SUMMARY OF RESULTS

SUMMARY OF RESULTS

1. The average reservoir pressure (P_R) is 3 423 kPa.

2. The effective permeability to oil of the Spearfish formation is 11.6 mD.

3. The apparent wellbore skin factor of -2.6 confirms was stimulated.

4. Production forecast sensitivity indicates that the well will start declining after approximately 8 months.

5. The IPR plot indicates a maximum theoretical stabilized oil rate (AOF) of 3.7 m^3/d.

6. Radius of investigation is approximately 38 m.

TEST ANALYSIS

DISCUSSION

1. Test Overview:

The Home Pierson 15-09-02-29W1 is completed in the Spearfish formation at 1020 - 1025 mKB and is equipped with a 60.3 mm tubing. The well was fractured during the initial completion to improve productivity.

During the test, the well produced at an oil rate of 3.6 m^3/d. Subsequently, the well was shutin for a 356 hour buildup period. The bottom hole pressures were calculated from the measurement of liquid levels, obtained from the Acoustic Wellsounder equipment by Otatco Inc. The oil gravity is 36 API. Other oil physical properties were calculated using various standard correlations.

2. Data Validation:

During the test, bottom hole pressures were measured using the Acoustic Wellsounder equipment.

The primary pressure derivative (PPD) plot was constructed for the measured pressures (Figure 1) as shown in the Section "Test Data Quality". The PPD showed only minor pressure anomalies. The PPD plot should be monotonically decreasing with time for valid buildup data. Pressure data was reported in absolute at MPP.

TEST INTERPRETATION

1. Pressure Buildup Analysis:

Pressure buildup analysis was performed on the shut-in period. The reservoir parameters were provided by Anderson Exploration Ltd., as shown in the attached form "Summary of Test Data and Results". The final oil rate flow rate prior to shutting in the well was 3.6 m^3/d at a sandface flowing pressure of 403 kPa, as shown in the Strip Chart (Figure 2) in the section "Pressure Transient Analysis".

Both the Horner Plot and the pressure derivative analysis were used in the analysis, as discussed below, and results were later fine tuned using the pressure history match techniques of the test pressure data.

Wellbore storage regime was identified by the unit slope straight of the pressure derivative as shown in the Diagnostic Derivative Analysis plot (Figure 3) in the section "Pressure Transient Analysis". The flattening of the pressure derivative, of the late time data, confirms that radial flow was reached.

Radial flow analysis was performed to determine the reservoir parameters using the semi-log straight line drawn through the late time pressure data, as shown in the Horner plot (Figure 4). The extrapolation of the last data points yielded a P^* of 3 903 kPa. The (P^*) was corrected for the shape, areal extent of the reservoir and the location of the well to determine the average reservoir pressure of 3 870 kPa. The results of the Horner plot and the pressure derivative are summarized below:

	Horner	Derivative
Effective Permeability, mD	9.6	10.3
Reservoir Pressure, kPa	3 870	n/a
Apparent Skin Factor	-3.0	-2.8

2. Pressure History Match:

The preliminary results from the Horner analysis were used as starting parameters for pressure history matching of the test data. The best match of the test data was obtained, using the Wellbore Storage/Skin Model. The overlay of simulated analysis results on the real test data is presented in the cartesian, semi-log and log-log plots (Figures 5, 6, and 7), in the section "Pressure History Match". The parameters used to achieve the history match are as follows:

	History Match	
Reservoir Pressure, P_r	3 423	kPa
Effective Permeability, k	11.6	mD
Skin Factor, S	-3.5	
Six-Month Stabilized Rate, q_s	3.5	m^3/d

3. Inflow Performance Relationship (I.P.R)

The Inflow Performance Relationship (I.P.R) was constructed using the Vogel equation, as shown in Figure 8, in the Section "I.P.R". The average reservoir pressure of 3 252 kPa and the test data were used to generate the I.P.R plot, at the current skin factor of -3.5. The well maximum theoretical oil rate is 2.7 m^3/d.

4. Production Forecast Sensitivity Analysis:

Production forecasts were generated for the well using the reservoir parameters obtained from the test history match. Sensitivity analysis was performed in attempt to maximize the oil recovery and to establish a reasonable gas production plateau. The bottom hole flowing pressure (BHFP) was used as a sensitivity parameter, and the various generated production forecasts are shown in Figure 9 in the section "Pressure History Match".
