zero long-term contract commitments.

e) A strong movement to domestic electric heating.

f) Existing transmission tie-line constraints.

g) Potential carbon tax on imports and a doubling of water rental rates.

Having reviewed the information filed, the Board remains of the view that the Utility has yet to adequately address the Board's concerns as to the risks faced by the Corporation. The Board believes a more detailed and independent risk analysis is required to assess the need and magnitude for, and of, future rate increases.

Accordingly, the Board will direct MH to file by September 30, 2009, for Board approval, a conceptual outline for an in-depth and independent study of all the operational and business risks facing the corporation. The study is to be a thorough and quantified Risk Analysis, including probabilities of all identified operational and business risks. This report is to consider the implications of planned capital spending, taking into account export revenue growth, variable interest rates, drought, inflation experience and risk, and potential further and continuing currency fluctuation.

To facilitate the Board's review of MH's risks, and in addition to the above Report, MH is to file all internally and externally prepared reports, since the 2003-04 drought, that have addressed any of MH's energy supply and other risks.

Financial Targets

While MH's current financial forecast has MH meeting its debt:equity ratio target in the short term, a deterioration of that ratio is expected as the construction of new Generation and Transmission projects is undertaken.

Since borrowing is required for new construction to proceed and a reasonable debt:equity ratio has been a concern of rating agencies, and presumably lenders, there remains a concern for all Stakeholders that a 75:25 debt:equity capital structure target may not be sufficient in this "new world" of heightened credit risk awareness.

IFRS (International Financial Reporting Standards)

In IFF 08-1, MH projects for the years 2011/12 and onward, accounting policy changes related to the conversion to IFRS. To-date, MH anticipates additional period expenses in the amount of $25 million, less offsets due to the concurrent and corresponding reductions in depreciation and amortization expense

MH has projected a provision in IFF 08-1 of approximately $10 million annually for the expensing of research related expenditures associated with intangible assets. MH anticipates that such expenditures will no longer be eligible for deferral in accordance with Canadian Accounting Standards effective for MH April 1, 2009. This provision is at this point an estimate that needs finalization.

Additionally, MH provides approximately $15 million annually, in IFF 08-1, for additional general and administrative costs and amortization of rate-regulated assets that may no longer be eligible for deferral upon the conversion to IFRS. These general provisions are also under review by MH, with a final assessment of the implications of IFRS on forecast results not expected to be available until approximately January 2010.

Adjustments to Retained Earnings in 2010 and 2012

In addition, MH assumes retained earnings write-offs of intangible and rate regulated assets of $50 million in 2010. These write-offs would be related to research related expenditures associated with intangible assets. In addition, MH projects $59 million of further write-offs for 2012, related to rate regulated assets. The write off of rate-regulated assets is consistent with MH's initial assessment of the implications of IFRS provided by MH at the last GRA.

The Board is of the view, particularly given the Utility's recognition of write-offs within the 20-year forecast period, that financial conservatism should dictate that MH reflect known financial impacts through an early adoption of IFRS standards. This would better reflect the financial reality faced by the Corporation. If such policies were adopted earlier, the Board questions whether MH would still forecast a 75:25 debt: equity ratio as early as 2009.

Frankly, the Board is concerned that the adoption of IFRS will have a more significant financial and operational impact on MH than now quantified by the Corporation. For example, the Board understands that IFRS transition rules allow for the reset of any actuarial gains and losses on the Employee Pension Plan (EPP) against opening retained earnings. MH indicated at the 2008/09 GRA that the EPP had an unamortized balance of approximately $30 million that would likely be written off against retained earnings with the adoption of IFRS. Given the recent downturn in the stock markets, the Board is concerned that pension investments may have been negatively impacted, and that this may result in additional actuarial experience losses that will further impact MH's retained earnings when written off.

The Board notes that MH and its consultant are currently engaged in developing a detailed review of the potential differences between the corporation's current accounting policies and IFRS requirements. The review is expected to also provide an assessment of the impact of those differences on net income, customer rates, and key business and information technology processes.

MH has indicated that it is unable to quantify the impact of IFRS conversion at this time.

With the implementation of IFRS there is a wide range of possible accounting policy changes and transitional elections that could have a significant impact on the financial results and forecasts of MH.

The Board understands that a quantification of potential impacts and choices in accounting policies may be available in January 2010, and the Board expects to be apprised of IFRS developments.

Accordingly, the Board will direct MH to file with the Board by February 28, 2010 an IFRS status update detailing expected changes and support for changes in proposed accounting policies. The report should include the accounting policy options that were considered, transitional elections to be made, and the potential financial impact of such policies and elections on net income, customer rates, and key business and information technology processes.

The Board will also require an updated 20-year IFF, reflecting a projection of the financial impact of the proposed changes.

Finance Expense

Comparing IFF 07-1 to MH's 20-year forecast filed in January 2009, it is apparent that the projected higher net income and lower interest rates of the early years of the Utility's forecast, and a projected strengthening of the Canadian dollar, are expected to reduce finance expense. Yet, higher capital spending begins to offset the projected and earlier reductions to finance expense in the later years of the ten-year time period analyzed.

It appears that adjustments to its forecasts made by MH have finance expense for the ten-year comparative period of fiscal 2008/09 through 2017/18 declining by $260 million to $4.9 billion in MH08-1, from the $5.2 billion forecast in MH07-1. However, on closer analysis the reduction is the result of projected higher levels of capitalized interest. (Capitalized interest is interest that is incurred but which is not charged against net income, but deferred for later amortization, that to take place over the expected life-time of the related asset.)

Projected finance expense and the relative percentage capitalized in IFF08-1 are as follows:

Finance Expense ($ millions)	**IFF08-1 (20-Year Forecast- January 2009)**										
For the years ended March 31:	**2009**	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**	**Total**
Gross Finance Expense	$ 479	$ 544	$ 597	$ 638	$ 654	$ 667	$ 748	$ 840	$ 977	$ 1,067	$ 7,211
(Less) Capitalized Interest	(79)	(119)	(165)	(160)	(111)	(148)	(214)	(333)	(457)	(469)	(2,255)
Total Finance Expense	$ 400	$ 425	$ 432	$ 478	$ 543	$ 519	$ 534	$ 507	$ 520	$ 598	$ 4,956
% Capitalized	16%	22%	28%	25%	17%	22%	29%	40%	47%	44%	31%

This compares with that forecast in IFF07-1, as follows:

Finance Expense ($ millions)	IFF MH07-1										
For the years ended March 31:	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	Total
Gross Finance Expense	$ 515	$ 572	$ 609	$ 640	$ 657	$ 695	$ 756	$ 803	$ 864	$ 906	$ 7,017
(Less) Capitalized Interest	(89)	(126)	(158)	(141)	(104)	(152)	(209)	(247)	(285)	(290)	-$ 1,801
Total Finance Expense	$ 426	$ 446	$ 451	$ 499	$ 553	$ 543	$ 547	$ 556	$ 579	$ 616	$ 5,216
% Capitalized	17%	22%	26%	22%	16%	22%	28%	31%	33%	32%	26%

As reflected in the above schedules, the percentage of capitalized interest over the comparative 10-year forecast period has increased to 31% in IFF08-1, up from 26% in IFF07-1. A higher proportion of capitalized interest is forecast to begin in fiscal year 2011, with the increase over past capitalization levels becoming more pronounced from fiscal 2016.

Over the eleven-year period 2008/09 to 2018/19, MH is currently forecasting to capitalize $2.7 billion of interest, representing 37% of incurred interest costs. The projections of higher levels of capitalization of interest remains a concern of the Board, as the practice results in a forecast of a lower debt to equity ratio and, as well, of higher annual net income, but only as long as the period of deferral continues (in short, the cost burden is shifted from the present to the future).

Operating, Maintenance & Administrative Expense

In Order 116/08 MH's OM&A pressures were described as follows:

> *"MH indicated that over the last few years the Corporation has experienced cost and operating program pressures relating to: increased maintenance requirements (due to ageing infrastructure); wage and benefit settlements that exceed inflation; additional overtime and increased staffing levels (to meet extra-provincial requirements); the expansion of programs (to meet higher customer numbers) and needs; and the meeting of environmental and other stakeholder expectations. These pressures were reported to be continuing and being compounded by a looming shortage of skilled labour, manifesting itself in higher training and labour costs."*

In Order 116/08 the Board stated:

> *"The Board remains concerned with the growth of OM&A expenses, particularly the level and growth of these expenditures prior to deferrals, capitalization and allocations to subsidiaries."*

And, as stated in Order 101/04:

> *"The Board will expect MH to maintain vigilance over its costs, so that the additional revenues [from PUB approved rate increases] contribute as they are intended to move towards achieving the debt to equity target more quickly than suggested in MH's 2003 Integrated Financial Forecast."*

Expectations from past recommendations by the Board and/or interveners related to MH achieving a reduction of OM&A expenses have not been met. In support of, and despite the variance of the April 1, 2009 rate increase to 2.9% rather than 4%, the Board expects MH to lower actual OM&A expense levels below those now forecast to assist in the Utility meeting its financial targets.

The Board's concerns are magnified given the forecast escalation in capital spending and increasing debt levels, and the concurrent forecast of a weakening financial structure as MH moves forward on major Generation & Transmission projects.

In IFF MH08-1 and the 20-year forecast, MH has removed OM&A expenses related to subsidiaries which, until this time, were reflected in the Utility's forecast of consolidated operations. The Board remains concerned with the level of growth in OM&A expenditures, with OM&A forecast to increase to $349 million in fiscal 2009, that an increase from $323 million (excluding subsidiaries), and an increase of over $26 million or 8% from the prior year.

Annual OM&A expense is forecast to grow from $400 million in 2009 to over $785 million in 2028, representing a compounded annual growth rate (CAGR) of 2.5% over the 20-year forecast. This rate of forecasted growth is inconsistent with recent historical experience, as OM&A has grown by a CAGR of 3.3% for the years 2004 to 2008, with

the annual cost increasing from $283.4 million annually to $323 million (excluding subsidiaries), and with the level of further growth projected for fiscal 2009.

MH's justification of recent and forecast OM&A escalation does not necessarily stand as valid for years beyond the next 10 years. Completion of Keeyask G.S., Conawapa G.S. and other new infrastructure should lead to a reduction in maintenance requirements and other related costs. In the Board's view, MH's recently reduced long-term domestic load growth forecast (plus or minus 1%%) does not support a continuation of annual and compounding 2.5% OM&A growth.

Furthermore, MH has indicated that synergies will be realized from the move to the Utility's under-construction new corporate head office. The realization of such synergies will be tested after the move has occurred, and the Utility should, if at all possible, rein in the annual rate of growth in OM&A expenses.

Low Income Bill Assistance Program

In Order 116/08, the Board reported that the low-income, high-energy burden problem is extensive in Manitoba, with a significant percentage of households being low-income. To assist low-income consumers, MH has relied on its Power Smart programs (problems exist in that many low-income families are unable to meet the co-funding or pre-funding requirements) to allow energy efficiency to hold down bills, efforts to work out reasonable payment schedules for households experiencing financial distress, and a voluntary program, *Neighbours Helping Neighbours,* administered by the Salvation Army. Under this voluntary program, MH customers donate to a fund that assists low-income families and seniors who are unable to pay their natural gas and/or electricity bills, MH matches the private donations and advertises the program to all of its customers.

The Board noted that while the voluntary program is beneficial, the needs are such that the program as it now operates is not sufficient to meet the need. A low-income bill assistance program should assist in reducing the energy burden faced by low-income households, and could lead to significant non-energy benefits such as increased

comfort, reduced health costs, lower bad debt write-offs, etc. Manitoba's climate is such that heat is a necessity in at least nine of each twelve months.

The Board further stated that energy affordability for low-income families is very much an issue that requires immediate attention in Manitoba. In Order 116/08 and subsequently revised in Order 150/08 the Board directed:

> *"MH to propose for Board approval (by a date to be requested by MH in its November 30, 2008 update and approved by the Board) a low-income bill assistance program, where such a program would occur in conjunction with and complimentary to an expanded low-income DSM program*."

In Order 116/08 the Board further stated:

> "MH should address the issues of: how such a rate affordability assistance program should be funded, how eligibility criteria should be determined and how levels of assistance should be determined. Consultation with the Coalition and RCM/TREE may be of assistance to MH."

In response, MH filed a report on Low income bill assistance on March 4, 2009. In that report, MH discussed possible bill assistance program expansion, and indicated it will investigate the viability of potential program expansion. MH has cited many variables that will need to be investigated, including;

- Determining Program eligibility;
- Determining Program costs;
- Determining and Quantifying program benefits;
- Determination of program funding;
- Program cost allocation;
- Customer feedback;
- Administration and implementation of the program; and
- Evaluation criteria.

The Board accepts MH's indication that implementation of a specific low-income bill assistance program will require the addressing of issues that are complex and far reaching. The Board also accepts that MH has committed to looking at all options for

some form of bill assistance, and that the Utility may consider enhancements to existing programs. The Board is particularly pleased that MH has further indicated that it will consult with stakeholders and that, after these consultations, will put forward a recommendation to MH's Board with options, implications and a process on how and if to move forward, with a report to be made to the Public Utilities Board as to MH's plans.

While the Board is encouraged by the commitments and steps made and currently being undertaken by MH with respect to a low-income bill assistance program the Board expects MH to provide a report well ahead of the next heating season, and will direct MH to provide such a report by July 31, 2009.

The report list options, provide details and implications related to the options, assess the merits of each, and recommend a specific and implementable course of action that can be put in place no later than October 31, 2009.

In its research, the Board urges MH to look to programs in other jurisdictions, and assess their potential applicability in Manitoba.

Particularly, given the current economic downturn it is vitally important to put in place protection for low-income customers with an effective bill assistance program. MH is embarking on a capital program that is predicated on consistent future rate increases, while too often low-income families do not benefit from annual increases in household income. The Board is cognizant of the impact on low-income consumers of rate increases, and expects MH to put forward its preferred low-income bill assistance program with an indication as to how many households it expects may be assisted in the near future.

Capital Expenditures & Long Term Debt

At the last GRA the Board expressed concern with the level of increased capital spending and the risks such spending has on rates.

In Order 116/08 the Board stated:

> *"The Board recognizes its statutory jurisdiction does not extend to the approval of Capital expenditures. Yet, it is clear MH's anticipated capital spending and associated increased debt levels is and will place upward pressure on rates. The Board has, as interveners have noted, expressed concern with MH's debt growth in previous orders. In Order 143/04, the Board noted:*
>
> *"The Board continues to be concerned with the progressive substantial growth in capital expenditures and accompanying debt. The Board accepts that many of the capital expenditures are related to reliability and safety, and therefore are may [sic] be prudent to incur. The Board also recognizes that many of the forecast capital expenditures are related to or the equivalent of generation expansion, such as supply side enhancements, Wuskwatim, Gull, Conawapa, and may be justified individually when considering each project's purposes and forecast results over the long term. However, collectively these projects negatively impact MH's debt to equity ratio and net income in the initial years, placing increased strain on the financial stability of MH and adding additional risk for existing ratepayers. The Board is concerned that MH has not developed a threshold for capital expenditures and associated debt growth that considers all projects, together with the health and financial stability of the Company."*

The Board reiterates prior concerns, and notes that with planned major capital expansion, such concerns are now graver.

MH's forecast of future capital spending has increased significantly since Order 116/08, and the Board reiterates its perspective that MH's planned capital expenditures are of an unprecedented scale in the Utility's history, with implications for borrowing, staffing, exports, First Nation relationships, risks and, possibly, rates.

In a Status Update filing, MH included an updated integrated financial forecast IFF 08-1, and capital expenditure forecast CEF08-1 ; an update to that provided to the Board at the last GRA (which incorporated IFF 07-1 and CEF 07-1). For the next ten years MH is now forecasting to spend an additional $3.4 billion over what it had previously planned to expend over the ten-years 2008/09 and 2017/18, details as follows:

Capital Spending- Electric Operations: CEF08 Vs. CEF07 ($millions)

	2009	2010	2011	2012	2013	2014	2015-18	10 Year Total
CEF08	1,073	1,201	1,086	851	818	1,159	7,953	14,141
CEF07	1,120	1,010	933	818	805	1,212	4,797	10,898
Increase (Decrease)	(47)	191	153	33	13	(52)	3,156	3,447

The Capital Expenditure Forecast (CEF08-1) for electric operations for the ten-year period to 2017/18 totals $14. 1 billion, compared to $10.8 billion for the same ten-year period included in CEF07-1 provided at last years GRA, an increase of over $3.4 billion. MH is now forecasting to spend over $10.0 billion on major Generation and Transmission projects for the next ten-year period, an increase from the $7.1 billion forecast in CEF07-1.

MH's forecast increased Capital spending in CEF08-1 is primarily due to an updated forecast of $2.9 billion for Major Generation & Transmission projects, of which $2.7 billion relates to an update in the forecasted capital cost for the Keeyask generating station and a further $200 million for a new Dorsey to U.S. border transmission.

Major revisions have been made to the budget for the Keeyask G.S., which has now been forecast at $3.7 billion in CEF08-1. In addition, MH has included a general provision for anticipated capital cost escalations of $236 million. MH has also indicated that the January 2009 updated estimates are still under review, this due to "uncertain" economic conditions.

The updated CEF08-1 projects that from 2008/09 to 2018/19, the Corporation plans to spend $16.0 billion, of which $11.6 billion is for new major generation and transmission assets and $4.4 billion for other power supply requirements.

Capital Expenditure Forecast 2009 to 2028

Though requested to do so by the Board, MH did not provide a 20-year Capital Expenditure Forecast to 2028, but did provide some indication of anticipated increases in Capital spending to that date.

Based on the status update filings, the Statement of Cash Flow in MH's 20-year IFF forecasts over $455 million in additional planned capital spending over the 11-year period 2009 to 2019, from that forecast in CEF08-1.

In addition, given the 20-year IFF forecast provided through 2028, the Board is aware that to serve potential new long-term export contracts to Wisconsin and Minnesota, MH will require additional generation and transmission from Keeyask, by 2018, and Conawapa, by 2022.

MH indicated that capital spending on major Generation and Transmission projects had increased by an additional $3 billion from that forecast in CEF08, as follows:

Major Generation & Transmission 20 Year Forecast Update January 2009 ($ millions)	**20 Year Forecast**	**CEF08-1**	**Change**
Keeyask Generating Station	4,600	3,700	900
Conawapa Generating Station	6,300	4,978	1,322
Unidentified GS improvements and upgrade projects			-
Project 1: In service 2019/20	245	-	245
Project 2: In service 2022/23	281	-	281
North - south transmission requirement [In-service 2022/23]	344	-	344
	11,770	8,679	3,091

MH provided a further update on the in-service cost estimate for Keeyask G.S. of $4.6 billion, this is an increase of over $900 million from that forecast in CEF08-1. MH also

projected capital expenditures of $6.3 billion for Conawapa G.S., an increase of $1.3 billion from CEF08-1. MH indicated the current updated estimates remain under review.

In addition MH made a general provision for capital expenditures related to two unidentified generating station improvement and upgrade projects. One project is anticipated to be in service in 2019/20 at an approximate cost of $254 million, the second unidentified project represents provision of $281 million for in service in 2024/25. MH has also identified in additional north-south transmission requirement to be in service in 2022/23.

At the recent GRA, MH indicated that there may be a need for a natural gas fired generating station, which could be required to deal with any delays in bringing Keeyask and Conawapa online. Yet, it is not clear from the most recent filings whether such a requirement and plan has been contemplated in MH's updated forecast.

In addition to the major Generation and Transmission increases, MH's projection also includes an increase of 5% per year for escalation in base capital spending, and 2% escalation per year in DSM spending, both commencing in 2019/20.

Based on the most recent information filed by MH, it appears that the Utility presently plans to expend on capital projects, from 2009 through 2028, in the area of $26 billion, of which approximately $17 billion relates to major Generation and Transmission projects and $9 billion on other capital spending. The majority of future spending on major Generation and Transmission projects is expected by 2025.

Given this occurs as currently planned, MH's undepreciated plant in-service would increase from $12 billion (2009) to $37.3 billion by the end of 2028, and, concurrently, long term debt will increase from $7.2 billion in 2009 to over $19.4 billion by the same end date, representing an increase of $12.2 billion in the next 20 years. The forecast growth in long-term debt is quite substantial, particularly when compared to the current provincial debt of approximately $11 billion, which includes MH's current long-term debt.

Borrowings of this magnitude will involve very high interest costs, with annual payments likely to increase to in excess of $1 billion annually. If the forecast interest rates on new

debt are actualized and the anticipated export demand and pricing also occurs, this level of interest may prove manageable. Though, and presently, the Board does not share MH's optimistic view on future export prices.

The Board expects MH to file a full and revised 20-year capital expenditure forecast, and, as well, the terms of reference and timeline for a regulatory review of MH's planned capital program and the implications for consumer rates.

Pre-funding of Capital Expenditures

While MH has denied MIPUG's contention that recent and proposed rate increases in excess of inflation amount to pre-funding of Generation & Transmission system expansion for export, it is true that a stronger financial structure with a higher level of retained earnings do support the viability of these ventures.

MH has acknowledged that both Keeyask G.S. and Conawapa G.S. are being built earlier than required for domestic load. As such, they are to provide the dependable energy required to meet export requirements. The dependable output of Keeyask and Conawapa, estimated at about 7,500 GWh (2,000 MW), is only about 20% greater than the contractual export commitments for energy.

In the absence of any of the three pending export contracts, neither Keeyask G.S. nor Conawapa G.S. would be required until at least 2030-31. This suggests that the two Lower Nelson River plants are being advanced by 10-15 years to service these export contracts.

MH advises that Bipole III is being built for primarily domestic system reliability purposes, though in advance of meeting new export commitments. MH holds that there should be no new transmission costs attributable to the new generation facilities. This implies that there are no HVDC transmission reliability issues for the current export loads and suggests that exports are served from southern generation and Upper Nelson River generation, with only domestic load being served by Lower Nelson stations.

If the scenario were reversed, it could be argued that in the absence of export contracts MH might well look to addressing its domestic reliability concerns by adding natural gas generation and/or import purchase agreements. In the early 1990's, MH chose not to proceed with Bipole III when a 500 MW sale to Ontario was cancelled and related plans to build Conawapa G.S. were shelved. Apparently domestic reliability was not a sufficient justification at that time.

Capital projects such as Bipole III, Keeyask G.S. and Conawapa G.S. will generate considerable economic activity in Manitoba. The benefits of this level of economic activity will be realized in part by the current residents of the province, who are also rate payers who will be required to pay higher "real" energy bills if rates rise faster than inflation. And, new skilled labour may move into Manitoba expanding the tax base and customer base.

Some of the early costs of new Generation & Transmission relate to First Nations involvement. The immediate financial gains for these communities do benefit overall tax payers in the short-term, and a better trained workforce leads to long-term gains for Manitoba industry in the longer term.

MH's approach to the capitalization of all interest charges during the project construction period, defers project costs until in-service when there is a revenue stream (from exports) to cover the annual costs. As such, current ratepayers are not assessed the rate increases that would be required to hold to the financial targets if interest costs were expensed during the planning and construction phase of new capital projects. Because Generation & Transmission plants frequently operate at a loss in the early years, but with the real probability of large excess revenues 10 to 15 years in the future, there will always be some question of the balancing of benefits between customer generations, but hopefully, and taking into account the overall impact on the economy and ratepayers, all generations will benefit in the end.

As an example, Limestone G.S. did not generate a positive cash flow during the first six to eight years of operation, but has provided large excess annual revenue after 12

years. Current ratepayers are benefiting from the rate increases in the early years and from export revenues in the last five or six years. The expectation is that this experience will repeat itself with the new generation and transmission expenditures, and affect the Corporation's financial strength, thus risking significant domestic rate increases if a major risk such as a multi-year drought were to occur.

Intergenerational cost shifting is almost inevitable. In the context of protecting a power supply resource, a level of pre-funding as an offset to cost deferral would seem to have merit and in the Board's view be in the public interest.

Note: Board decisions may be appealed in accordance with the provisions of Section 58 of *The Public Utilities Board Act*, or reviewed in accordance with section 36 of the Board's Rules of Practice and Procedure. The Rules are available at www.pub.gov.mb.ca.

5.0 IT IS THEREFORE ORDERED THAT:

1. MH's Application for approval of a 4% rate increase, effective April 1, 2009 BE AND IS HEREBY VARIED.

2. MH is to immediately file, for Board approval, revised rate schedules, to take effect April 1, 2009 and demonstrate and recover a 2.9% increase in revenues derived from energy rates (consistent with the methodology as contained in Appendix 9, Attachment 'D' to the February 2, 2009 Status Report) from all customer classes, except for Area and Roadway Lighting.

3. MH to prepare a series of alternative 20-year scenarios (IFF/Power Resource Plan/Capital Plan), to reflect:

   a) A pessimistic view of export prices (minimal U.S. - CO_2 pricing levels).

   b) A periodic one-year drought (e.g. 2003-04).

   c) A periodic multi-year drought (e.g. 1940's or 1980's).

   d) Zero long-term contract commitments.

   e) A strong movement to domestic electric heating.

   f) Existing transmission tie-line constraints.

   g) Potential carbon tax on MH's imports and a doubling of water rental rates.

4. MH to file by September 30, 2009, for Board approval, a conceptual outline for an in-depth and independent study of all the operational and business risks facing the corporation. The study to be a thorough and quantified Risk Analysis, including probabilities of all identified operational and business risks. This report should consider the implications of planned capital spending taking into account export revenue growth, variable interest rates, drought, inflation experience and risk, and potential currency fluctuation.

5. In conjunction with the outline requested in Directive 4, MH is to file all internally and externally prepared reports, since the 2003-04 drought, that address any of and all of the energy supply and other risks faced by MH.

6. MH to file with the Board by February 28, 2010 an IFRS status update report detailing the support for changes in proposed accounting policies, including accounting policy options considered, transitional elections to be made, and the potential financial impact of such policies and elections on net income, retained earnings, customer rates, and key business and information technology processes as well as providing an updated 20-year IFF reflecting the financial impact of the proposed changes.

7. MH file, on or before December 1, 2009, a full 20-year capital expenditure forecast, together with draft terms of reference and timeline for a regulatory review of MH's planned capital program and its impact on consumer rates;

8. MH file, ahead of the 2009/10 heating season, an update of its plans for a low-income bill assistance program; and

9. MH file its next General Rate Application, including any rate adjustment requests for both 2010 and 2011, by October 1, 2009.

INTEGRATED FINANCIAL FORECAST

3.0 OVERVIEW

Tab 3 provides an overview of Manitoba Hydro's Integrated Financial Forecast, and Debt Management Strategy. Section 3.1 and Section 3.2 discuss Manitoba Hydro's 2016 Integrated Financial Forecast (IFF16) and Electric Operations Forecast (MH16). Section 3.3 discusses Manitoba Hydro's Debt Management Strategy.

3.1 INTEGRATED FINANCIAL FORECAST

The Integrated Financial Forecast (IFF) is Manitoba Hydro's primary planning document for projecting the future financial direction of the Corporation. IFF16 sets forth the projected financial results and financial position of Manitoba Hydro for the 10-year period to 2026/27. Its purpose is to provide an indication of the Corporation's long-term financial direction. The IFF serves as the primary forecast to determine the need for rate increases and the detailed forecasts in years two and three of the IFF form the basis of the revenue requirement portion of the Corporation's electric rate application.

The IFF is based on various component forecasts from across the Corporation including:

- Economic Outlook,
- Energy Price Outlook,
- Electricity Export Price Forecast,
- Power Smart Plan,
- Electric Load Forecast,
- Domestic Revenue Forecast,
- Resource Plan Assumptions and Analysis,
- Generation Cost & Interchange Revenue Forecast,
- Capital Expenditure Forecast, and
- Operating & Administrative Expense Forecast.

The events of the past year are noteworthy in the Corporation's preparation of IFF16. In May of 2016, a new Manitoba Hydro-Electric Board (MHEB) was appointed. The Province of Manitoba issued a mandate to the Minister of Crown Services to work with the MHEB to review the circumstances around the Bipole III Reliability Project, which also resulted in a review of the Keeyask Generating Station Project. It has been necessary for the MHEB to examine and consider an enormous amount of information on a broad array of topics and make its independent determination of how Manitoba Hydro should move forward. Therefore the preparation of the Corporation's financial forecast occurred later in the planning cycle that has normally occurred in the past.

IFF16 was approved on April 28, 2017 and can be found in Appendix 3.1. IFF16 includes segmented forecasts for electric operations (MH16), natural gas operations (CGM16), and corporate subsidiaries (CS16). In addition, in this Tab, the 2016 Economic Outlook and additional information with respect to the determination of Manitoba Hydro's interest rate forecast are provided in Appendix 3.2.

As outlined in Section 2.3 of Tab 2, past financial forecasts have reflected a deterioration in the equity ratio to below 15% during the current phase of debt funded capital investment as well as a 15 year time frame for restoring a 25% equity capitalization. Due to the changes in conditions, outlook and Corporate governance, Manitoba Hydro believes that the risk faced by the Corporation requires the mitigating actions necessary to improve the Corporation to 25% equity capitalization within 10 years.

Manitoba Hydro has prepared IFF16 to 2026/27 to focus on the financial forecast over the next 10 year period. However, recognizing that a 20-year outlook has been provided in past proceedings, the MH16 20-Year Outlook is provided for informational purposes in Appendix 3.3.

3.2 ELECTRIC OPERATIONS FORECAST (MH16)

The MH16 forecast contains the projected financial results for electric operations to 2026/27. Manitoba Hydro's financial targets have been set for consolidated operations; however as requested in past proceedings, Manitoba Hydro has also provided financial

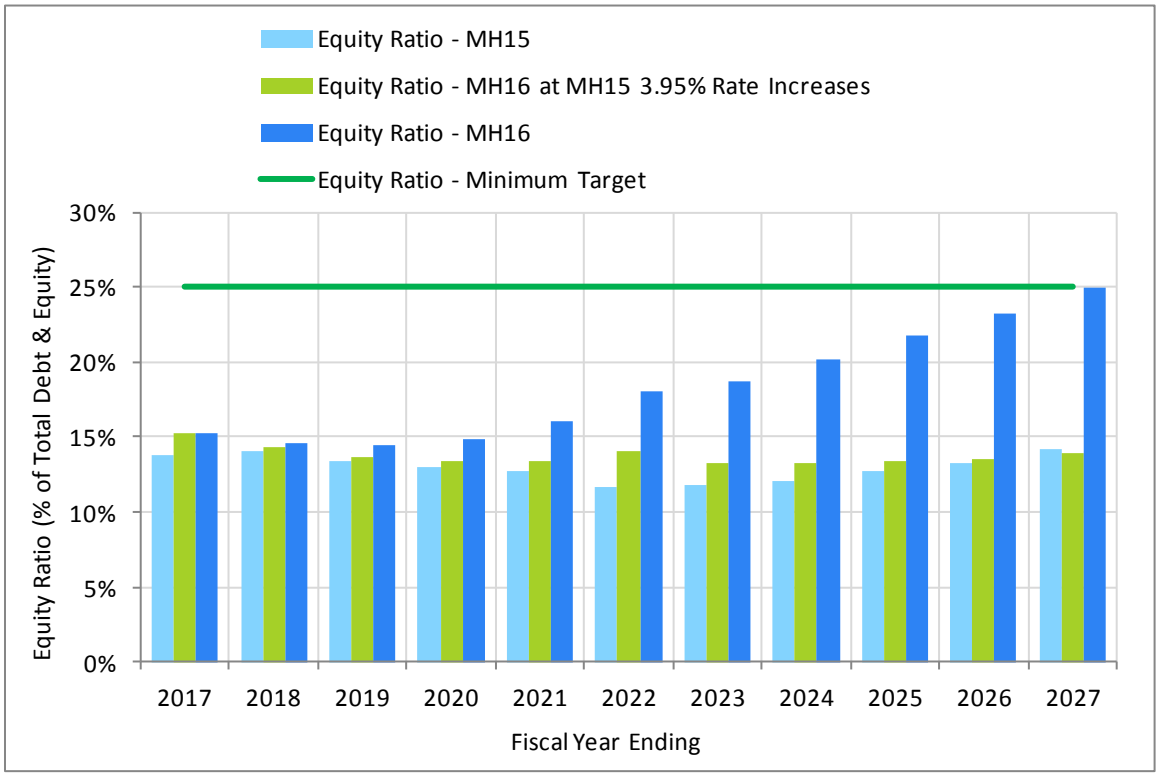
ratio calculations for electric operations in Appendix 3.3. Given the dominant size of electric operations in relation to consolidated operations, these calculations usually differ only slightly from consolidated ratio calculations.

MHEB has approved a five-year rate strategy in IFF16, projecting 7.9% annual electric rate increases from 2017/18 to 2021/22 followed by inflationary 2.0% indicative rate increases thereafter.

This rate strategy essentially compresses the previously projected 3.95% annual rate increases which were planned until 2028/29, into the next five year period in order to achieve the following objectives:

- Offset the reductions to domestic load and electricity export price forecasts;
- Mitigate the upward pressure of borrowing requirements and costs on future revenue requirements;
- Mitigate the deterioration of Manitoba Hydro's financial position thereby reducing the likelihood of being an encumbrance on the Province of Manitoba's financial position;
- Provide financial insurance that minimizes the impact to customer rates under a significant risk event; and
- Enables a return to inflationary level rate increases much earlier than contemplated under previous forecasts.

While MH16 is underpinned with a series of proposed 7.9% annual rate increases from 2017/18 to 2021/22, Manitoba Hydro is seeking approval of the 2017/18 and 2018/19 rate increase at this time, in addition to confirmation of existing rates currently approved on an interim basis. Actual rate requests made in future applications will reflect the circumstances and outlook at that time and will be subject to the review and approval of the MHEB.



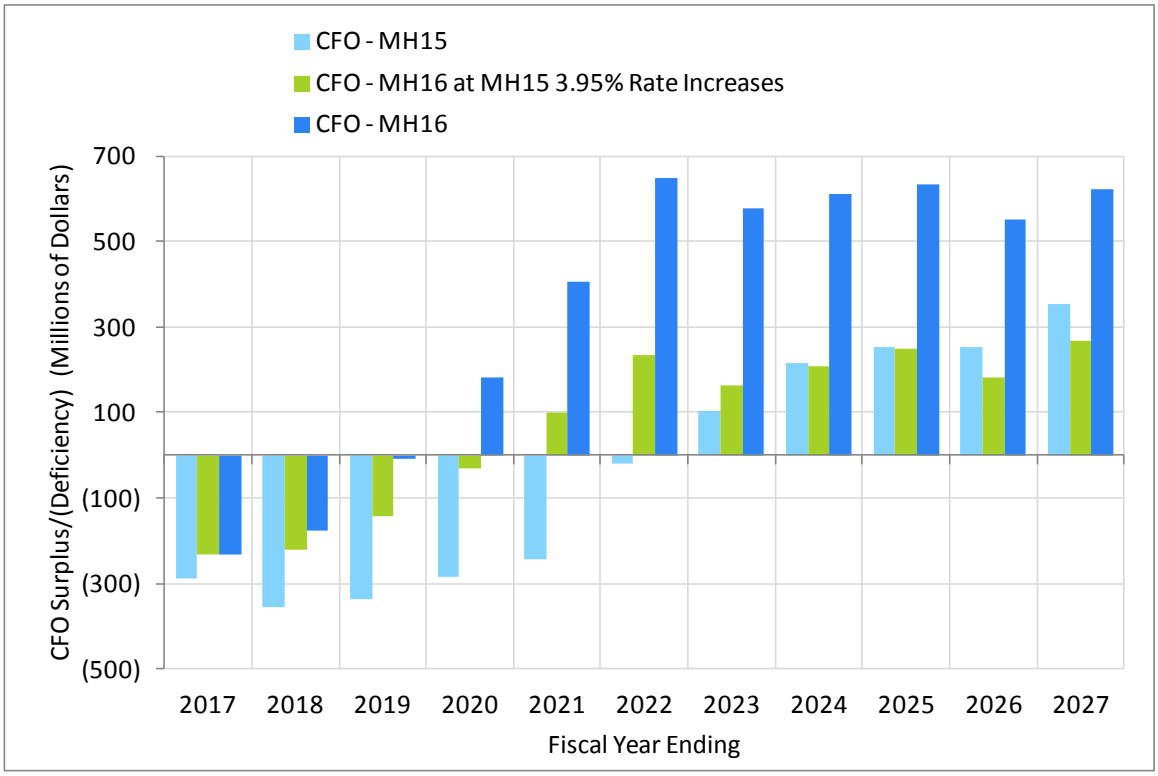
3.2.1 10-Year Electric Operations Financial Outlook

Comparison of Equity Ratios:

Figure 3.1 below compares the resulting equity ratios between MH16, MH16 at 3.95% rate increases (Appendix 3.4) and MH15. If Manitoba Hydro were to include the

previously forecast rate trajectory of 3.95% increases until 2028/29 in its current forecast, the MH16 equity ratio shown does not show signs of financial recovery within the 10 year forecast period. The return to a 25% equity target does not occur until 2035/36 which compares to 2031/32 under MH15. In Manitoba Hydro's view, a financial plan that returns the Corporation to a 25% equity level over almost 20 years is not credible as a commitment to being a self-supporting entity.

Figure 3.1 Comparison of Equity Ratios



Comparison of Cash Flows:

The following **Figure 3.2** shows the annual cash flow surplus or deficiency after business operations capital expenditures under MH16, MH16 (at 3.95% rate increases) and MH15. As explained in Section 2.2 of Tab 2, this methodology better illustrates the cash flow impacts and the need for increased revenue, which in turn minimizes the need for incremental borrowing which carries a further increase in finance expense ultimately to be recovered from customers and adds to the financial risk of the Corporation.

Figure 3.2 shows the persistent cash flow deficiency in MH15 over the first 5 years of the forecast. Savings from Manitoba Hydro's accelerated cost reduction program, lower forecast interest rates, and favourable near term water flow conditions on their own are not enough to completely reduce the cash flow deficiency shown in MH16 (at 3.95% rate increases). Even with 7.9% rate increases in MH16, the cash flow deficiency is not eliminated until the 4th year of the forecast in 2019/20. Thereafter, forecast surplus cash flows are available for debt retirement which would further improve Manitoba Hydro's equity capitalization.

Figure 3.2 – Comparison of Cash Flow Surplus or Deficiency for MH15 and MH16

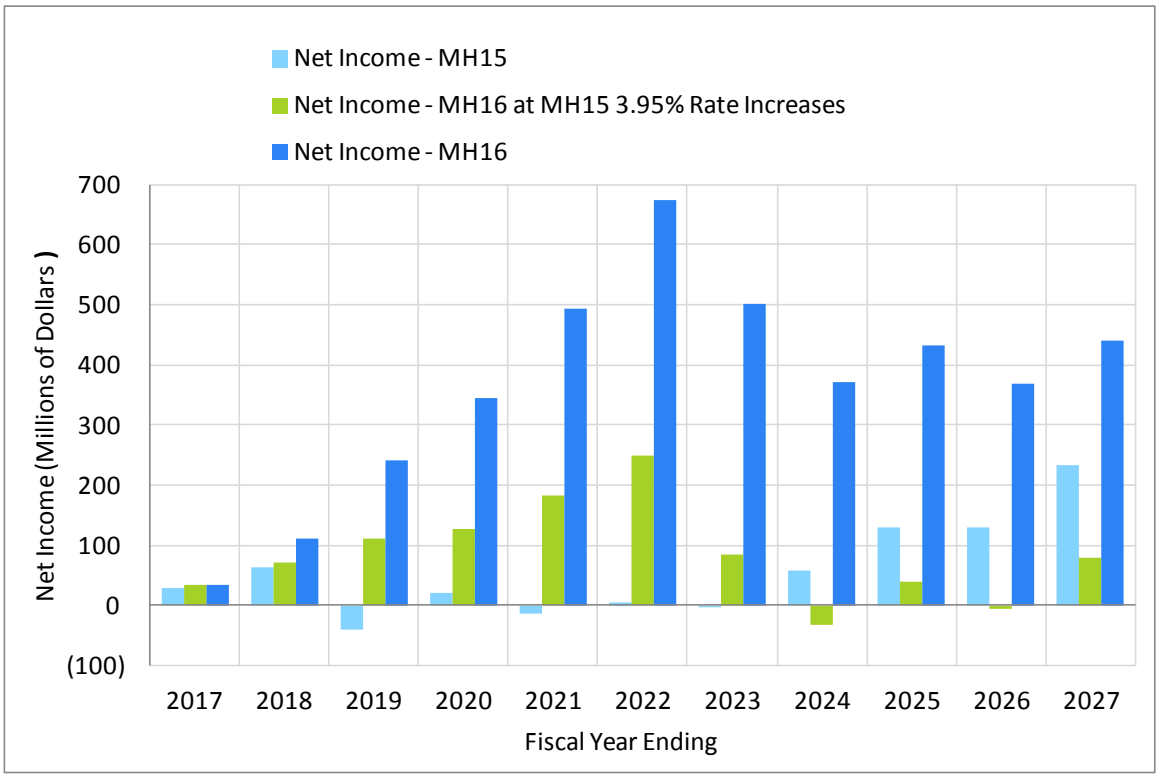
The advancement of rate increases into the first 5 years of the forecast mitigates future additional rate pressure on customers in the event the Corporation experiences adverse water flow conditions, higher interest rates, lower export prices or some other adverse risk event. Tab 4 Financial Targets and Uncertainty Analysis discusses the impact of such risks in greater detail.

Comparison of Net Income:

The following **Figure 3.3** compares MH16 net income first to MH16 (at 3.95% rate increases) and to the net income projected in MH15.

The MH15 annual net income level shown in **Figure 3.3** is approximately $55 million on average over the 10-year forecast period. Assuming the same 3.95% rate increases as MH15, MH16 shows on average approximately $85 million in net income annually. The improvement in net income in MH16 results from factors other than rate increases mainly due to the change in two non-cash income components:

- The inclusion of regulatory deferral accounts in MH16 for depreciation and overheads not eligible for capitalization established for rate setting purposes to address the PUB's findings in Order 73/15; and
- The additional interest capitalization on Keeyask over the 21 month delay period.



If not for these factors, MH16 net income (at 3.95% rate increases) over the 10 year forecast would be approximately the same as MH15 notwithstanding a significant forecast reduction in operating and administrative costs and interest rates.

MH16 is inclusive of significant workforce reduction, procurement and financing cost savings over the 10 year forecast period. These reductions, along with lower forecast interest rates compared to MH15, are necessary to mitigate the revenue impacts resulting from the reduction in the load forecast and export prices dominating this forecast.

It must be recognized that Manitoba Hydro's net plant in service increases over the 10-year period from approximately $12 billion to almost $27 billion in 2026/27. Even with cost reductions and the proposed rate increases, debt will peak at $23 billion in 2021/22. The appropriate amount of net income and positive cash flow Manitoba Hydro should generate should reflect the growing size of its balance sheet and the risks associated with the significant levels of debt required to fund this investment.

The levels of net income and cash flow proposed in MH16 are a significant change from MH15. The previous forecast projected only a modest $600 million growth in equity by 2026/27. Levels of earnings for a Corporation with $12 billion of assets in service must be scaled up significantly to reasonably address the risks associated with operating $27 billion worth of assets. Increased levels of net income will consequently result in improvements to the levels of retained earnings and steady progress towards the minimum equity target of 25% in the 10 years of the forecast.

Figure 3.3 Comparison of Electric Operations Net Income

<u>Comparison of Revenues and Expenses:</u>

Figure 3.4 below summarizes the changes in the revenue and expense components of net income between MH16 and MH15.

In comparing MH16 and MH15, MH16 rate increases are first held constant with the 3.95% rate increases projected in MH15 in order to isolate the financial impacts of other key factors changed from MH15. The financial impacts of the incremental rate increases

from 3.95% to 7.9% are then summarized at the bottom of **Figure 3.4** to show the projected net income including 7.9% annual rate increases from 2017/18 to 2021/22.

*MH15 has been restated to reflect Bipole III Reserve Account amortization in Domestic Revenues rather than Other Revenue.

Lower Finance Expense

Finance expense in MH16 is $1.7 billion lower in the 10-year period to 2026/27 in comparison to MH15 due to the extended period of deferred financing charges associated with the 21-month Keeyask delay through interest capitalization ($0.6 billion); lower forecasted interest rates ($0.5 billion); a plan to shorten the average term to maturity for new debt issuance from 20 to 12 years ($0.5 billion); as well as lower finance expense on lower debt volumes associated with projected higher rate increases and savings from Manitoba Hydro's cost reduction program and the beneficial reduction in the compounding of lower debt service costs ($0.8 billion). These reductions to finance expense are partially offset by the increase in projected borrowing and interest payments associated with the increase in major capital project costs ($0.7 billion).

The 21-month delay in the Keeyask in-service date results in an additional $0.6 billion in interest capitalized to the Keeyask project and an equivalent reduction in finance expense. Although the conventional accounting practice of capitalizing interest costs to the in-service date defers the impacts of financing costs to net income and revenue requirement, Manitoba Hydro is still required to meet the related interest payment obligations. When combined with the lost net extraprovincial revenues over the delay period and the $2.2 billion increase in capital cost, further deferral of Keeyask interest charges ultimately translates into higher borrowing and financing costs that must be paid by customers. This can be demonstrated by holding the MH15 3.95% rate increases constant in MH16 and observing the delay in achieving the target 25% equity ratio by seven years to 2033/34 (Appendix 3.4).

As part of Manitoba Hydro's cost reduction plan, Manitoba Hydro plans to shorten the average term to maturity of new debt issuances, thereby further reducing Manitoba Hydro's debt portfolio weighted average interest rate and debt servicing costs. In past forecasts, Manitoba Hydro used a planning assumption whereby all new Canadian debt issuances carried a 20-year term to maturity and corresponding forecasted 20-year average interest rates (the average of the forecasted Manitoba 10 and 30-year interest rates). For MH16, a 12-year weighted average term to maturity and forecast 12-year weighted average interest rates were used, effectively lowering the forecast yield rate on new Canadian borrowings by an average of 50 basis points annually. The financial benefit associated with this forecasting assumption change has the potential to provide

approximately a $0.5 billion savings in debt servicing costs over the 10-year forecast period to 2026/27. Manitoba Hydro's execution of this strategy is dependent on achieving the revenues (i.e. rate increases) and cost savings embedded in MH16.

Manitoba Hydro's Workforce Reduction Plan

Manitoba Hydro's commitment to deliver significant cost reductions has also significantly contributed to the improvement in projected net income. Execution of the cost reduction plan began in February 2017 when Manitoba Hydro announced a plan to reduce its total workforce by 15% or 900 positions and began by reducing the executive leadership team by 30%, as well as a reducing the number of direct reports to the Vice-Presidents by 40%. At the same time, the Voluntary Departure Program launched, targeting to achieve the remaining position reductions. The target 900 positions are projected to be eliminated primarily in 2017/18 and 2018/19 for cumulative additional savings of approximately $900 million by the end of the 10-year forecast period to 2026/27. MH16 assumes that approximately $700 million are operational savings and the remaining $200 million are related to capital.

In addition to position reductions, MH has committed to achieve procurement savings obtained through supply chain management initiatives. As part of its cost containment strategy, Manitoba Hydro is working to accelerate supply chain management initiatives which have been underway since 2014/15 (as discussed in Section 6.2.5 of Tab 6). From 2017/18 to 2020/21, potential cost savings of $150 million have been identified through a variety of strategic sourcing opportunities using industry specific indices (approximately 70% related to capital reductions and the remaining 30% to operational reductions). Categories include construction and infrastructural services, building and facility construction, contractor and professional services, general hardware, fleet assets and repair, and building material and structures. Strategies for sourcing savings within these categories include amalgamation of contracts to capitalize on volume discounts; optimizing total cost of ownership; rationalizing services through identification of discretionary and critical services; specification refinement/rationalization; and reduction of single source contracts through competitive tenders. By the end of the 10-year forecast period to 2026/27, these savings are expected to accumulate to nearly $450 million.

Lower Electric Load Forecast and Domestic Revenues

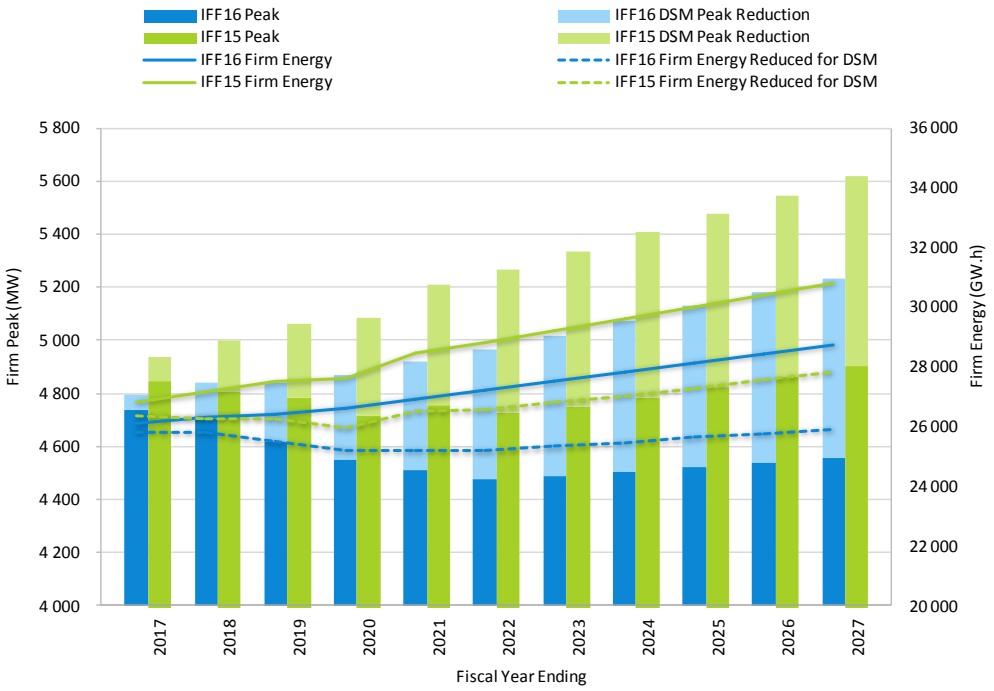
With the timing of the preparation of MH16, the gross firm energy and total peak included in the 2016 Load Forecast were reviewed and adjusted to reflect lower actual usage and weather data available for the 10 months included in 2016/17, as well as anticipated changes for the 2017 forecast related to lower preliminary population forecasts and reduced expectations for new large industrial loads. However, this adjustment does not factor in other potential changes that will be captured in the 2017 Load Forecast. Such changes include the effect of price elasticity regarding the 7.9% proposed and indicative rate increases included in MH16, other updated economic inputs, or other changes in projected consumption that would result in year-to-year variations from the 2016 Load Forecast.

The reduction to gross firm energy from the 2016 Load Forecast is anticipated to be approximately 1,000 GWh by 2035/36 which is equivalent to the 24th percentile probability point of the 2016 Electric Load Forecast based upon the load variability analysis presented at page 44 of the 2016 Electric Load Forecast report (Appendix 7.1 of Tab 7). The 24th percentile point was selected as a proxy for Manitoba's anticipated future load requirements in the 20th year of the 2017 forecast. The following comparisons are made between the 2015 Load Forecast and the 2016 Load Forecast, including the adjustment discussed above.

- Gross firm energy (before program-based DSM initiatives) in Manitoba is forecast to grow on average by approximately 300 GWh or 1.2% per year over the 11-year forecast period to 2026/27.
- Gross total peak is forecast to grow at the same pace as gross firm energy, by approximately 55 MW or 1.2% a year over the 11-year forecast period to 2026/27.
- Compared to the 2015 forecast, gross firm energy is projected to be about 700 GWh (2.6%) lower in 2016/17 primarily due to the lower residential and commercial market sector load experienced in 2014/15 and 2015/16, along with changes in the large industrials short-term plans.
- By 2026/27, gross firm energy is expected to be approximately 2,100 GWh (6.8%) lower in comparison to the 2015 forecast (including the adjustment from the 2016 Load Forecast), primarily due to the reduced expectations for new large

industrial loads and a decrease in the population forecast lowering the residential and commercial market sectors, representing a reduction of approximately five years of load (where 1 year equals approximately 442 GWh).

- Consistent with gross firm energy, gross total peak is forecast to be about 400 MW (6.9%) lower in 2026/27 than the 2015 forecast or a reduction of approximately five years of load growth (where 1 year equals approximately 80 MW).



Savings due to DSM programs to date are embedded in the historical data that is the basis for the Electric Load Forecast. The current level of past achieved DSM savings is assumed to remain in place throughout the future. The Electric Load Forecast reflects future DSM savings associated with existing Provincial building codes and improved equipment efficiency standards and regulations (codes and standards). This is the only effect of DSM initiatives that is specifically accounted for in Electric Load Forecast. Future DSM savings arising from future Power Smart offerings and market engagement above the current level and incremental to the codes and standards are accounted for separately in Manitoba Hydro's Power Smart Plan and Resource Planning Assumptions and Analysis included in Tab 7 of this Application.

On March 9, 2017, the Provincial Government tabled legislation to create a new Crown Corporation – Efficiency Manitoba – which will assume responsibility for efficiency initiatives with an initial focus on reducing electricity and natural gas consumption in Manitoba. Efficiency Manitoba will be mandated to achieve specified energy efficiency targets, which are in excess of those embedded in Manitoba Hydro's existing DSM plan. Under the proposed legislation, Manitoba Hydro will also continue to be responsible for the costs of meeting the legislated targets. While it is uncertain at this time what the impacts of Efficiency Manitoba and legislated DSM targets will be, they have the potential to further reduce domestic load growth in that the proposed legislated targets exceed what Manitoba Hydro anticipates achieving under its current DSM plan. Until the new efficiency entity is in place and the first plan is developed, MH16 continues to incorporate the costs and savings reflected in Manitoba Hydro's current Power Smart Plan in the same manner as previous forecasts.

The 2016 Power Smart Plan targets savings similar to that in the 2015 Plan. The 2016 Plan proposes to realize electricity savings of 1,232 MW and 4,506 GWh, natural gas savings of 130 million cubic meters, and combined global greenhouse gas emission reductions of 3.3 million tonnes by 2030/31 (compared to 1,288 MW and 4,619 GW in electricity savings, 118 million cubic meters of natural gas savings, and combined global greenhouse gas emission reductions of 3.3 million tonnes by 2029/30 in the 2015 Plan).

The following **Figure 3.5** combines the forecast gross energy and peak requirements projected in the Load Forecast with the planned additional DSM energy and capacity savings from the Power Smart Plan. Manitoba Hydro's gross firm energy (lines) and peak (bars) are compared to firm energy and peak net of DSM savings (solid lines and bars, respectively), as well as a comparison between the 2015 (green) and 2016 (blue) forecasts. Energy, net of DSM savings, in MH16 shows no growth over current levels by 2027 compared to 0.5% average annual growth in MH15. MH16 capacity, net of DSM savings, is projected to decline by 0.3% over the 11-year forecast period compared to 0.1% average annual growth in MH15.

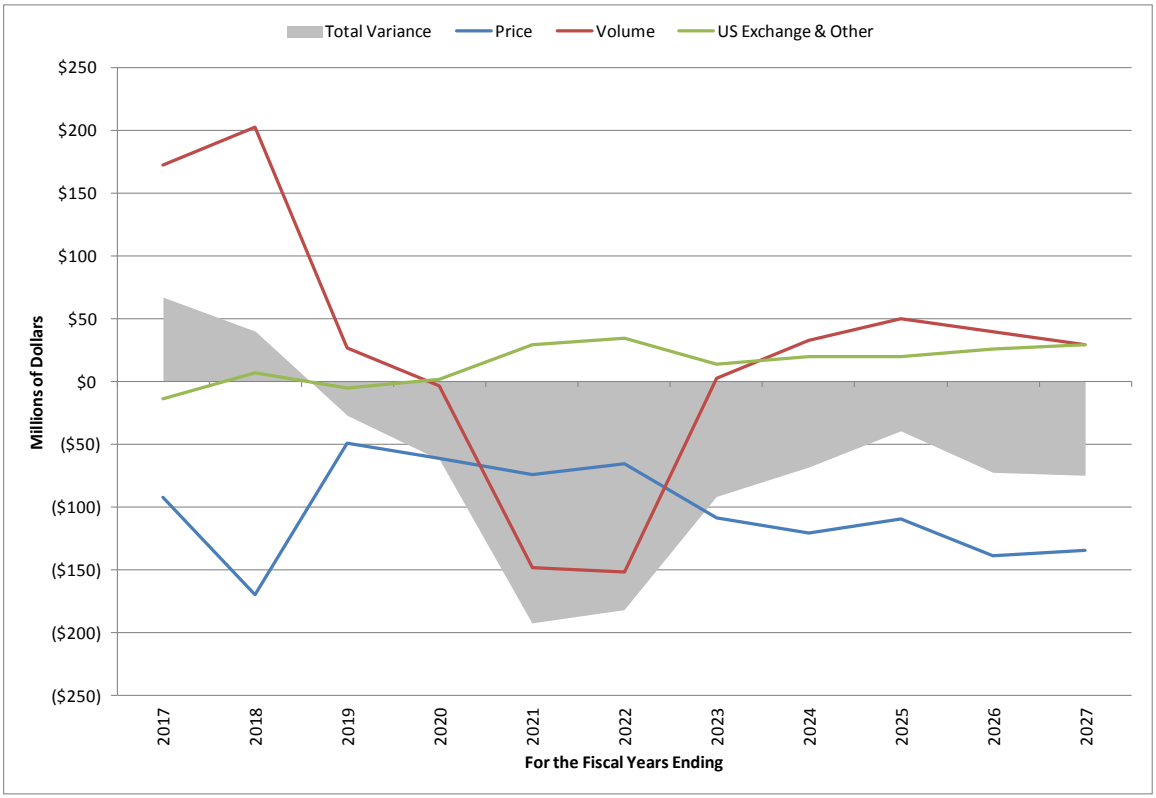


Figure 3.5 Comparison of MH16 and MH15 Firm Energy and Peak

Lower Extraprovincial Revenues

The following **Figure 3.6** shows that MH16 net extraprovincial revenues are $0.7 billion lower compared to MH15 over the 10-year forecast period from 2016/17 to 2026/27 reflected in the grey shaded area ($0.8 billion from 2017/18 to 2026/27).

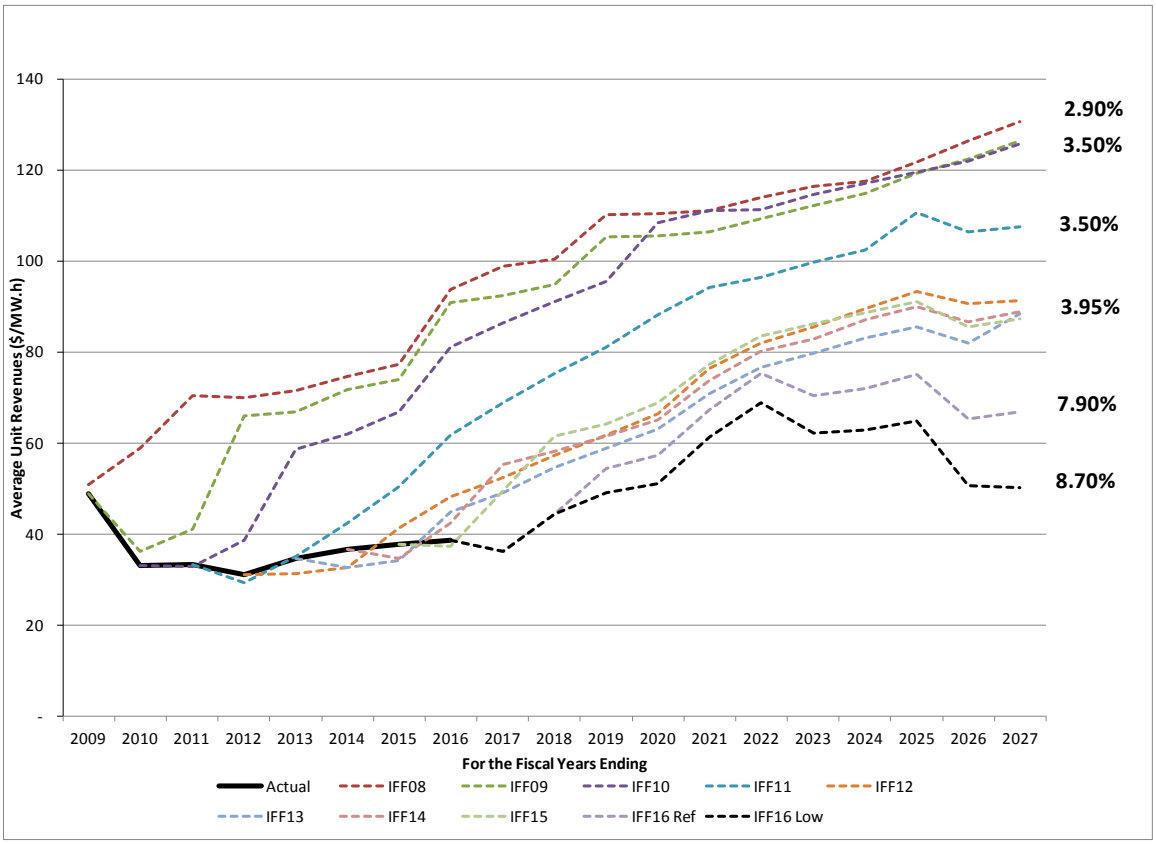

Figure 3.6 – Change in Net Export Revenues in MH16 compared to MH15

The reduction in export prices accounts for about $1.1 billion of the cumulative reduction of net extraprovincial revenues over the 10-year forecast period to 2026/27. MH16 reflects electricity export prices that are lower by approximately 20% relative to the comparable 2015 forecast. The decline to long-term power prices is due primarily to a reduction to long-term natural gas prices and increased renewable development (primarily wind generation) in the MISO market, aided by substantial subsidies. In addition, the premium that has historically been applied to the long-term dependable forecast prices has been removed as the achievability of this premium has reduced significantly in the MISO market. Reflecting the continuing trend of low capacity value, a January 2017 update removed capacity value from the pricing of potential future uncommitted export sales from surplus dependable energy.

The following **Figure 3.7** shows the actual average export prices since 2009 (solid black line) compared to the progression of forecasted average unit revenues since IFF08 (coloured dashed lines) with the projected annual rate increases associated with the respective forecasts.

Figure 3.7 Progression of Forecast Average Unit Revenues Compared to Actual Average Prices

Near term forecasts, particularly IFF12 through IFF15, are relatively accurate as demonstrated by the cluster of dotted lines around the solid black line. Longer term of forecasts prior to IFF12 assumed much higher real price growth.

Compared to IFF08, forecast average unit revenues have decreased by 35% to 60%. Over time as actual prices have remained relatively flat, consultants' forecasts have corrected for the change in natural gas prices, and as a result, the forecast real

electricity price growth has decreased. As expectations for export prices have weakened from forecast to forecast, pressure on domestic customer rates has significantly increased to compensate for lost domestic revenues indicated by the respective rate increase assumptions associated with the forecasts on the right of **Figure 3.7**.

The current reference price forecast assumes moderate real price growth but natural gas futures indicate that the low electricity price trend may continue. However, there is no certainty in the level or duration of low electricity export prices. The IFF16 low price case shown in **Figure 3.7** reflects a scenario in which the current low opportunity prices are sustained and results in 8.7% annual rate increases for five years to maintain comparable forecast equity as the 7.9% base case. By 2026/27, cumulative rates are about 6 percentage points higher.

In addition to lower export prices, **Figure 3.7** shows additional lost net extraprovincial revenues of approximately $0.5 billion compared to MH15 due to the Keeyask 21-month delay. These reductions to net extraprovincial revenues are partially offset by more favourable water flows in 2016/17 and 2017/18 than planned in MH15, as well as more surplus energy available for exports as a result of the reduction in Manitoba Hydro's forecast of Manitoba demand. These changes in volume account for about a $0.8 billion increase in net extraprovincial revenues over the 10-year forecast compared to MH15.

With the reduction in forecasted domestic load and export prices, a higher level of rate increases are necessary compared to previous plans in order to obtain a better financial position. Relying on substantial improvements in export prices or growth in domestic revenues at current approved rates places customers at risk of rate shock if these export prices do not rebound or other risks materialize.

3.2.2 Capital In-Service

While assets are under construction, the capital expenditures and associated financing costs are held in construction work in progress. Once these assets are placed into service, the associated carrying costs (depreciation and finance expense) form part of the Corporation's revenue requirements.

Figure 3.8 provides a summary of the amount of capital that is forecast to go in service, as well as deferred assets that will commence amortization for the first three forecast years as well as the 10-year forecast period. **Figure 3.8** indicates that $0.9 billion, $0.7 billion and $5.5 billion of assets are projected to be placed in-service in 2016/17, 2017/18 and 2018/19, respectively. The most significant asset being placed in-service during this period includes the Bipole III Reliability Project in 2018/19. In this three year period, there is also approximately $1.7 billion of sustaining capital expenditures and $0.3 billion of DSM expenditures that will be placed into service; $0.2 billion of these DSM expenditures will commence amortization.

Figure 3.8 Electric Capital In-Service Amounts

3.2.3 Accounting Assumptions in IFF16

Manitoba Hydro is seeking PUB endorsement of proposed deferral and amortization of costs incurred with respect to Conawapa as well as endorsement of the proposed amortization period for disposition of regulatory deferral accounts, which are included in MH16's DSM & Other Assets capital in-service amounts outlined in **Figure 3.8** above. The annual adjustments to regulatory deferral balances arising in net movement consist of additions to regulatory deferral balances and the amortization of such balances. A positive net movement balance adds to net income, while a negative balance will subtract from net income.

The regulatory deferral account for Electric Operations include Power Smart program expenditures, site restoration expenditures for the remediation of contaminated corporate facilities and diesel generating sites, the Affordable Energy Fund, net asset retirement losses, regulatory costs, and differences in depreciation and overhead capitalized used for financial reporting versus rate-setting purposes.

Treatment of Costs Incurred for Conawapa Generating Station

Manitoba Hydro is seeking PUB endorsement of the proposed inclusion of costs incurred with respect to the Conawapa Generating Station project into Manitoba Hydro's regulatory deferral balances and subsequent amortization.

Manitoba Hydro wrap-up activities with respect to design, consultations and environmental studies following the Province's 2014 direction to suspend development of the Conawapa Generating Station were completed as at December 31, 2016. Manitoba Hydro has ceased capitalization of interest as of the completion date and total costs (including interest) are $380 million, which are currently reflected in Manitoba Hydro's construction in progress balance.

Any short-term decisions as to whether to restart or continue to suspend Conawapa depends on whether or not federal and/or provincial carbon reduction initiatives materialize to the point where a future export sales arrangement can be secured to support the economics of constructing this plant. Since there is significant uncertainty as to the timing of such initiatives and their impact on potential export sales arrangements, no further activities are planned for Conawapa. As a result, it has

become increasingly difficult to demonstrate future benefits to Manitoba Hydro's auditors, and Manitoba Hydro will be required to recognize the $380 million in costs to net income for financial reporting purposes under IFRS. To minimize the impact on customers, Manitoba Hydro is proposing to defer these costs in a regulatory deferral balance and commence amortization over 30 years, subject to the PUB's endorsement following its review of Manitoba Hydro's 2017/18 and 2018/19 GRA. MH16 assumes Conawapa costs are recognized in the regulatory deferral balance and amortization commences effective April 1, 2019.

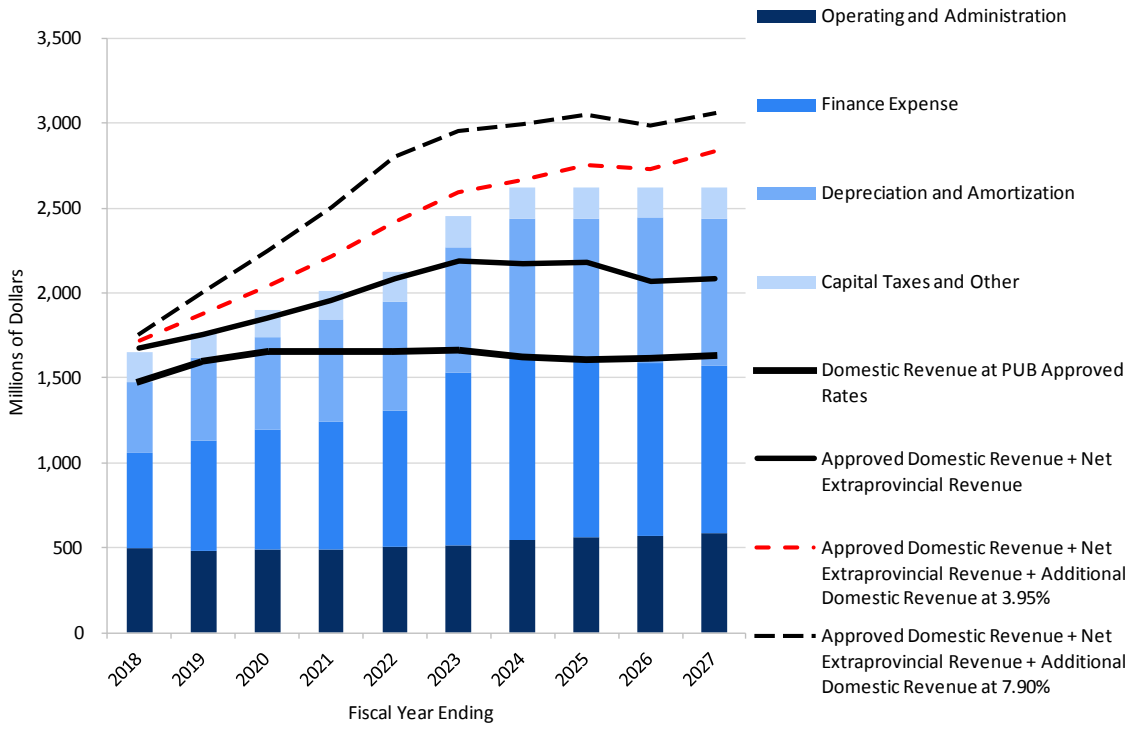
Regulatory Deferral Account - Depreciation

MH16 includes a regulatory deferral account reflecting the difference between depreciation calculated using the ELG depreciation method for financial reporting purposes and the ASL method used for rate-setting purposes.

In Order 73/15, the PUB directed Manitoba Hydro to continue to use the CGAAP ASL method of depreciation for rate setting purposes until the PUB is satisfied that a change in depreciation methodology is warranted. As Manitoba Hydro uses the ELG depreciation method for financial reporting purposes, MH16 assumes that the differences between these depreciation methodologies will accrue to a regulatory deferral account until March 31, 2023, the fiscal year end of the last Keeyask unit in-service. Thereafter, net income is sufficient to absorb the difference in methodologies without adverse impact to the projected inflationary rate increases.

The regulatory deferral balance for ELG depreciation expenses grows to $300 million by the final Keeyask unit in-service in 2022/23. As a result, Manitoba Hydro is seeking endorsement from the PUB to commence amortization of the ELG regulatory deferral balance over 20 years in 2017/18. Section 10.4.4 in Tab 10 provides additional discussion with respect to Manitoba Hydro's response to the PUB's directive in Order 73/15 related to depreciation.

Regulatory Deferral Account – Overheads not Eligible for Capitalization



MH16 also includes a regulatory deferral balance for $20 million in annual overhead costs ineligible for capitalization under IFRS to be deferred for rate-setting purposes in accordance with the PUB's findings in Order 73/15. Consistent with the treatment of

depreciation expenses, MH16 continues to defer ineligible overhead costs until March 31, 2023. At this time, the ineligible overhead deferral balance grows to approximately $160 million and Manitoba Hydro is seeking PUB endorsement to commence amortization of this balance over 20 years in 2017/18.

3.2.4 10-Year Comparison of Carrying Costs vs. Revenues

The following **Figure 3.9** compares Manitoba Hydro's electric operations projected carrying costs (O&A, finance expense, depreciation expense, and taxes and other expenses) arising from assets placed into service to the Corporation's projected domestic and net export revenues (extraprovincial revenues less fuel and power purchases and water rentals and assessments).

Figure 3.9 Comparison of MH16 Capital Carrying Costs to Revenues

Manitoba Hydro's costs rise sharply to $2.6 billion over the 10-year period to 2026/27, increasing by about 60% from their current level of $1.5 billion. Despite the significant increase in Bipole III and Keeyask project costs, MH16's carrying costs are lower compared to MH15 ($2.8 billion by 2026/27).

Domestic revenues are insufficient to fully absorb the $1.0 billion carrying cost increase. Over the 10-year period, domestic revenues, including the previous forecast's annual 3.95% rate increases, are barely sufficient to cover carrying costs and do not support equity growth consistent with the growth in assets or net debt, leaving Manitoba Hydro's customers exposed to the significant risks faced by the Corporation.

Manitoba Hydro's previous forecast predicted domestic load growth of 1.6% over the next 10 years, and export price appreciation that would result in a positive forecast net income and equity growth in the longer term. These assumptions allowed Manitoba Hydro to maintain its forecast of even annual rate increases at 3.95% to 2028/29 in order to defer or avoid seeking higher rate increases than what would otherwise be required.

Manitoba Hydro accepted a significant deviation from its financial targets in past forecasts in order to alleviate rate increases in excess of 3.95% to the extent possible. Manitoba Hydro's projected financial results have fortunately benefited from exceptional water flow conditions and the current low interest rate environment. Should these fortunate circumstances suddenly or adversely turn around, or the major projects experience further cost increases, Manitoba Hydro cannot rely on the optimistic anticipation of increased domestic or export revenues given the flat forecast of domestic load and the flatter forecast of opportunity export prices (relative to previous forecasts) to reduce the significant pressure that will be placed on future customer rate increases. The advancement of rate increases in MH16 reduces the future debt burden, thereby, reducing the future rate pressure on customers.

The proposed rate trajectory reflected in MH16, combined with Manitoba Hydro's accelerated cost reductions, will place Manitoba Hydro in a better financial position to deal with significant potential financial risks (drought, rising interest rates and lower export prices) without having to rely on large, unplanned rate increases to sustain operations.

3.3 DEBT MANAGEMENT STRATEGY

The Debt Management Strategy document (see Appendix 3.5) provides information on the historical growth of the Corporation's investment in fixed assets and the corresponding increase in Manitoba Hydro's long term debt. The document also summarizes the statutes that govern the Corporation's financing programs, and outlines the debt management strategies that will address the Corporation's financing requirements for the 2017/18 and 2018/19 fiscal years.

Manitoba Hydro's fundamental debt management objective is to provide low cost, stable funding to meet the financial obligations and liquidity needs of the Corporation.

In order to reduce the interest rate risk on the existing total debt portfolio, Manitoba Hydro will maintain its percentage of floating rate debt within the portfolio at or below 10%. To mitigate the pressure on Manitoba credit spreads, the Corporation will also undertake a variety of debt management activities such as establishing benchmark sized debt issues and diversifying the investor base by continuing to issue Manitoba bonds into international markets. To mitigate liquidity risk and provide financing flexibility to secure debt during periods of constructive investor tone, Manitoba Hydro also intends to maintain unencumbered positive cash balances by securing funds approximately three months in advance of its cash requirements.

With the potential availability of cash following the in-service of new major generation and transmission, an opportunity exists to use this future cash to retire debt at that time. This debt off-ramping is a key factor in the planned reduction in finance expense and the recovery of Manitoba Hydro's financial ratios.
